

This is a digital copy of a book that was preserved for generations on library shelves before it was carefully scanned by Google as part of a project to make the world's books discoverable online.

It has survived long enough for the copyright to expire and the book to enter the public domain. A public domain book is one that was never subject to copyright or whose legal copyright term has expired. Whether a book is in the public domain may vary country to country. Public domain books are our gateways to the past, representing a wealth of history, culture and knowledge that's often difficult to discover.

Marks, notations and other marginalia present in the original volume will appear in this file - a reminder of this book's long journey from the publisher to a library and finally to you.

### **Usage guidelines**

Google is proud to partner with libraries to digitize public domain materials and make them widely accessible. Public domain books belong to the public and we are merely their custodians. Nevertheless, this work is expensive, so in order to keep providing this resource, we have taken steps to prevent abuse by commercial parties, including placing technical restrictions on automated querying.

We also ask that you:

- + *Make non-commercial use of the files* We designed Google Book Search for use by individuals, and we request that you use these files for personal, non-commercial purposes.
- + *Refrain from automated querying* Do not send automated queries of any sort to Google's system: If you are conducting research on machine translation, optical character recognition or other areas where access to a large amount of text is helpful, please contact us. We encourage the use of public domain materials for these purposes and may be able to help.
- + *Maintain attribution* The Google "watermark" you see on each file is essential for informing people about this project and helping them find additional materials through Google Book Search. Please do not remove it.
- + *Keep it legal* Whatever your use, remember that you are responsible for ensuring that what you are doing is legal. Do not assume that just because we believe a book is in the public domain for users in the United States, that the work is also in the public domain for users in other countries. Whether a book is still in copyright varies from country to country, and we can't offer guidance on whether any specific use of any specific book is allowed. Please do not assume that a book's appearance in Google Book Search means it can be used in any manner anywhere in the world. Copyright infringement liability can be quite severe.

### **About Google Book Search**

Google's mission is to organize the world's information and to make it universally accessible and useful. Google Book Search helps readers discover the world's books while helping authors and publishers reach new audiences. You can search through the full text of this book on the web at <http://books.google.com/>

THE  
**Medical Press**  
and Circular. Estab. 1838.

Being the Incorporation of the Journals hitherto known as "The Medical Press  
and "The Medical Circular."

A Weekly Journal

OF

MEDICINE AND MEDICAL AFFAIRS.

FROM JULY TO DECEMBER,

1904.

LONDON : 8 HENRIETTA STREET, STRAND; DUBLIN : 16 LINCOLN PLACE.

## I N D E X.

VOL. LXXVIII NEW SERIES. (VOL. CXXIX OLD SERIES.)

JULY TO DECEMBER, 1904.

- A medical hero, 375  
A strange congress, 230  
Aarons, Dr., a new uterine mop, 485  
Abdominal abscess, Dr. Tuffler, 193  
Abdominal venosity, "good capon head," 207  
Aberdeen University (pass list), 109  
Abolition of sea burial, 608  
Abraham, Dr., dermatological cases, 360  
Abuse of hospitals, 524  
Accidental hæmorrhage, treatment of, 176  
Acetopyrine, 466  
Acetozone, 561  
Acetozone, Dr. Burnet (illustrated), 165  
Acne vulgaris, 575  
Acneiform tubercles of the skin, 67  
Acromegaly, 13  
Action against Sir P. H. Watson, 557  
Action for malpraxis, 134  
Action of digitalis, 362  
Action of sugar on the uterus, 638  
Activity of fluorescent substances, 42  
Acute rheumatism, 310  
Acute rheumatism in childhood, 574  
Acute yellow atrophy of the liver, Dr. Thompson, 594  
Adenoma hæmorrhagica of the endometrium (illustrated), Dr. Alexander, 649  
Administration of the R.A.M.C., 177  
Adrenalin, 66  
Adrenalin inhalant, 561  
Adrenalin ointment, 561  
Aerophagy, 500  
Age limit for the staff of the Royal Infirmary, Edinburgh, 558  
Age limit, the, 530  
Aids to dissection, 23  
Aix-la-Chapelle, 40  
Albuminuria, 632  
Alcohol as a food, 490  
Alcohol of tremor, 640  
Alcoholic automatism, 608  
Alcoholic insanity, 616  
Alcoholic treatment of erysipelas, 412  
Alcoholism and insanity, 368, 391  
Aldershot poisoning outbreak, 528  
Alexander, Dr., adenoma hæmorrhagicum of the endometrium (illustrated), 649  
Allen lunatics, 239  
Alkaptonuria, 604  
Alleged unauthorised post-mortem, 180  
Allsopp's lager beer, 561  
Almatin, 466  
Alterations in examination of the Royal University, Ireland, 641  
Amoebial enteritis, 172  
An eventual career, 125  
Anæsthesia in operations on the nasopharynx, 499  
Angina ulceroza, 663  
Angostura bitters, 78  
Ankylostomiasis, 351  
Annual meeting of the British Medical Association, 29  
Annual meeting of the R.C.S.Eng., 576  
Another drink cure, 230  
Another tuberculous cure, 548  
Anthelmintics in children, 225  
Anthrax, death from, 160  
Antiseptic barber, 608  
Antiseptic value of iodoform, 340  
Antistreptococcus serum and rheumatism, 145  
Aphasia, 66  
Apothecaries' Hall, Ireland, 335  
Appendicitis, 173  
Army Medical Service (pass list), 161  
Arterio-sclerosis, 438  
Artificial production of leucæmia, the, 341  
Ashmead, Dr., influence of nuclein in Bright's disease, 370  
Aspects of overcrowding, some, 636  
Aspiration of the cranium, 42  
Association of Port Sanitary Authorities, 521  
Athletics and health, 99  
Australian surgery thirty years ago, 369  
Awards at the St. Louis Exhibition, 451, 461  
B. Eucaine (lactate Schering), 506  
Backache, 40  
Bacteria in the stomach, 640  
Bacterial action of typhoid, 467  
Bacteriological Institute in Madras, 229  
Bacteriological section of the King Institute, Madras, Lieut.-Col. Christophers, 220  
Bacteriology of pertussis, 367  
Bacteriology of pneumonia, 48  
Bad hæmorrhoids, Dr. J. W. Martin, 143  
Bangour Asylum, 582  
Banks, Sir W. M., the late, 611  
Badly ventilated schools at Burnley, 618  
Barandt, Dr., vestiges of syphilis, 36  
Barker anatomical prize, 108  
Barlow's disease, 663  
Bath, 515  
Bathing during menstruation, 127  
Bechterew's reflex, 339  
Beck's, Mr., double, 607  
Bedding and disease, 371  
Belfast District Lunatic Asylum, 261  
Belfast guardians, 422  
Belt in whooping-cough, the, 499  
Bequests to medical charities, 239, 351, 380  
Beri-beri as an epidemic, 71  
Beri-beri, diagnosis of, 50  
Birds and mammalian tuberculosis, 548  
Birmingham University (pass list), 135  
Births—end of each No.  
Bishop Teignton, 117  
Biss, Dr. H., preventive treatment of scarlet fever, 215, 241  
Bleeding hæmorrhoids, 310  
Bleeding piles, 145  
Blood-letting in eclampsia, 490  
Blood pressure, 549  
Bob Sawyer—*ad nauseam*, 668  
Boric acid and kidney disease, 393  
"Borstal" system, the, 468  
Bovinine, 78  
Boyd, Dr., classification of pauper consumptives in Irish workhouses, 432  
Brachycardia, 362  
Brackett, Dr., suppurative knee-joint, 167  
Bradshaw lecture, Mr. M. Robson, 595  
"Breathing out slaughter," 341  
Brenner Bad, 65  
Bright's disease, Dr. Chrysovergis, 247  
British health resorts, 39, 64, 91, 117, 144, 170, 197, 223, 250, 309, 332, 360, 385, 486, 515, 541  
British Medical Association's annual meeting, 102, 121, 129, 154  
Bromo-derma tuberosum, 119  
Browne, Sir Thomas, 255  
Brutality of kindness, 219  
Bubonic plague in the Tyne, 365  
Budgeigh Salterton, 91

### PESSARIES :

#### THEIR USES AND LIMITATIONS. (a)

By ARTHUR E. GILES, M.D., B.Sc., F.R.C.S.,  
Surgeon to Out-Patients, Chelsea Hospital for Women; Gynaecologist  
to the Tottenham Hospital.

IN considering the question of pessaries, it is well that we should firmly grasp the principles underlying their use in the treatment of displacements of the female pelvic organs. Briefly, their uses are :—

1. To effect a cure, as in some cases of backward displacement, where the uterus may be expected to retain its proper position unaided, after it has been maintained in that position for some time by means of a pessary.
2. As a temporary expedient, whilst waiting for operation, and in cases of retroversion of the gravid uterus, where the normal position will be maintained when the uterus has attained a certain size.
3. As a palliative measure, when radical, that is, operative, treatment is impracticable, undesirable, or declined by the patient.

These are the broad principles ; and the precise indications will be presently set forth in detail.

Before proceeding further, we must disabuse ourselves of certain fallacies, which appear to be widely spread and deeply rooted in the minds either of the public or of members of our profession. Among these fallacies we may signalise the following :—

That the vagina is a natural predestined receptacle for a pessary of some kind.

That the vagina is a grave in which a pessary may be interred, undisturbed, and without hope of resurrection.

That a pessary is a good and proper placebo in all obscure and intractable disorders of the pelvic organs, and in nervous disturbances generally.

That anteversion of the uterus is a displacement.

That a rubber ring pessary is generally serviceable in backward displacements.

That a displacement necessarily requires local treatment.

Another fallacy formerly in vogue, if we may judge by what we may see in instrument-makers' catalogues, but now, I think, relegated to the limbo of discredited traditions, is the supposition that the first stage in the career of a would-be women's specialist is the invention of a new pessary or the modification of an old one.

Pessaries are not an unmixed blessing to woman-

kind ; they have drawbacks and potential risks ; but as they are necessary in certain cases, we may qualify our disapproval of them by describing them as a necessary evil. In some cases where their use might be otherwise called for, there are definite contra-indications. Among these we may enumerate the following :—All inflammatory conditions of the pelvic organs, including vaginitis, endometritis, pelvic peritonitis and cellulitis ; and inflammatory disease of the appendages, ulceration of the vagina, erosion of the cervix, pregnancy in the later months, displacements due to tumours, and incorrigible displacements, namely, such as are associated with fixation due to adhesions. I have several times had occasion to remove a pessary from a case in which the fundus of the uterus was firmly held by adhesions in the pouch of Douglas. I have removed pessaries from cases where the instrument was lying in a pool of muco-pus derived from a raw, red erosion of the cervix, and I have found them adding to the discomfort of a patient with a uterine fibroid, when there was barely room for the uterus and tumour. It may appear superfluous to suggest that a normal condition of the pelvic organs is a contra-indication to the use of a pessary ; yet I have not infrequently removed supports, generally rubber rings, from cases where every organ was normal and in good position. These have generally been neurotic cases, where no doubt the medical attendant has despaired of relieving the multifarious aches and pains complained of, and has introduced a pessary as a sort of placebo, a material sign on which the patient may rest her faith that she is getting better. In my experience, the more normal organs are interfered with in the hope of relieving obscure symptoms, the worse do those symptoms become. All these are instances of the abuse of pessaries. Properly-fitting pessaries, rightly applied, in suitable cases, have enough to answer for in the way of drawbacks and complications, without the reputation of this therapeutic measure being further damaged and prejudiced by their use in unsuitable and normal cases.

*Indications for the Use of Pessaries.*—I now pass on to consider the conditions where pessaries are of service, and the particular kind to be used in each case. These conditions fall into three classes, which may, however, be more or less combined :—

1. Hernia of the vaginal walls, that is, cystocele and rectocele.
2. Prolapse and procidentia of the uterus.
3. Backward displacements of the uterus.

1. *Hernia of the Vaginal Walls.*—In uncom-

a) A Paper read before the North-East London Clinical Society.

plicated cases of cystocele and rectocele, a rubbering pessary usually answers best, whether there be a cystocele alone, a rectocele alone, or a combination of the two. But in some cases of cystocele a ring does not answer, owing to the tendency of the anterior vaginal wall to slip down in front of the pessary; and I have then sometimes found an inverted Hodge, with a single curve, meet the case. When a rubber ring is used, it should be thick in section, as in the Meyer pattern; if a large, thin ring be introduced, the vaginal wall will come down through it. Solid wooden or vulcanite rings should be avoided, because during their introduction and removal they stretch the vaginal orifice unduly. Sometimes the perinæum is so deficient that the vaginal orifice is the widest part of the passage; in such a case no ring will keep *in situ*, any more than a ball could be held up in a hollow cone whose apex was upwards. We must then rely on some kind of vaginal stem-pessary, such as Napier's, held in position with perineal bands fastened to a band round the waist.

2. Cystocele and rectocele are frequently combined with *prolapse and procidentia of the uterus*; or the uterus may descend without the vaginal walls being affected, otherwise than secondarily. In any case the uterine displacement is the one which calls for treatment, and the vaginal condition will be treated incidentally, and at the same time.

For prolapse, that is, descent of the uterus within the vagina, a rubber ring usually answers best. But if the perinæum be deficient, we shall require a Napier pessary, or other vaginal stem-pessary. Sometimes the perineal bands are not well borne, as they may cause chafing and irritation; and we may then have to resort to that makeshift of therapeutic insolvency, a Zwancke pessary, or to that other refuge of the destitute, a Gariel's air-pessary. The effect of the latter is to keep the vagina in such a chronic state of distension that the natural shrinkage of the vagina incidental to the climacteric, which is looked to as the means of bringing about an ultimate spontaneous cure, is thwarted indefinitely.

For procidentia, that is, descent of the uterus outside the vagina, we have to proceed somewhat as for prolapse, with this difference, that the vaginal orifice is so stretched by the descent of the uterus that no ring will keep in at first. But, unless the perinæum has been much torn, if the patient be kept in bed for a week or so, and the uterus remains within the vagina, the orifice will usually contract again sufficiently to retain a rubber ring.

3. *Backward Displacements of the Uterus.*—This is the class of displacement most difficult to deal with. In uncomplicated cases, where the uterus is mobile, and has not been long out of place, a cure may not infrequently be obtained by means of a well-fitting Hodge pessary, or one of its modifications, such as an Albert Smith, a Thomas or a Braxton Hicks. In the two latter forms, the posterior bar, which rests in the posterior fornix, is thickened. There are various conditions, however, which make for failure. If the retroversion has existed long, the uterus may attain a condition of hyperplasia, and the heavy fundus then topples backwards over the pessary. If one or both ovaries be prolapsed, the Hodge is liable to cause such painful pressure that its use has to be discontinued. If there be cicatricial contraction obliterating the

posterior vaginal fornix, or forming bands across it, a Hodge is unavailing. I recently had such a case in the hospital, where an antero-posterior band stretched across the fornix from the apex of the cervix, and the only possible way of correcting the displacement was by ventrofixation of the uterus, which was accordingly done. If the uterus be the subject of a congenital retroflexion, we may push the organ somewhat forward, but the retroflexion will remain, and undo our work. For such a condition, pregnancy is the best cure. Lastly, if the uterus be held down by adhesions to the floor of the pelvis, pessary treatment is out of the question. I have no confidence in the plan (which has been proposed) of forcibly breaking down adhesions by manipulation; to tear a hole in the bowel by such manœuvres would not be a difficult matter.

I may say here that it is bad practice to introduce a Hodge or other pessary without first correcting the displacement, in the hope, which is a vain one, that the constant pressure of the instrument will gradually overcome the resistance. By such a course we merely add risk to inefficiency.

*Precautions to be Observed in the Use of Pessaries.*—The first thing, as I have just remarked, is that the displacement should be corrected. In selecting a pessary, some consideration should be given to the material. A non-absorbent surface is best, therefore hard rubber, vulcanite, celluloid or block tin may be chosen. The next thing is to see that the pessary is a proper fit; if too large it will cause injurious pressure, if too small it will be inefficient. But in case of doubt it is better to err in the first instance in the direction of under-size. The patient should be seen again within a week, in order that the efficiency of the pessary may be tested. A pessary tends to favour leucorrhœa, and also to retain the secretion, and therefore the patient should be instructed to use a douche at intervals. For this purpose plain water or boracic lotion is best; astringent lotions are to be avoided, because they tend to coagulate the secretion on the pessary, which thus becomes coated over with a medium highly favourable to the ubiquitous bacillus. The patient must be firmly impressed with the necessity for periodic inspection. My rule is two to three months as the longest interval. The object of the inspection is that the pessary may be properly cleaned, that its efficiency in maintaining the normal position of parts may be watched, that it may be removed when it appears probable that this can be done without a return of the displacement, and that we may have early warning of any untoward results of the sojourn of the pessary in the vagina. The importance of the last point may be judged of from what I have now to say of the drawbacks resulting from retained pessaries.

*Injuries Due to Neglected Pessaries.*—Some years ago I published some observations on this subject, and I can best illustrate my present remarks by reproducing a table of twelve cases that came under my notice.

Harm is produced in one of three ways: (a) misfit; (b) sepsis; (c) narrowing of the vaginal orifice. The precautions to be used against the first two have been mentioned. Narrowing of the vaginal orifice occurs normally after the menopause; in the case of women who are not living a conjugal life, it may become very marked, so that if a

TABLE OF CASES OF RETAINED PESSARY.

CASE.	AGE.	S M W	CONDITION FOR WHICH PESSARY WAS WORN.	VARIETY OF PESSARY.	LENGTH OF TIME WORN.	INJURY PRODUCED BY THE PESSARY.
1	64	W	"Falling of the womb"	Thick wooden ring	12 years	Purulent vaginitis; incarceration of pessary; extraction under ether necessitating tearing of vulva.
2	35	S	Not known	Vulcanite Hodge	6 months	Grooving and ulceration of left lateral vaginal fornix.
3	57	M	Procidentia	Rubber ring	4 years	Purulent vaginitis.
4	64	M	? Procidentia	Rubber ring	3 years	Purulent vaginitis; urethritis; ulcerated patch, posterior vaginal fornix.
5	30	M	Not stated	Rubber ring	1½ year	Purulent vaginitis.
6	74	M	Prolapse	Rubber ring	12 years	Purulent vaginitis.
7	72	M	Not stated	Blackbee's	8 or 9 years	Horse-shoe shaped ulcerated groove involving vaginal vault and lateral walls; vesico-vaginal fistula.
8	26	M	Retroversion	Block tin Hodge	6 months	Grooving and ulceration of right lateral fornix; fusion of edges of groove forming a band anchoring the pessary.
9	45	S	Not stated	Rubber ring	3½ years	Purulent vaginitis; excoriations of posterior vaginal walls.
10	71	M	Procidentia	Vaginal stem-pessary	6 weeks	Purulent vaginitis.
11	46	M	Retroversion	Vulcanite Hodge	3 months	Grooving and ulceration of posterior vaginal fornix.
12	45	M	Procidentia	Zwancke's pessary	"many years"	Purulent vaginitis; proliferation of granulations with formation of fibrous bands passing through the perforations in the pessary and connecting anterior and posterior vaginal walls.

pessary has been introduced and left for five or ten years it may be found impossible to remove it without a good deal of injury to the tissues of the vulva. This is what happened in Case 1. Apart from the inconveniences arising from this natural involution, the injuries produced are as follows:—The first thing is vaginitis, which soon assumes a purulent form. This may occur as a result of want of cleanliness, even when an instrument fits tolerably well; and hence it is the most common and sometimes the only condition produced by rubber rings, as in Cases 3, 5, and 6. The vaginitis may be associated with urethritis, as in Case 4. Then ulceration may supervene, either in patches, when due to a rubber ring, as in Cases 4 and 9, or in the form of a groove, in the case of a hard, narrow instrument, when localised pressure evidently plays an important part. In this way were produced the injuries in Cases 2, 7, 8, 9, and 12. The grooves become lined with granulations which tend to grow up around the pessary, and may at length grow over, partly imbedding the instrument, as in Cases 2 and 7; or may fuse, forming a bridge of tissue firmly holding the pessary to the vaginal wall, as in Case 8. Or, again, in the case of a flattened pessary with perforations, the granulations may sprout and project through the perforations, forming bands between the anterior and posterior vaginal walls, as in Case 12.

The situation of the grooving will depend on the shape and position of the instrument. In the case of a Hodge pessary, the posterior vaginal fornix is most apt to suffer. A vaginal stem-pessary will affect the tissues round the cervix. The Blackbee's pessary in Case 7 produced a quite special lesion. This instrument used to be employed for anteversion, when this was considered a pathological condition, and it rests partly in the anterior fornix,

and partly against the lateral vaginal walls; and in these positions the ulcerations had occurred. Ulceration in the anterior fornix is almost certain to lead to the serious condition of vesico-vaginal fistula, as occurred in this case. A recto-vaginal fistula might similarly result from ulceration of the posterior vaginal wall. The dangers of retained pessaries may thus be summed up as:—

- a. Purulent vaginitis.
- b. Urethritis.
- c. Ulceration of the vagina.
- d. Imbedding of the pessary in the vaginal tissues.
- e. Vesico-vaginal fistula.
- f. Recto-vaginal fistula.
- g. Incarceration of the pessary from narrowing of the vaginal outlet.

*Alternatives to the Use of Pessaries.*—We have seen that at their worst pessaries are capable of producing serious injuries; at their best they have certain inherent drawbacks. Thus there is the tendency to set up irritation, resulting in constant leucorrhœa and entailing the necessity for regular douching; there is the necessity for examination and manipulation at more or less frequent intervals, which most women naturally find very objectionable; there is the uncertainty of results; and lastly, in favourable cases there is the prospect of a woman having to wear a pessary for ten, fifteen, or twenty years.

With a mode of treatment that is open to such an indictment, it is not surprising that alternative plans have been sought. For some cases, as I have said, pessaries remain the only treatment; but there is no doubt that the modern tendency is to restrict their scope, and to regard many forms as obsolete. Pessaries were introduced when no operative radical treatment was known or practicable. Anæsthetics, antiseptics and

improved *technique* have quite altered this. It is not within the scope of these observations to embark in detail upon the question of the treatment of displacements; but in considering the uses and limitations of pessaries it is at least permissible to indicate that there is a more excellent way than theirs. Thus, most cases of prolapse of the vaginal walls can be improved or cured by perineorrhaphy and other plastic operations; and abdominal surgery provides many procedures for the definite cure of prolapse and backward displacements. Experience leads me without reserve to profess myself one of those who would fain see the use of pessaries restricted to the irreducible minimum by the substitution for them of operative measures, which do all, and more than all, that pessaries can do—without their manifold drawbacks and risks.

## THE COMPARATIVE ADVANTAGES OF INORGANIC AND OF ORGANIC IRON IN THE TREATMENT OF ANÆMIA.

By WILLIAM MURRELL, M.D., F., R.C.P.,

Physician to the Westminster Hospital; Lecturer on Clinical Medicine, and Joint Lecturer on Medicine in the Westminster Hospital Medical School.

MUCH difference of opinion exists among therapeutists as to the comparative advantages of inorganic and of organic iron in the treatment of anæmia, and in this country few attempts have been made to investigate the subject scientifically. It is perhaps hardly a matter for surprise, for clinical hæmatology is still in its infancy, and experiments of this kind are liable to many sources of error. Ringer and Sainsbury point out that in some cases the astringent preparations are unsuitable, but that in most cases they produce better results than the Bland preparations of iron. This statement in a slightly modified form has appeared in many successive editions of "Ringer's Therapeutics," and it is practically certain that it is an impression derived from clinical observation and that it does not rest on the solid foundation of blood counts and estimations of hæmoglobin values.

Professor Ralph Stockman, of Glasgow, is equally positive in his advocacy of the superior value of the inorganic salts, but an examination of his admirable paper in the *British Medical Journal*, an article replete with most valuable information, shows that this was not one of the points which fell within the scope of his investigation. He records, it is true, some observations with Kobert's "hæmol" and "hæmogallol," which failed to give very encouraging results, but it is doubtful if these preparations have any claim to be regarded as true organic iron compounds or if they would respond to MacCallum's test. He proves conclusively that iron is the only drug of any value in the treatment of anæmia, but beyond that he does not go, and he records no comparative examination with different preparations of iron. Dr. C. D. F. Phillips, in the last edition of his "Inorganic Substances," is cautious in his expression of opinion, and says:—"The choice of a compound in any case of anæmia or chlorosis seems to me always to depend on the susceptibilities of the patient to the drug. Some are never able to take the astringent preparations even when the alimentary canal is not deranged." Iron, as far as we know, is the only drug of any value in the treatment of anæmia, and there is no reason to suppose that in this condition arsenic increases either the number of red blood corpuscles or the hæmoglobin value. Manganese in this connection is equally inert, and although I have prescribed it largely and in all forms, and with much success, for the relief of functional amenorrhœa in chlorotic girls, I do not believe that it

exerts the slightest influence in removing anæmia or in improving the condition of the blood. The inutility of prescribing iron with either arsenic or manganese in anæmia is obvious, for iron alone answers the purpose admirably, and the addition of another drug is superfluous.

The generally accepted view is that all forms of iron are useful in anæmia, but that they differ much in their efficacy and in the rapidity of their action. The inorganic salts are more frequently prescribed in hospital practice, whilst for private patients the Bland and less irritating preparations are the favourites. The explanation of this is simple, for it is well known that the more robust hospital patient requires larger doses of most drugs, purgatives for example, than private patients, and that the latter are more readily inconvenienced by remedies which irritate the mucous membranes of the stomach and intestines. No mere expression of opinion, however, is of much value, and the only evidence on which reliance can be placed is that founded on comparative blood examinations. It is not every case of anæmia which lends itself to this investigation. Cases of pernicious anæmia are beyond the scope of the action of iron, and are, as a rule, but little benefited by it. Cases of parasitic anæmia, such as those due to the ankylostomum duodenale, are best treated by intestinal antiseptics, although iron is useful in a later stage. The anæmias due to toxæmia, such as lead poisoning, have their specific treatment, although here again, when the existing cause has been removed, the judicious administration of iron, especially in a Bland form, proves beneficial. Anæmia, following organic change, such as cancer of the liver secondary to a primary deposit in some other organ, runs a downward course, and is not arrested by the administration of any drug. Still, there are many forms of anæmia which readily lend themselves to investigations of this nature. The best examples are the secondary anæmias of hæmorrhage, such as we get in the hæmatemesis of gastric ulcer and the chlorosis of young women, which forms so large a part of our out-patient practice. But here again a difficulty is introduced, for out-patient work is not conducive to accuracy of observation and certainly not to scientific observation. A chlorotic patient on her first visit is submitted to a blood examination, and is given a prescription for some form of iron. A week later she comes again and there is an alteration, perhaps an improvement, in her blood count and in the percentage of hæmoglobin, but there is no proof that the medicine was taken with regularity or, for the matter of that, at all. The only cases really adapted for experimental observation are those seen in private practice or in the wards of a hospital, where the administration of every dose is checked and systematically reported. Even under the most favourable circumstances there are fallacies to be avoided. A chlorotic woman is taken into the hospital, she has the benefit of rest in bed, she is placed under favourable hygienic conditions, her bowels are regulated, and she is carefully dieted. These are disturbing elements. What influence have they on the anæmia, and will they alone effect a cure? Here is a case in point:—

CASE I.—A girl, æt. 21, was admitted on October 10th, 1901, suffering from anæmia of four months' duration. She complained of general weakness, shortness of breath, and palpitation on exertion and loss of appetite. Her red corpuscles numbered 3,100,000 per c.mm., and were normal in shape and size. The leucocytes were 9,200 and the hæmoglobin value was 50 per cent. She was kept in bed, placed on a liberal diet, and constipation was relieved, but no iron was given. On October 29th, the red corpuscles were 2,687,000, and the hæmoglobin value was 35 per cent. She was more anæmic than on admission, and had made no progress towards recovery. She was then given five grains of exsiccated sulphate of iron three times a day, increased a few days later to ten grains. On November 12th, the red corpuscles were 4,900,000, and hæmoglobin value was 60 per cent. The improvement was very marked, being at the rate of 158,000 and 1·8 per cent. a day. This case shows that the patient in no way

benefited by her nineteen days' expectant treatment, and that she improved with remarkable rapidity when iron was administered.

It seemed desirable to obtain some kind of standard as to the increment of erythrocytes and daily increase in hæmoglobin value with inorganic iron, and the following cases throw some light on the subject:—

CASE II.—A housemaid, æt. 23, was admitted on May 10th, 1901, suffering from anæmia and vomiting. The patient stated that she had been ill for four years, and that she had been obliged to give up her work in consequence. Her erythrocytes numbered 3,320,000, and the hæmoglobin value was 48 per cent. She was given five grains of exsiccated sulphate of iron. On May 21st, the erythrocytes were 4,300,000 and the hæmoglobin value was 63 per cent. The increase in the red cells was at the rate of 140,000 a day and the hæmoglobin a little over 2 per cent.

CASE III.—A girl, æt. 21, had suffered intermittently from anæmia since the age of 13. She had had much treatment and was for seven weeks an inmate of a convalescent home. On admission, her erythrocytes were 1,725,000, the hæmoglobin value being only 15 per cent. She was given dried sulphate of iron three times a day, and in eleven days the erythrocytes had risen to 2,970,000, and the hæmoglobin to 36 per cent. This was at the rate of 140,000 red cells and 1.9 per cent. hæmoglobin a day.

CASE IV.—A woman, æt. 44, had been suffering from shortness of breath and swelling of the ankles for some months, so that she was unable to follow her occupation. There was no cardiac mischief, and the urine was free from albumin. The erythrocytes numbered 2,225,000, and the hæmoglobin value was 54 per cent. On the sulphate of iron treatment the blood corpuscles rose in twenty-three days to 2,875,000, and the hæmoglobin value to 61 per cent. The increase in the number of red cells was at the rate of only 29,000 a day, and the hæmoglobin 0.3 a day.

CASE V.—A girl, æt. 21, a school teacher, was admitted complaining of dyspnoea and palpitation on exertion. She had suffered from anæmia with amenorrhœa for three years. She had never had rheumatic fever, but there was a soft apex systolic murmur, probably not organic in origin. Her red cells were 3,250,000 and the hæmoglobin value was 43 per cent. It was a typical case of oligocythæmia and oligochromæmia. She was given sulphate of iron, and at the expiration of eighteen days the red cells numbered 4,450,000, and the hæmoglobin value was 55 per cent. The average daily increase was 75,000 and 0.66 per cent.

Taking the average of these five cases treated with exsiccated sulphate of iron it will be seen that the daily increase of red blood corpuscles was 103,200 and of hæmoglobin value 1.33 per cent. I have notes of other cases, in some of which the results were less striking, and I am satisfied that in ordinary chlorosis treated with sulphate of iron a daily increase of 100,000 a day with 1.3 per cent. hæmoglobin is a liberal estimate.

I made a similar series of observations with tincture of perchloride of iron given three times a day in either fifteen or twenty minim doses, with the following daily improvement:—

Case.	Erythrocytes.	Hæmoglobin.
VI.	112,500	1.33
VII.	156,000	0.30
VIII.	82,000	0.55
IX.	50,000	0.54
X.	45,000	0.53

This gives a daily average increase of erythrocytes of 89,000, and of hæmoglobin value 0.65 per cent., which is less favourable than with sulphate of iron, especially with regard to hæmoglobin. Combining the results of the sulphate of iron and perchloride of iron cases it works out at 96,000 and 0.99 per cent., or, roughly, a daily increase of 100,000 erythrocytes and 1 per cent. hæmoglobin value. This may be taken as the inorganic iron standard under favourable circumstances.

Romberg, in cases of anæmia in which the red cells

were below 4,000,000, found that the daily increase under inorganic iron treatment was not more than 43,000 with 0.99 per cent. hæmoglobin. Probably our observations were made under somewhat different circumstances, and although we are in accord with respect to the hæmoglobin, his increment of red cells is below mine.

I have had a comparatively limited experience with Bland's pill, which I regard as inferior to the dried sulphate of iron pill. Thayer states that in severe cases of anæmia when the red cells were below 2,000,000 and the hæmoglobin value was under 20 per cent., ten grains of Bland's pill three times a day increased the red cells at the rate of 107,000 a day and the hæmoglobin value at the rate of 2.7 per cent. I cannot but regard this as a very high estimate. The average duration of the treatment was twenty-eight days, which is in excess of that usually required.

Turning now to organic iron. Several preparations have recently been introduced made from spinach growing on ferruginous soil. I have had some experience of one of these, a dark green fluid with a pungent aromatic taste, due probably to the addition of flavouring agents. It is not necessary to give details, but the results worked out at 70,000 a day for the red corpuscles, whilst the increase in hæmoglobin value was small. I have also notes of cases treated with a popular blood preparation, the result showing an improvement of 86,000 red corpuscles and 1.67 per cent. hæmoglobin a day.

Probably the best of the organic iron preparations is the iron-vitellin, discovered by Dr. A. C. Barnes, of Philadelphia. This is a definite chemical product which gives a negative reaction with MacCallum's test. It is a red solution, neutral in reaction and both odourless and tasteless. I have used it not only in anæmia but in various other conditions, and it has yielded excellent results. The first test was a severe one, for the patient was suffering from cancer of the stomach.

CASE XI.—A woman, æt. 39, was admitted on April 28th, with severe hæmatemesis, apparently due to gastric ulcer, the symptoms of which were of short duration. The erythrocytes numbered 2,180,000, the leucocytes 16,600, and the hæmoglobin value was 25 per cent. She was fed by the rectum and was given an aperient iron mixture three times a day. On May 12th, there was another profuse hæmorrhage, and on the 13th a smaller one. On the 14th, the erythrocytes were 2,900,000, the leucocytes 13,200, and the hæmoglobin value was 28 per cent. She was markedly cachectic and was losing flesh rapidly. Nodules were detected on the surface of the liver, evidently malignant, and probably due to a primary growth in the stomach. She was given iron-vitellin in half-ounce doses three times a day. There was no recurrence of the hæmorrhage. On May 25th, the erythrocytes were 2,280,000, the leucocytes 14,600, and the hæmoglobin value 24 per cent. On June 1st, the erythrocytes were 2,670,000, the leucocytes 12,200, and the hæmoglobin value 30 per cent. The patient died on June 14th, and the correctness of the diagnosis was confirmed at the autopsy. In a case of malignant disease running a downward course no marked improvement could have been expected from any drug, but there was no recurrence of the hæmorrhage and there was some increase in the percentage of hæmoglobin.

The following case was more successful and gave excellent results:—

CASE XII.—The patient was a housemaid, æt. 17, who had been suffering from chlorosis for six months, for which she had had much treatment without benefit. On June 2nd, her red corpuscles numbered 2,410,000, and her hæmoglobin value was 40 per cent. She was placed on iron-vitellin three times a day, and on June 8th, the red cells were 4,230,000, the hæmoglobin value being 42 per cent. She had menstruated during the time. The increase in red cells was at the rate of 303,000 a day, and hæmoglobin value 0.33 per cent. Although diminution in hæmoglobin value is the essential feature of chlorosis, there is, in many cases,

a decreased number of erythrocytes, and the red cells are small and irregular in shape.

The next are similar cases:—

CASE XIII.—A girl, *æt.* 23, complained of frontal headache, general weakness, and lassitude and dyspnoea on exertion. The bowels were obstinately confined and the catamenia had been absent for four months. The conjunctivæ, lips, and nails were pale, and the condition was obviously due to anæmia. She had taken Bland's pill in five-grain doses three times a day without any amelioration of the symptoms, but with increased constipation, the bowels acting only every four or five days. The accumulation of fæces was removed by the administration of five grains of calomel, after which she was given half-ounce doses of the iron solution three times a day. There was an immediate improvement in her general condition, and in three weeks her red cells increased from 2,850,000 to 4,782,000, being at the rate of 92,000 a day. The hæmoglobin value increased from 52 to 70 per cent., being at the rate of 0.85 per cent. a day.

CASE XIV.—The patient was a woman, *æt.* 26, whose blood was examined at intervals of four days for a fortnight. The initial count showed erythrocytes 2,260,000, with hæmoglobin value 56 per cent. At the second examination the red cells were 3,400,000, with hæmoglobin 62 per cent. Four days later they numbered 4,200,000, and the hæmoglobin value was 68 per cent. At the final examination at the expiration of fourteen days the red cells were 4,480,000, with hæmoglobin value 76 per cent. In this case the rise was at the rate of 158,000 a day and hæmoglobin 1.6 per cent. The iron solution was given in half-ounce doses three times a day.

The next case belongs to a different category:—

CASE XV.—A governess, *æt.* 30, suffered from anæmia, the result of a prolonged attack of rheumatic fever with mitral regurgitation. She was breathless and incapable of much exertion. Her erythrocytes numbered 3,450,000, and her hæmoglobin value was 43 per cent. She was given iron-vitellin for ten days, and at the expiration of that period the red cells were 4,500,000, with hæmoglobin 62 per cent. Her subjective symptoms had disappeared, her appetite had improved, and she was able to take a fair amount of exercise. The erythrocytes had increased at the rate of 105,000 a day, and the hæmoglobin value 1.9 per cent. a day. The iron-vitellin in this and other cases apparently exerted a general tonic action quite apart from its influence on the blood constituents. In two cases in which, although the patients were markedly debilitated, the erythrocytes numbered over 6,000,000, an improvement in tone and in the general condition of the health followed its administration. It seems to be useful in those anomalous cases of anæmia such as are met with in children in which diminution in the number of red cells, and even of hæmoglobin value, is not the predominant factor.

The next was a case of secondary anæmia:—

CASE XVI.—A woman, *æt.* 28, was anæmic as the result of a profuse hæmatemesis due to gastric ulcer. For some weeks she had complained of pain referred to the pyloric end of the stomach following each meal. There was only one attack of bleeding, and it was difficult to estimate the amount, although apparently it was profuse. The family history was not good, the mother having died of malignant disease of the uterus. On the day following the hæmatemesis the erythrocytes numbered 3,260,000, the white cells were 6,500, and the hæmoglobin value was 50 per cent. The patient was kept in bed in a recumbent position and was given three pints of milk in the twenty-four hours. The bowels were kept well open, and half an ounce of the iron solution was ordered three times a day. There was no return of the bleeding, and at the expiration of ten days solid food was taken without difficulty. The erythrocytes then numbered 4,460,000, the white cells were 7,500, and the hæmoglobin value was 70 per cent. The daily increase of red cells was 120,000 a day with 2 per cent. hæmoglobin.

The last case belongs to a type which is by no means uncommon:—

CASE XVII.—A man, *æt.* 53, complained of want of energy and general weakness with shortness of breath on exertion, especially on going upstairs. For many years he had led an active life mentally, but had taken very little physical exercise, rarely walking more than half a mile a day. He was a free liver, and took three good meals a day with a plentiful allowance of alcohol at lunch and dinner, usually in the form of champagne, with an occasional glass of port and whisky in the evening. He had put on flesh, but his muscles were flabby and the superficial veins of the face and nose were enlarged and congested. He was emphysematous and suffered from a chronic cough, kept up by incessant smoking. He was in a nervous and irritable condition, and slept badly. His arteries were hard and the heart was dilated, although there was no murmur. The liver was enlarged, and there was a trace of albumin in the urine. The bowels were confined, but were relieved from time to time by large doses of an aperient bitter water. His red corpuscles numbered 2,750,000, and the hæmoglobin value was 38 per cent. He was kept in bed, his alcohol was knocked off, and he was given three pints of milk and a pint of beef-tea a day. The bowels were kept freely open with sulphate of magnesium, and an ounce of iron-vitellin was given three times a day. At the expiration of ten days he had materially improved, the albumin had disappeared from the urine, his tongue was clean, he slept better, and expressed a strong desire for food. His erythrocytes had increased to 4,400,000, the leucocytes had fallen to 9,500, and the hæmoglobin was 47 per cent. The daily increase in the erythrocytes was 165,000, and hæmoglobin value 0.9 per cent.

Excluding the first of these cases, which was obviously unsuited for treatment, we find that under the iron-vitellin treatment the daily increase in erythrocytes was 157,000, and the hæmoglobin percentage 1.26. This, with regard to the red blood corpuscles, shows an improvement of 50 per cent. over the best inorganic iron treatment, and with regard to the hæmoglobin value a gain of 25 per cent.

These observations are admittedly incomplete and merely touch the fringe of the subject, but they show that a good organic iron preparation compares favourably with the best of the inorganic salts apart from the great advantage of being easily assimilated and free from the discomforts which so frequently attend the administration of the astringent forms of the drug.

### ABSTRACT OF The Cavendish Lecture

ON  
EXPERIMENTS ON THE IMMUNISATION  
AGAINST INFECTION OF OPERATION  
WOUNDS, ESPECIALLY OF THE  
PERITONEUM. (a)

By JOHANN VON MIKULICZ-RADECKI, M.D.,  
LL.D.,

Professor of Surgery in the University of Breslau.

MR. PRESIDENT AND GENTLEMEN,—The successful treatment of infectious diseases to-day involves in many cases a combination of the two methods of treatment discovered, the one by Edward Jenner and the other by Lord Lister. Hygienic measures based upon Listerian principles attempt to exclude or render harmless the cause of infection, whilst specific preventive inoculation endeavours to render individuals more capable of resisting infection. Surgery has made but little use of the principle of preventive inoculation because the multitude of pyogenic micro-organisms which may infect the wound adds greatly to the difficulty of finding a practical method of inoculating against them. The immunisation of wounds does not press with the urgency of general infectious diseases because

(a) Delivered before the West London Medico-Chirurgical Society June 24th, 1904.

the majority of wounds are efficiently guarded from infection by antiseptic treatment. There are, however, many operations in which the principle of antiseptics becomes useless because the affected tissues or organs, owing to their physiological properties or their pathological conditions, are invaded by pathogenic organisms. The problem of effectually disinfecting the mucous membrane of the stomach and intestines in preparation for operation has not yet been solved. We possess, it is true, a number of technical expedients for limiting the danger of infection, but they do not succeed with certainty in preventing it in every case. The dangerous peritonitis in serious operations on the stomach and intestines is due to the fact that the bacilli from the intestines escape in too great a number to be tolerated by the peritoneum; that is to say, the natural power of resistance of the peritoneum in the individual is not sufficient to overpower the mass of bacteria introduced. We can diminish the danger of peritonitis at the present time only by increasing the power of resistance of the peritoneum against intestinal bacteria. One means of effecting this is by producing an artificial hyperleucocytosis. Loewy and Richter were the first to try by the injection of albumoses, especially spermin, into animals to produce a hyperleucocytosis and thereby to make the animals capable of resisting infection of pneumococci. In a similar way Jakob, by intravenous and subcutaneous injection of albumose into rabbits, made them proof against pneumococci and mouse septicæmia. After each injection a hyperleucocytosis occurred first and later a hyperleucocytosis. If the infection was brought about during hyperleucocytosis the animals without exception died. On the other hand, the course of the disease was influenced in the most favourable way when the infection was introduced after a hyperleucocytosis had occurred, and was still increasing. Hahn succeeded in showing that during that stage of hyperleucocytosis the blood of men and dogs possessed a higher bactericidal value than normal blood. Hahn used yeast nuclein in his experiments on dogs and tuberculin in those on man. These experiments do not seem to have led to any practical result in the case of man. At any rate, Goldscheider did not entertain great hopes of the therapeutic value of hyperleucocytosis. More recently Hofbauer, in Vienna, has obtained favourable results in undoubted puerperal septicæmia by the administration of from five to six grammes of nuclein by the mouth. The slight therapeutic value of artificial hyperleucocytosis in disease which has already made itself evident—as, for example, in pneumonia—can be readily understood. The infected organism is at the time of the application of the remedy overpowered by the pathogenic microbes; all the engines of defence of the organism have already had to be led into the field. A still further increase through a later artificial hyperleucocytosis cannot be expected.

The question arises whether artificial hyperleucocytosis may not be of value in practice as a prophylactic. According to the above-mentioned experiments one cannot exclude the possibility that by a partly anticipated mobilisation of great masses of leucocytes the latter may overcome the bacteria which have obtained entrance in the first instance in relatively small masses with greater ease than if the leucocytes delay their attack in force until the number and virulence of the bacteria in the tissues have markedly increased. Whether the observations of Jakob are applicable to the peritoneum had to be established by experiments on animals before they could be used upon man. Dr. Miyake, of Japan, who recently worked in my clinic, undertook at my suggestion these experiments upon animals. These were carried out in the Breslau Hygienic Institute under the control of Professor Flügge. We already had a predecessor named Salieri, who, in 1902, carried out experiments to increase the resistance of the peritoneum against bacillus coli infection, and found that with small quantities of normal saline solution he could increase the natural resistance in guinea-pigs by sevenfold to sixteen-fold. The experiment was made three times on man in cases of

laparotomy in which Salieri injected from 30 to 60 cubic centimetres of saline solution into the abdominal cavity. Salieri believed that he obtained favourable results, but in my opinion the operations carried out by him do not definitely demonstrate an increased resistance of the peritoneum. Salieri was led to undertake his investigation by the well-known experiments against cholera conducted by Issaëff, in 1894. Issaëff produced in guinea-pigs hyperleucocytosis in the peritoneal transudate by intraperitoneal injections of normal saline solution, of bouillon, of nucleic acid, and of tuberculin. At the summit of this hyperleucocytosis he injected virulent cholera vibrios into the peritoneum and noted, according to the nature of the injected fluid, a more or less marked increase in the resistance of the peritoneum to the injected cholera bacilli. The most powerful reaction was obtained with nucleic acid. With an injection of one cubic centimetre of a 2 per cent. solution of nucleic acid the peritoneum was able to withstand from 13 to 17 lethal doses of cholera vibrios. Issaëff observed that the destruction of the microbes was carried out by the leucocytes of the peritoneal transudate. After only two hours the phagocytosis was evident. In the third hour free micro-organisms could no longer be found in the exudate and after five hours the process of destruction of microbes was completed. Just as Issaëff used guinea-pigs for his experiments, we, too, selected that animal. Although the prospects of a satisfactory specific active immunisation of man against the virus of peritonitis, as has been explained, are extremely small, nevertheless we made experiments in this direction first, for in guinea-pigs the conditions are much more favourable. The bacilli coli alone are markedly pathogenic for the peritoneum of the guinea-pig, whilst the other co-excitors of peritonitis in man, especially the streptococcus and staphylococcus pyogenes, are almost entirely harmless to guinea-pigs. The experiments were carried out in this way. From half a loopful to two loopfuls of a sterilised culture was injected into the peritoneum from a strain of bacillus coli. After a definite interval, which was different in different experiments, had elapsed, the animals tolerated the introduction of five loopfuls of living virulent culture and also the escape of the contents of the intestine into the abdominal cavity. The active immunisation with a strain of bacillus coli (derived from man) was thus, we may presume, able to protect against other bacillus coli strains that were accidentally present in the contents of the intestine. Nevertheless, it is possible to come across by chance strains in the case of which this does not occur. That in man we have to reckon not only with different strains of bacilli coli, but also with different strains of streptococci and other pathogenic bacteria, has been demonstrated above. On these grounds we did not make any further experiments for obtaining a specific active immunisation even of guinea-pigs. The further experiments consisted exclusively in producing a general increase in resistance by hyperleucocytosis. In accordance with the procedure of Issaëff we tried the injection of various fluids into the peritoneal cavity; later, subcutaneous injections were also tried, for this form of application is better adapted to man than that of intraperitoneal injections. Sodium chloride solution (0.85 per cent.), neutral bouillon (2 per cent.), starch in physiological salt solution, and nucleic acid were used for injection. The first three solutions were only used intraperitoneally, nucleic acid subcutaneously as well. For intraperitoneal injection 2 per cent. of nucleic acid was used, for subcutaneous injection 5 per cent. neutralised nucleic acid solution; one cubic centimetre of the solution was injected per 250.330 grammes bodyweight. We found, in agreement with earlier experimenters, that the intraperitoneal injections of normal saline solution in the quantities above mentioned gave rise to a marked hyperleucocytosis in the peritoneal transudate. The maximum was reached after from 17 to 18 hours with an increase to about fourfold the normal leucocytosis. Still greater was the effect when the peritoneal cavity was washed out with 50 cubic

centimetres of normal saline solution; in this case about two-thirds of the solution was left in the cavity. Maximum hyperleucocytosis occurred after 24 hours and resulted in five times the normal number of leucocytes. The reaction due to neutral bouillon was much less marked than that of normal saline solution. But a far more energetic action followed the 2 per cent. aleuronat mucilage. The maximum peritoneal hyperleucocytosis occurred in 30 hours and rose to between seven and eight times the normal number. A similar result followed the use of nucleic acid, but the reaction was more speedy. The maximum was between seven and eight times the normal, and occurred eight hours after the injection. Along with the local, general leucocytosis in the blood took place but to nothing like the same extent. The maximum in one case was double the normal number of white cells. Subcutaneous injection also of 5 per cent. nucleic acid led to a hyperleucocytosis in the peritoneum, as well as in the blood. The latter reached almost to the same height as with the injection in the peritoneum, the former remained far below. It reached approximately two and a half times the normal number. The important point is that here also, as in the experiments of Jakob, the injection caused a hypoleucocytosis in all cases after half an hour to one and a half hour. With normal saline solution and with bouillon it was not considerable; with aleuronat and nuclein it fell even to one-tenth of its original amount in the peritoneal transudate. No general disturbance of any importance occurred. With the injection of normal saline solution the temperature was scarcely raised; with aleuronat and nucleic acid there was a rise of from  $0.5^{\circ}$  to  $1.5^{\circ}$  during the first hours after the injection.

After these experiments we used the injection with the above-mentioned fluids as a preliminary to an infection of the peritoneum, and in the first instance a strain of bacterium coli was employed, which we found to be very virulent for guinea-pigs. After it had been ascertained by eleven test experiments that the minimum lethal dose was a quarter of a loopful, the prepared animals were infected with the same strain. The infection of the peritoneum followed regularly seven hours after the preparatory treatment, and therefore at a time when the hyperleucocytosis had not yet quite reached the maximum. The result was as follows:—The effect of a single injection into the peritoneum of one cubic centimetre of normal saline solution was relatively weak, the power of resistance being only doubled (the infection after washing out the peritoneum with saline solution could not be employed because the bacillus coli strain at the time of the experiments in question had already lost its virulence). Much more energetic was the action of the intraperitoneal injection of aleuronat, since it increased the resistance of the peritoneum eightfold. Nucleic acid was still more active, for with this the power of resistance of the peritoneum was raised from sixteen to twenty-fold. The subcutaneous injections of 0.5 per cent. neutralised nucleic acid similarly increased the power of resistance of the peritoneum from sixteen to twenty-fold. Distinctly weaker was the action of a 0.25 per cent. solution. The effect of repeated intraperitoneal injections of nucleic acid was considerably stronger. In this manner the resistance of the peritoneum could be raised to forty times the normal. Repeated subcutaneous injections of nucleic acid led to 32 times the normal resistance. I may note in passing that none of the fluids used for injections in the neutralised form had any bactericidal action upon the bacterium coli selected for injection. It would have been very desirable to carry out the same series of experiments against the other bacteria that collaborate in the production of peritonitis in man, and, above all, against the streptococcus and staphylococcus aureus and albus. Unfortunately, we found, in agreement with other people's observations, that the streptococci and staphylococci isolated from patients in our clinic were non-virulent for guinea-pigs. We therefore tried experiments upon rabbits, but the same difficulty arose. It is not easy to find a strain of

staphylococci which has a pathogenic effect on the peritoneum of the rabbit. We can definitely assume from the experiments of Kiskalt that in combating the staphylococcus pyogenes both leucocytosis and the destruction of the bacteria by the method of phagocytosis play at least as important a part as when the fight is between the organism and the bacterium coli. So far as the streptococcus is concerned the strains isolated from our clinic were insufficiently virulent for the peritoneum of the rabbit. One of the strains of the streptococcus given to us by Dr. Aronson, of Berlin, was, it is true, virulent for rabbits, but to such a great extent that it acted as a specific bacterium of these animals. Against these highly virulent specific bacteria little effect is, as we already know, produced by a general increase of resistance by hyperleucocytosis. In these cases only a specific immunisation is of avail against infection. For these reasons the experiments could not be carried out in the way referred to. On the other hand, the experiments upon bacilli coli were supplemented in a most satisfactory manner by a series of observations which simulated the natural conditions occurring in peritonitis due to perforation. The experiments consisted in performing a laparotomy and forcing through an opening in the stomach or intestine as much of their contents as could be obtained from the immediate neighbourhood of the incision. Of five control animals which had not been previously prepared four died from peritonitis between five and sixteen hours after the operation. The fifth became extremely ill but finally recovered, but the amount of intestinal contents which was transferred to the peritoneum was less in this case than in the others. Ten animals were prepared. These recovered without exception. The preparation consisted in three intraperitoneal injections of nucleic acid, two injections of sterilised bacteria coli, three more injections of nucleic acid into the peritoneum, and two subcutaneous injections of neutralised nucleic acid. In each case laparotomy was performed seven hours after the injection. These experiments are such as to excite our interest in the highest degree, for by subcutaneous injections of nucleic acid it was possible to raise the resistance of the peritoneum to such an extent that even a considerable quantity of intestinal contents could be placed in the peritoneal cavity without causing damage, whilst without previous treatment an acute, rapidly fatal peritonitis followed almost without exception. This opens out a new field for the surgeon in preventing post-operative peritonitis. On three more animals a therapeutic experiment with neutralised 2 per cent. nucleic acid was tried. This solution was injected subcutaneously some time after the injection of the peritoneum with bacilli coli. It was found that when the infection had preceded the injection by six hours the peritoneum was able to stand only four times the lethal dose; whilst if the infection had taken place only one and a half hour before, then the animal was able to withstand eight times the lethal dose. One animal which received twelve times the fatal dose along with the nucleic acid injection succumbed nineteen hours after the infection. It therefore follows that subcutaneous injection of nucleic acid, if not used at too great an interval after the peritoneal infection, possesses a definite therapeutic value. This observation may perhaps be of value in acute cases of peritonitis from perforation.

I felt justified after these promising experiments upon animals in beginning similar experiments, safeguarded by every precaution, upon man. We first tried a  $\frac{1}{2}$  per cent. solution of the neutralised nucleic acid, and gradually increased the strength up to 4 per cent. As a rule, 50 cubic centimetres of the solution were injected subcutaneously. Intraperitoneal injection was tried in one case; and that the very first, but this method was entirely relinquished owing to its difficulty and the trouble it gave the patient. The 4 per cent. solution was injected twice. Thenceforth we always used the 2 per cent. solution, so that an adult man received about one gramme of nucleic acid to 75 kilogrammes of bodyweight. In all, 58 cases were treated in this

way. In 55 cases the operations were upon the stomach, intestine, or other abdominal viscera, and in three cases for extra-abdominal disease. In four cases the operations did not take place until more than 34 hours after the injection was given. We have thus on four occasions had the opportunity of observing the effect of the injection by itself. After the subcutaneous injection of neutralised nucleic acid we have constantly observed, not only in animals but also in man, a hyperleucocytosis in the blood which was almost always preceded during the first hour or so by a hypoleucocytosis. The question how high a degree of hyperleucocytosis was obtained through the injection is difficult to answer on the basis of our observations. We are not in a position to make any definite statements as to the beginning of the most favourable phase of hyperleucocytosis because the operation was, in the great majority of cases, apparently performed before the commencement of this phase. Only in five cases was there a distinct fall in the hyperleucocytosis before the operation; in one of these it occurred between 13 and 19 hours after the injections. The operations were performed in four cases from five to six hours, in nine cases from nine to twelve hours, and in twelve cases from 13 to 19 hours after the injections. The experiments on guinea-pigs showed that the optimum for nucleic acid was reached seven hours after the injection. It seems to occur in man considerably later. We have therefore recently fixed the interval between preventive injection and operation at 12 hours. We believe that we thus, as a rule, follow out the instructions to operate on the rising tide of leucocytosis.

As regards the phenomena accompanying the injection of nucleic acid, no serious local or general symptoms have as yet come under our observation. In the two cases in which a 4 per cent. solution had been injected the sensation of giddiness lasted but a short time. The most unpleasant factor for the patient is the local reaction. A tenderness and a slight swelling around the point of injection remain, as a rule, throughout the day. An intense erysipelas-like redness in two cases was seen, and it disappeared without leaving any trace after 24 hours. The only sign of reaction which appears with regularity is a slight increase in the temperature, which may be observed during the first few hours after injection ( $99^{\circ}$  to  $100^{\circ}$ ). In five cases the temperature remained below  $98.6^{\circ}$ , in 27 cases it rose to  $100^{\circ}$ , in six cases to  $101^{\circ}$ , in three cases to  $102^{\circ}$ , and in three cases above  $102^{\circ}$ .

You will now ask me how far the immediate object of the injection of nucleic acid was attained, and how far the preparation of the cases had a favourable effect upon the course of the operation. In ten cases of resection of the stomach for carcinoma nine recovered, six of them without the slightest complication. The progress was marked by a smoothness that was quite exceptional before this treatment was adopted. Two cases which presented exceptional difficulty in the removal of the carcinoma did undoubtedly within 24 hours develop peritonitis with a pulse up to 160, which according to our usual experience foretold the most dismal prognosis. The patients fortunately survived this peritonitis. In the ninth case which recovered the progress was disturbed from the fourth day by broncho-pneumonia. The tenth case died; after seven days of uninterrupted progress he developed pneumonia, to which he succumbed three weeks after the operation. Of the remaining operations I should like to refer first to 22 cases of gastro-enterostomy and entero-anastomosis, 12 of which were for carcinoma. Of these cases 19 recovered and three died. In all three cases death was most certainly not due to post-operative peritonitis, but in one case to perforation of an ulcerated carcinoma of the stomach two weeks after the operation, in another case to continued hæmorrhage from a carcinoma of the stomach 16 days after the operation, and in the third to peritonitis arising from a tuberculous granuloma in the intestine four weeks after operation. Of six cases of resection of the intestines at one operation four recovered and

two died. In one case death occurred from collapse on the second day after a very prolonged operation of double resection for carcinoma; in the other case, where the injury was a bullet wound, death took place on the tenth day from hæmorrhage from the vena cava. In neither of the cases was there any peritonitis. One case of opening the stomach and stretching the cardiac orifice, performed on account of spasm, recovered. So also did six cases of operation on the bile-duct, seven other operations upon abdominal organs without opening the intestinal tract, and three extra-abdominal operations. The last to be mentioned are two cases of nephrectomy which were treated before the operation with nucleic acid. In both cases in order to remove the suppurating kidney the peritoneum had to be widely opened. One case recovered; the other died 12 days after the operation from hæmorrhage from the renal artery. In this case, too, there was no peritonitis. We therefore have 45 laparotomies in which the abdominal cavity was exposed to infection by the contents of the stomach or intestines or by some other infectious secretion. Of these cases 38 recovered and in none of the seven fatal results was peritonitis the cause of death.

While relating my clinical experiences, I have referred to nucleic acid only as a method of producing leucocytosis, but we have also used in most cases, and especially in severe operations upon the stomach and intestines, a second means which, according to experimental observations, is able to increase considerably the power of resistance of the peritoneum—I mean the intraperitoneal infusion of normal saline solution. Departing from my earlier practice I have used more and more during the last two years free irrigation of the peritoneal cavity with warm normal saline solution in all laparotomies in which the peritoneum runs some risk of infection.

## Transactions of Societies.

### SOCIETY FOR THE STUDY OF DISEASE IN CHILDREN.

MEETING HELD FRIDAY, MAY 27TH, 1904.

MR. WALTER EDMUNDS, F.R.C.S., in the Chair.

*A Case of Multiple Sarcomata of the Scalp* in a child, æt. 2, was shown by Mr. WILSON for Dr. EDMUND CAUTLEY. In September, 1903, the right eye had been excised for glioma. One month previously lumps had been noticed on the head, which had grown rapidly. At present the new growths were numerous, large, and scattered over the scalp. There was also evidence of involvement of the left eye, and a purple discoloration of the eyelids on both sides was present. The face was of a waxy pallor and œdematous.

Mr. GEORGE PERNET described a case of multiple sarcomatous growths in the skin in which the right eye was bulged forward, presumably from a primary growth behind it.

*A Case of Tumour Occupying the Left Half of the Abdomen*, in a girl, æt. 6, was shown by Mr. FRANCIS JAFFREY. She had suffered from pain in the left side of the abdomen, hæmaturia, and difficulty in micturition. The tumour was smooth and elastic, did not fluctuate, and was fairly movable. He was of opinion that it was a case of sarcoma of the left kidney, and asked as to the advisability of operative treatment.

Mr. WATSON CHEYNE agreed with the diagnosis, but thought that complete removal could not be looked for, as the pedicle of the kidney seemed to be involved.

Mr. CLEMENT LUCAS thought that, as the case was probably hopeless if left alone, an effort might be made to remove the tumour if possible.

The CHAIRMAN (Mr. Walter Edmunds) thought that an exploratory incision might be employed to determine whether the tumour was removable or not. He asked for particulars as to history of such cases after operation.

Mr. THOMSON WALKER said that an increasing

number of renal tumours were removed from children with immediate good results, and with a good after-history, namely, of three to five years in which no recurrence had taken place. Each case must be taken on its own merits, and if the tumour were examined from within the abdomen there would be a better chance of ascertaining whether it was removable, and whether there was likely to be a recurrence.

*A Case of Status Lymphaticus* was described by Mr. HUNTER TOD. An infant, *æt.* 6 months, had been the subject of laryngeal stridor and died suddenly. Dr. WALTER EMERY showed the organs from this and another infant affected with the status lymphaticus. There was an enlargement of practically all the lymphoid tissues of the body, including the thymus, the glands (especially the mesenteric), the solitary follicles and Peyer's patches in the intestine, the tonsils, and the adenoid tissue of the naso-pharynx. The spleen and tongue were normal, the latter not showing enlargement of the circumvallate papillæ, which had sometimes been described as of diagnostic value. The thymus gland weighed almost exactly an ounce in each case, but there was no evidence of direct pressure on the vagus, the trachea, or the heart. He drew special attention to the marked thickening in parts of the intestinal wall from the overgrowth of lymphoid tissue.

Dr. E. P. BAUMANN confirmed this observation. He had seen two fatal cases, one an infant, *æt.* 3 months, and the other *æt.* 9 months. The first infant was brought to the hospital in a state of great respiratory embarrassment, cyanosed, and uttering peculiar respiratory sobs. Death soon ensued, and the thymus was found to weigh four and a half ounces. It lay chiefly on the right side, pressing on the heart, and it might also have pressed on the trachea, causing death directly from suffocation.

Mr. THOMSON WALKER said this was a very important subject, not only from the medico-legal point of view, but also from the surgical. One writer had collected ten cases in which death had occurred, at the commencement of chloroform administration, or during it, or immediately after the operation. In addition to the other changes mentioned, a hyperplasia of the arteries had been noted, leading to narrowing of the lumen.

Dr. EMERY, in reply, said that one could not absolutely exclude pressure on the trachea from the post-mortem findings. The thymus might suddenly become engorged with blood and exert direct pressure on the trachea, and all signs of this might have passed off before the post-mortem examination.

*A Case of Tuberculous Periostitis* was shown by Mr. LOCKHART MUMMERY. There was a fluctuating swelling on the middle finger of the right hand, and the right radius and right cheek were also the seats of tuberculous growths.

*A Case of Paralysis of the Left Trapezius Muscle following an Attack of Herpes* was shown by the CHAIRMAN (Mr. Walter Edmunds). The patient was a girl, *æt.* 6, who, three weeks after an attack of herpes affecting the skin over the left shoulder and the upper part of the left scapula, was found to have "winging" of the left scapula. This was found to be due to weakness of the left trapezius muscle, which responded neither to galvanism nor faradism.

*A Case of Achondroplasia*, in a boy, *æt.* 12, was demonstrated by Mr. HAROLD BALME. As usual in this affection the membrane bones were unaffected, while all the long bones showed marked shortening.

Mr. A. D. REID showed a series of skiagrams of this patient, with the following abnormal features: (1) The ends of the diaphyses were expanded; (2) both humeri were bowed; (3) there was a lateral curve in the left tibia and fibula; (4) the ends of the diaphyses of the long bones were notched; and (5) the phalanges were short and broad.

*A Case of Tuberculous Disease of the Elbow-Joint, with Dislocation of the Upper End of the Radius*, in an infant, *æt.* 15 months, was shown by Mr. J. THOMSON WALKER. Three months after a fall the elbow had become swollen

and tender, and the child was treated at another hospital for fracture about the elbow, the arm being put up in splints, and later massage was used. Under this treatment the arm got steadily worse. Mr. Thomson Walker found the ends of the humerus, radius, and ulna to be markedly thickened, and the joint swollen. There was also thickening of the fifth metacarpal bone of the left hand. As regards the diagnosis, he had to consider whether a fracture had ever been present, and whether syphilis might not be a factor in the case, as there was a history of numerous miscarriages. Under mercurial inunction and splinting the condition had almost entirely cleared up after four months. The patient then passed from observation, and some months later the joint was found to be much worse, and the upper end of the radius was dislocated forwards. Later there was definite evidence of tuberculosis in the joint.

*A Girl, æt. 2, with Motor Paraplegia and with Absence of Speech, which might have been Congenital, or Syphilitic, or Secondary to Scarlet Fever and Diphtheria*, was exhibited for diagnosis by Dr. EWART. He demonstrated a method of using the reflexes (superficial and deep) as a means of exercising paralysed muscles, which he had not previously published.

A paper on *A Case of Perforated Gastric Ulcer* in a boy, *æt.* 13, was read by Mr. WATSON CHEYNE and Dr. R. H. W. WILBE. The patient had enjoyed good health until the onset of the illness, which was marked by severe abdominal pain about the umbilicus. He rapidly became worse, and after consultation the same evening it was decided to operate. The appendix was examined, found to be diseased, although not actively, and was removed. As the signs pointed to some rupture, the rest of the abdomen was explored, and over the front of the stomach some turbid fluid was found, and gas bubbled up. On further searching, a small, round perforation was found on the anterior surface of the stomach about an inch from the cardiac end, from which gastric juice and gas were escaping. The ulcer was treated in the usual way, and the boy made an uninterrupted recovery. They referred to the rarity of perforating gastric ulcer, apart from tuberculosis, at this age. Another point of interest was that a diseased appendix was found and removed, but the presence of gas in the abdomen showed that there must be some other lesion. Unless this sign had been regarded as conclusive they would not have discovered the ulcer, for its situation was so remote that every part of the intestines and stomach had been previously examined, and very careful searching was required to find it.

Mr. CLEMENT LUCAS was not quite sure from the history of the case that tuberculosis could be excluded as the cause of the ulcer. The condition was certainly a very rare one.

Dr. PORTER PARKINSON referred to a case he had met with in a child of two years, where death was due to a perforating gastric ulcer, and where post-mortem no trace of tuberculosis could be detected in any part of the body.

## Special Articles.

BRITISH SANATORIA FOR CONSUMPTION.—  
XLIII.

[BY OUR SPECIAL MEDICAL COMMISSIONER.]

THE DARTMOOR SANATORIUM, CHAGFORD,  
DEVON.

DEVON'S famous highlands, Dartmoor, has long been a favourite resort of the artist and the antiquary, and a happy hunting ground for the sportsman, but its possibilities as a health station have received but little serious study. Various well-known resorts in Devon have been widely advocated and extensively used as residences for the consumptive, but it is a somewhat remarkable fact that at present there are only three sanatoria, one public and two private,

where efficient and systematic open-air treatment is provided in accordance with modern procedure. Dartmoor, particularly in the neighbourhood of its marginal fringe, offers climatic and geographical conditions peculiarly suited to the needs of many phthisical cases; and Chagford, on its eastern border, furnishes a locality almost ideal for the hygienic management of many patients with pulmonary tuberculosis. Dr. A. Scott Smith has, therefore, shown wise discernment in establishing his Dartmoor Sanatorium at Torr House, on the eastern slopes of Devon's tableland, at an elevation of about 750 feet above sea level, and about a mile and a half above and to the west of the charming hamlet of Chagford, 19.3 miles distant from London, and situated at an altitude of 650 ft. We have thoroughly explored the district and have carefully inspected the sanatorium, and have had the privilege of a personal study of the manner and method of management there employed, and are thus able to testify not only to the local advantages of the district, but can also bear witness to the very efficient and scientific conduct of the treatment.

Dr. Scott Smith is himself an old tuberculous patient who has had wide experience of sanatorium management. He is an ardent disciple of Walther, and his establishment is conducted on strict Nordrach lines, but softened by a sympathy which is characteristic of the best in English medicine, and strengthened by a sound common sense which must appeal to all unfortunate Britishers fortunate enough to come under Dr. Scott Smith's firm and far-seeing control.

The sanatorium is particularly well placed, sheltered by hills and trees from trying winds, freely open to the south and immediately surrounded by attractive grounds. The institution has been fitted for its purpose by a wise adaptation and modification of a large and well-constructed private country house. The patients' rooms have been furnished in accordance with modern demands. The dining-room is a large, airy and well-lit apartment. The house is provided with electric light; the drainage system is excellent, and there is a plentiful supply of water both for baths and drinking purposes.

At the present time the establishment is being enlarged by the addition of several admirably designed rooms.

Dr. Scott Smith, as we have had ample opportunities of observing, devotes himself entirely to the direction of his sanatorium. Every case is constantly under his supervision, and each detail of the patient's life is subjected to medical direction. Great care is given to the nutrition of the sufferers, and hyper-alimentation is rigorously enforced. The amount of exercise and rest is carefully regulated. The walks are peculiarly attractive, numerous, and in gradient, degree of protection and exposure allow of great variation. We consider the sanatorium almost unique among English institutions in the excellence of its facilities for picturesque and suitable pedestrian exercise. Other forms of exercise are wisely discouraged, and patients are not advised to spend time in shelters. They are thoroughly instructed in the hygienic management of their disease. The fear of chills from exposure or the dangers supposed to arise from getting wet are demonstrated to be in great measure mythical. No systematic medication is employed.

The sanatorium is placed in a truly romantic neighbourhood, embracing some of the finest river, mountain and moorland scenery in England. Opportunities for hill-climbing lie close at hand, and tors ranging from 800 to 1,400 feet are within easy reach. Patients with artistic tastes will find endless material for brush or pencil in the perfect river peeps on the South Teign, along the banks of which suitable cases can freely ramble. We consider the psychical influence of the district to be one peculiarly advantageous to phthisical patients of refined tastes and artistic inclinations.

It should be added that Dr. Scott Smith and his wife take all their meals with the patients, and lead the same open-air life. The maintenance of English

home life is an element the advantage of which patients are not slow to appreciate.

The terms depending on the room occupied are from three to five guineas per week, inclusive of medical attendance, board and lodging.

The sanatorium is by no means so inaccessible as might be thought. A carriage can be sent to meet patients on arrival at either of the two available railway stations, *viz.*, Moretonhampstead (G.W.R.), five miles off, or Okehampton (L. & S.W.R.), eleven miles distant.

Moretonhampstead can be reached from London *via* Exeter and Newton Abbott in about five and a half hours; and Okehampton *via* Exeter in about four and a half hours. During the summer months, by leaving Waterloo at 11 a.m. Okehampton may be reached at 3.12 p.m.

Omnibuses under the direction of G.W.R. run from Moretonhampstead to Chagford, and, we believe, motor cars will soon be doing this journey. The L. & S.W.R. have recently started a service of motor cars from Exeter to Chagford, the distance being covered in some two hours.

#### NORTH OF ENGLAND COLLIERY SURGEONS AND THEIR FEES.

PRIOR to the formation of the Northumberland and Newcastle Medical Association, the colliery doctors in that county were paid by the miners 6d. a fortnight per family for medical attendance, which sum was supplemented by a small fee, varying in different localities, from grown-up sons and lodgers. This rule had continued for sixty years, but with the increased cost of education and of appliances it was felt by the medical men to be insufficient remuneration for a hard class of practice. Abuses, moreover, such as those of committee management, had begun to creep in. Four years ago the Association in question was formed and proved successful both in removing abuses and in raising fees to a minimum of 9d. per fortnight. Recently in several districts (especially in one where the miners had tried to fight this Association by means of imported practitioners) an agitation has been fomented amongst the men, but its leaders not finding their local efforts satisfactory, their delegates referred the matter to the County Miners' Union. At the request of the Union, representatives from the Medical Association met a committee of the Union and discussed the matter. The subjoined relates to the report made by the doctors' committee to this Association and adopted by them.

The difficulty which has for some time been cropping up amongst the miners with regard to medical fees has now entered upon a new phase in Northumberland. A statement has been issued setting forth the particulars of a conference on the subject between Messrs. H. Boyle, R. Young, G. Middleton, A. McKay and S. Morton on behalf of the miners, and Mr. Rutherford Morison and Drs. Cromie, Ruddock, and Bunting on behalf of the Medical Union, in which it is pointed out that since the doctors' fees had been raised wages had fallen 40 per cent. of the percentage above the miners' standard wage, and on this account the medical fees, it was contended, should be reduced.

The medical representatives claimed that the increased fee had not been asked for or granted because the miners' wages were temporarily high. The reasons were—

1. That for sixty years the medical fees for attending upon miners had been sixpence a fortnight. During this time wages in all occupations except medical had largely increased.
2. That sixty years ago a medical degree could be obtained with less than three years of study. Now the least time possible was five years. The time occupied and the expense of obtaining a qualification to practise were double.
3. That four years ago it was made illegal for medical men to employ unqualified assistants; consequently, all assistants must now be qualified, and it was difficult

to get them into colliery practice and expensive to keep them there. The attendance, now given being entirely by qualified men, is of more value than that formerly given; and

4. That the increased cost of drugs, instruments, dressings, &c., added materially to the expense of practice.

The miners meet this by asserting that many of the serious cases are now sent to hospitals, and that it is unusual to perform operations at the houses of patients.

On behalf of the doctors it is held that the advance of medical science has made hospital treatment necessary, and as an example an affliction common and serious amongst miners is given. For the cure of this 295 operations were performed at the Royal Infirmary, Newcastle, in 1903, and in 95 cases out of a hundred the cure is permanent, whilst so lately as ten years ago the operation was seldom performed with hope of success. For these cases no fees are received.

Against this the miners point out that in most colliery districts qualified nurses maintained by the workmen greatly assist the medical practitioners.

The medical representatives, after careful consideration, advise the Medical Association in the following terms:—"That in their opinion it is impossible to obtain and retain the services of qualified medical men of ability and good character for colliery districts at less than the fee of 9d. a fortnight, which was fixed upon as a minimum; that a reduction of the present medical fees would tend to lowering of the standard of medical work, and defeat the endeavour of our Association to increase the usefulness and the skill of our members."

The foregoing having been placed before the Council, the Miners' Association has been empowered to take steps to bring about a reduction of 50 per cent. in the fees now paid, the figures in the proxy vote being as follows:—For, 141; against, 30; majority in favour, 111.

It will be seen that the Miners' Association has been instructed to take steps to have the doctors' remuneration lowered by 50 per cent.

It therefore becomes a matter of imperative importance that medical men should refrain from taking appointments of any description in the county of Northumberland without first inquiring from Mr. Garforth Drury, of 95 Pilgrim Street, Newcastle-upon-Tyne, Secretary N. and N.M.A., or from Dr. Cox, Gateshead, Hon. Secretary North of England Branch, B.M.A.

#### CENTRAL MIDWIVES' BOARD.

MEETING HELD JUNE 30TH, 1904.

DR. F. H. CHAMPNEYS in the Chair.

DR. WARD COUSINS moved that "registered members of the medical profession only be eligible for appointment as examiners under the Central Midwives' Board." It was, in his opinion, eminently necessary that as the teachers were fully qualified as medical men the examiners should be so too, as only such could understand questions bearing on midwifery, and their medical *compagnons* felt very strongly on this point. Take, for instance, the duties of a midwife before and after labour; her duties with regard to sanitation, the feeding of infants, all such are safest to be taught by a medical man.

MR. E. PARKER YOUNG considered it retrogressive not to have fully qualified medical men as examiners.

MISS WILSON objected, considering a woman who taught nursing would be the best to put questions on that subject, and a fully qualified matron was capable of doing this. At any rate, the matter should be left in the hands of the Board. To this

DR. CULLINGWORTH agreed, arguing it might be taken for granted that no unsuitable person would be appointed. Undoubtedly women were fit for their own part of the work, but no strict rule should be laid down as to their appointment.

DR. SINCLAIR considered the matter ought to be finally settled, his remark being seconded by

DR. J. W. COUSINS, who considered nursing as a very high art indeed, and the duties of a lying-in room should be done by the best nurses. How could any woman, merely taught under the flimsy rules of a board of guardians, do this well? She might acquire a vast amount of book learning, but hospital or infirmary practice was absolutely necessary.

THE CHAIRMAN suggested substituting "may" for "must." In certain circumstances a highly trained midwife might be useful on the Board. There were many things a midwife could do better than the doctor, such as making beds and dressing babies, but he had to see that she did them.

DR. J. W. COUSINS here inquired whether medical men were to be asked to collaborate with unqualified persons.

IT WAS finally resolved that the Examining Board should consist of qualified medical practitioners only, the meeting then passing on to consider whether such should be obtained by advertisement or invitation, it being agreed and passed that invitation would produce better applicants. The question of payment was raised by

MR. PARKER YOUNG, who thought that if they were to have one examiner for every twelve candidates (oral) it would mean that he would work only three hours a day, and if not less than two examiners were appointed with a fee of 10s. 6d. for every candidate, where would the working expenses come from, the entrance fee being one guinea? It was finally agreed to reduce the payment to 7s. for each examiner.

MISS PAGET, at this stage, put in a protest against the arrangements for examinations—*i.e.*, that twice yearly the same papers should be given in London and the provinces. She maintained that to wait six months after failure was too long for a woman who had her living to earn.

DR. SINCLAIR, in reply, said a good midwife would not fail. If she did, things ought not to be made too easy, it being finally arranged that the words "oftener if necessary" should be inserted after the words "twice a year in London and the provinces," and an examiner to attend at the various centres of examination even if the candidates numbered below twelve.

#### France.

PARIS, July 3rd, 1904.

#### TREATMENT OF SPRAINS.

THE treatment of sprains depends, says Dr. Morestin, on the period in which the surgeon sees the patient. It is not often that he is called in immediately after the accident; generally one or two days elapse, when the blood has had time to effuse into the synovial bursæ or to infiltrate the cellular tissue. At other times, the accident is several days if not weeks old, and in such cases one is no longer in presence of a sprain but of its complications.

At the outset, the pain must be relieved and infiltration prevented if possible. Later, it will be necessary to obtain the absorption of the effusion, and hinder complications. When, however, the lesion is already of a certain date, these latter have to be treated. Formerly, a large place was given to "blisters" in the treatment of sprains, but they have for a long time fallen into disuse, and rightly so. But cold or hot applications have, on the contrary, rendered good service. Immersion in hot or cold water constitutes, when possible, a simple remedy not to be ignored. Baudens strongly recommended in cases of ankle sprains, plunging the foot in cold water and keeping it there as long as was agreeable to the patient, followed by a compressive bandage. The ice bag or, on the contrary, a hot-water bottle or hot sand are

sometimes excellent resources in sprains of the knee or the hip-joint. However that may be, the real curative treatment consists in mechanical means, by which the tissues are compressed so as to provoke absorption of the blood, lymph, exudations, or consecutive infiltrations.

Of these means, the most ancient is compression. Before cotton-wool was employed, it was a painful and even dangerous method, but with the apparatus as known to-day compression gives very good results. Yet this treatment is insufficient, and can only be justified by the impossibility of having recourse to massage, or the elastic bandage applied in the interval of the baths or the *séances* of massage; thus the apparatus is a means not to be neglected. The elastic bandage is, in the opinion of Dr. Morestin, the most perfect means of obtaining absorption of the blood or any other effusion into the joint provided it is not drawn too tight. Massage is of very general application, although its good effects were long ignored by surgeons. The pressure should be gradual, centripetal, and painless. At the beginning it should be light and superficial, so as to accustom the painful region to the contact of the hands. Gentleness is the principal point in the operation. Massage is particularly successful in ankle sprain. When applied immediately after the accident it works like a miracle. After from ten to twenty minutes of intelligent massage, the patient recovers the use of the articulation. In the case of knee sprain, massage would be rather prejudicial. The elastic bandage should be preferred after the first two or three days of the accident. Massage, on the other hand, is the only beneficial treatment of sprain of the hip and the shoulder, especially if employed at the very first, otherwise, if several days have passed, an apparatus for continued traction to obviate stiffness of the joints should be applied. As to rendering the joints immovable, the day has passed since such useless and hurtful treatment has been employed.

### Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, July 2nd, 1904.

At the Society for innere Medizin, Hr. Eulenburg showed

#### TWO CASES OF ACROMEGALY.

The first was that of a machinist who had an accident three years ago. The speaker had been applied to for an opinion as to the connection between the accident and the now existing disease. The patient was standing before the water-level indicator of a boiler when an explosion took place. In his fright he struck away the object he was standing on and fell among the coals. He had numerous injuries about the face, complained of headache, and had a staggering gait. After a few days he went to work again, but soon had to give it up altogether. After this the symptoms of acromegaly appeared. These were most pronounced about the head, the hands and feet, the trunk, and especially about the vertebral column. There was marked widening and thinning of the sella turcica, and above the sella a half-dark shadow that pointed to tumour of the hypophysis. There were no other characteristic symptoms of tumour, and the field of vision was normal.

The question was: Was the acromegaly a consequence of the accident? The Court of Arbitration had decided not. An objection to this finding had been raised, and the speaker had given his opinion that the possibility of a connection between the two could not be denied. In confirmation of this were the facts that

acromegaly among men was very rare indeed after forty, and that in a collection of fifty-five cases it only occurred after that age in three, and in each case in connection with an accident. It was also a question whether the shock or the injuries, or both combined, should be looked upon as the cause.

The second case was that of a man, *æt.* 25, who had been shot in the face with small shot about four years ago. Some of the shot corns could still be felt under the skin. Some months later the patient took part in some military exercises, and, later, hemianopsia was noted, and at the same time the acromegaly. There had been no change in the condition since then. In this patient also the head, hands, and feet were very much changed, especially on the right side. Röntgen illumination showed widening and thinning of the sella turcica, but there was no shadow above it as in the previous case, so that there was no sign of a tumour of the hypophysis. Here the intracranial symptoms were markedly developed, hemianopsia, phthisis, imperfect action of the rectus internus muscle, polydipsia, hyperidrosis, and scoliosis of the vertebral column.

The speaker finally showed the Röntgen image of a third case, that of a married lady, *æt.* 29, who had never menstruated. For a long time she had suffered from orbital migraine then amaurosis of the right optic appeared, and distinct imbecility. The signs of acromegaly appeared later. The picture showed widening and thinning of the sella turcica and a shadow above it the size of a walnut; here also there was probably a tumour of the hypophysis.

MURETIN.

Hr. Litten spoke on muretin, prepared by the firm of Bayer and Co., and recommended as a depoisoned antifebrin, the daily dose of which was 0.5 gramme in divided doses. It was stated to be a very powerful antipyretic, particularly useful in the pyrexia of phthisical patients. The drug was handed to him for experiment, and the results of these had not corresponded to the promises held out. As regarded its harmlessness he had seen moderate collapse in one case and outbursts of perspiration in every case, that lasted for hours and left the patients exhausted. These sweats were so constant and persistent that patients refused to continue taking the medicine.

At the Surgical Congress the

PRESENT STATE OF THE PERITYPHLITIS QUESTION was discussed by Hr. von Büngner. He would make the attempt to bring about some convergence of the present very divergent views of physicians. He could therefore only discuss certain points. The pathological anatomists had revised their views as to the relation of the vermiform appendix to the peritoneum, as it had been shown that suppuration might be set up by the processus. Its length varied with age and other normal conditions. As regards its walls, the submucosa was the most important part, which was very rich in follicles. In his opinion an acute inflammation preceded the chronic, and not *vice versa*. The inflammation was generally limited to the submucosa and the muscular layer was usually destroyed along with the former. When late attacks came on perforation readily took place in those spots where these layers had been destroyed, and the mucous and serous layers lay together. Whether pus was poured into the peritoneal cavity depended on whether adhesion had previously taken place. There were both an acute and a chronic perityphlitis. The chronic form was usefully treated by operation. The appendix was extirpated so that nothing of it was left behind. In cases of pyæmia, the metastatic collections must be traced

out. In paratyphlitis the lumbar region must be carefully examined. In perityphlitic abscess early operation was indicated. The processus should not be removed unnecessarily, only when it was lying free.

He also distinguished a perityphlitis and an epitiphlitis simplex. Here operation should not be performed in the acute stage, say the moderate surgeons; the radical ones would operate in all cases to remove the threatened danger. In most recent times the majority of surgeons had expressed themselves in favour of early operation, but it involved certain risks. Cases of simple perityphlitis generally ran their course in about five days, and by the second adhesions had formed, which must be broken up at an operation. This involved the danger of leading to general peritonitis. One must decide early whether these cases should be treated surgically or medically. If the decision was to treat them surgically the operation should be performed on the second day at the latest.

### Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, July 3rd, 1904.

#### GENU VALGUM ADOLESCENTIUM.

At the Gesellschaft Aberle exhibited a patient with bilateral genu valgum which, according to the history, had not developed earlier than the ninth year. The Röntgen rays proved the bending to be in the lower part of the femur in both legs.

The proper treatment to be followed was osteotomy, in accordance with the rules laid down by MacEwen and Schede.

#### PATELLAR FRACTURE.

Büdinger had two patients to show on whom he had operated for fractured patella. In both cases he applied para- and pre-patellar stitches without stitching the patella itself. Early passive movement in from five to seven days was applied, with a rapid healing of the fractured parts.

Eiselsberg prefaced a discussion on this form of treating fractured patellæ. He was also of opinion that both active and passive movements should be commenced in the first week of the treatment. Much was said by the following speakers for and against the treatment which might be summed up as speculative.

#### FREEZING RÖNTGEN BURNS.

Riehl showed the society a young woman who had suffered severely from burns on the chest caused by the Röntgen rays, which he had treated successfully by freezing the skin with ether chloride spray.

At the same time he showed a man, æt. 65, on whom he had acted with the Röntgen rays for an idiopathic, hæmorrhagic, cutaneous sarcoma with perfect success, as the morbid condition has now quite disappeared.

Freund remarked that this therapy of freezing in Röntgen ray injuries is consistent with the application of the Röntgen rays in dermatitis. As to the effects in sarcoma he was sceptical, as some do well, while others are unaffected.

Spiegler said he had a peculiar result from the treatment with the Röntgen rays in the case of a lady, whose chin became dark blue in colour.

#### UROSEPSIS.

Kornfeld gave the members a *résumé* of the symptomatology of urosepsis, which, he said, varied from local irritation, like prostatic hypertrophy, stenosis, &c., to the general hæmatic changes in fever. These he divided into (1) Uric fever appearing in an acute, recurring, or chronic form; (2) gastric phenomena; (3) nervous changes such as tetany, migraine, pigmenta-

tion, and trophic disturbance; (4) general enfeeblement or cachexia.

Blum remarked that morbid changes in the male apparatus, like prostatic hypertrophy, produced tetanoid phenomena, known by Trousseau as Chvostek's symptom. He was inclined to believe that the urine was not alone the cause of these tetanoid attacks and thought the prostate was as much to blame as the removal of the thyroid was for myxœdema. Basedow confirmed this connection by producing genital atrophy, which resulted in myxœdema. The very fact of metastasis occurring in mumps points to a glandular connection with the genital apparatus, and knowing that the removal of these glands produce a lowered state of the vitality it is reasonable to believe that the suspension or abolition of the prostate interferes with the poietic function of the organism by withholding some necessary secretion for perfecting the vital force. Another strong argument in favour of the genital origin of many of these diseases is the result of removing the ovaries which we recognise as ovarian cachexia. Is it not probable that atrophy or injury of the prostate will produce a similar result?

Kornfeld could not agree with Blum although he admitted there was a good deal of analogy in his argument. In the ovarian cachexia referred to, a number of the phenomena were present that dissociated it from the prostate; and furthermore very many cases of prostatic parenchyma destruction are met with where no cachexia exists.

#### THYROID GLAND AND EPITHELIAL CELLS.

The discussion on this subject was resumed. Pineles read a paper some time ago attributing the changes in the gland to alterations in the epithelial cells.

Escherich disagreed with Pineles' theory of the insufficiency of the epithelial cells being the cause of the tetany. In children, where tetany is more common under one year of age, the connection is more likely to arise from improper feeding than insufficient epithelial cells in the thyroid.

Jonas put forward "Gastric dilatation tetany" in support of Pineles' theory. The dilatation, he contended, was not the cause of the tetany, but an accident in the course of the morbid changes, while the insufficiency of the epithelial corpuscles could not be said to be due to the dilatation.

Loebl thought [the tetany in gastro-intestinal diseases could not be called accidental, as gastro-enteritis when severe always produced the Chvostek-Erb and Trousseau phenomena. In addition to this Italian experimenters have removed the cœliac plexus and produced tetany with all the associated symptoms.

Redlich concurred with Pineles in the belief that injury to the epithelial cells of the gland was the cause of the tetany. It is unfortunate for this argument that no exact proof can be brought forward to substantiate either hypothesis, but from the weight of inference adduced the proximate cause seemed to preside in the epithelial cell.

Frankl-Hochwart did not agree with Pineles, and would only ask one question, which he thought most pertinent. Why is it that tetany is so seldom met with in the site of the thyroid gland if it be due to insufficient epithelial cells? To this Pineles answered that the question supported the theory of cell insufficiency.

In the cretin the gland itself was only affected, while the epithelial cells remained unaffected.

In answer to those who had compared children, he quite agreed that the symptoms resembled strumipriva.

but were not exactly the same. The experiments of Königstein on animals conclusively proved this: that as soon as the epithelium appeared the tetany disappeared. It is possible, however, that gastro-intestinal affections may have the effect of reducing or otherwise rendering the epithelial cells inefficient, which would consequently produce tetany as expected.

### EGYPT AS A HEALTH RESORT.

[BY OUR SPECIAL TRAVELLING CORRESPONDENT.]

WITH your kind permission, I shall venture to give you some idea of the climatology of certain parts of Egypt, and inasmuch as so many who, after taking a tour of a few weeks only in Egypt, go back to their native country and compile works containing the climatic phenomena of the country, bearing pompous titles, as "Egypt and the Egyptians," or "Pharo's Egypt," &c., I may, perhaps, be excused as an individual who has resided for some considerable time in Egypt, with a good knowledge of Arabic and Egyptian biology, if I presume to pen the following. In this I shall try to give an outline of the climate and other interesting points of Suez, Geb-el-Tor, Ismailia, Port Said, Alexandria, Cairo, Luxor, Assouan, and Wady Halfa, leaving my fellow-practitioners to draw inferences and to recommend one or the other place as to the suitability of the patients under their care.

Suez is a small port inhabited chiefly by European employes of the Suez Canal Company, as well as by the different coaling agents and their clerks and a very limited number of merchants, and the main branch of the Eastern Telegraph Company and staff, having their own building, club, cricket and football team, &c. The residents of Suez, excluding the Egyptians, are composed of Greeks, Maltese, English, Italians, and the remainder mostly Austrians of different sects.

Terre-Pleine is about five minutes run from Suez town, where there are the Suez Canal offices, Suez Canal workshops, and shipping and coaling agencies; it is kept very clean, with a pleasant avenue and a good view of the harbour and canal. The residents from the balconies of their houses (which are situated on the Canal border) can see the transit of the different ships homeward and outward bound; hotels also exist at Terre-Pleine, the oldest of which is the Hôtel Bachet. The climate of Suez and Terre-Pleine during the months of July, August, and September is almost unbearable, but the heat is dry and no diseases prevail, except some cases of sunstroke and purulent ophthalmia, which can be avoided. During the winter season the climate is temperate, dry, and bracing, and, I believe, most suitable for persons suffering from asthma, rheumatism, and phthisis; but in summer I would not recommend the place to any. There are several well-known practitioners, of whom Dr. Creswell, principal medical officer, Government Hospital; Dr. Attfield, Director Quarantine Office, and Dr. Gautier, principal medical officer to the French Hospital, may be named.

Geb-el-Tor is a quarantine station on the Red Sea, about 100 miles from Suez, the inhabitants of which are for the most part Copts, appertaining to the Greek Orthodox Church. A branch chapel of the Grand Cathedral of St. Catherine of Mount Sinai exists at Geb-el-Tor. There is no vegetation bar a garden belonging to the said church, which is cultivated by the monks for their own consumption; there are no hotels, very few houses, practically speaking no trade, and steamers only call at that port in time of the Mecca Pilgrimage to obtain their "libra pratique" for the Canal. During the rest of the year a Government steamer runs to and fro during certain dates to supply the quarantine camp and the employes with their necessaries. What I desire to point out in this station is, that a natural thermo-mineral spring exists, called Mammram Mousa, which means Moses' bathing-place, encircled by a low mud and stone wall of very old standing, with different names engraved on the wall by Arabs and Europeans who had called there—but certainly not as the Arabs

believe—from the time of Moses. The waters of the said spring were analysed by me, and they contain sulphur, sodium, calcium, lithium and traces of iron and iodine, and I believe them to be very valuable in gout, derangements of the liver and in syphilis. Kindly note that I am writing from experience, and not merely re-echoing other people's belief. I therefore recommend those suffering from the above complaints, who have tried the Continental waters without any obvious benefit, to try once again the thermo-mineral spring at Geb-el-Tor, during the Mecca Pilgrimage, as then the tourist will be able in one way or another to find through the quarantine staff some suitable accommodation. The climate in winter is dry, bracing, and temperate; in summer it is very warm, but almost always with a favourable breeze during the evening; it is the healthiest spot in Egypt.

Ismailia is the centre station between Suez and Port Said, with the Suez Canal head offices; it is very neatly kept, there are many gardens, and vegetation is in abundance, but it is very monotonous and unhealthy. Malaria and intermittent fever prevail. The climate in summer is very warm, and in winter very damp; there are several hotels and, but for the Canal Company's offices and the cleanliness of the town, nothing is worthy of note.

Port Said is one of the most important coaling stations in the world, with a great many English firms, shipping agencies, and residents, in fact, the British population form the Port Said aristocrats, and by including the British subjects the importance of the town trade might be said to be ruled by them. Next comes the Greek population, and the remainder is composed of French, Italians, Austrians, and Montenegrins. The climate in summer is warm and damp; in winter, very damp and foggy; the town is not very clean and there are no gardens. Port Said, broadly speaking, is unhealthy, every other person is subject to neurasthenia, every three out of ten to rheumatism and gout. But should any tourist intend visiting Egypt, I would advise him to visit Port Said; there are several very good hotels, of which the Eastern Exchange is the most attractive. The town is always in motion on account of the different steamers that coal there and the landing of their passengers. The cafés, casinos, hotels, bars, shops, and the pidgin-English made use of by the Egyptians is worth while seeing and hearing. Port Said has some competent practitioners, Dr. Cuffey and Dr. Grillet (English), and several of French nationality.

Alexandria is a well-known city, and several English steamship companies have a regular service to that port. It is a very pretty place, with a large number of British residents and a well-directed municipality, which tries to put into execution all the latest sanitary improvements. Alexandria possesses some very good hospitals, of which the Greek hospital is the leading one, not only from a sanitary point of view, but as regards treatment and nursing, and is under the able management of Dr. Valassopoulos. Then comes the Deaconess' Hospital (also called the Prussian Hospital), of which Dr. A. Morrison is a regular attendant and who is not only a very capable surgeon but possesses in a high degree that *savoir faire* which is decidedly attractive to his extensive connection. As far as the sanitary arrangements of the hospital itself are concerned, some urgent things are lacking, but this is entirely due to the management, and not to the surgeon. Then comes the French hospital under the able management of Dr. Legendre (French) and Dr. Massa (Italian), and very shortly an English hospital will be built, as the funds for its construction are daily flowing in. The life at Alexandria is gay, the town is full of cafés, bars and other places of amusement; there are some very good Turkish baths of which El Hammam el Masri, situated at Sikkhat el Warsha, bears the palm. Half an hour's distance from Alexandria is San Stefano, with its beautiful casino and sea baths, and where every tourist can enjoy his bath and breakfast at a very reasonable price. Alexandria possesses the St. Andrew's School, having at its head Mr. A. Buchanan, M.A. As for the

climate, Alexandria is very damp in winter, and unsuitable for people suffering from constitutional diseases; in summer it is warm. The town is well worth visiting, and should any tourist require medical advice he may unhesitatingly and with entire confidence place himself in the hands of Dr. A. Morison or Dr. Legrand. Influenza and hepatic disorders are the prevailing diseases. In my next I shall treat of Upper Egypt.

## The Operating Theatres.

### MIDDLESEX HOSPITAL.

**CHOLECYSTECTOMY.**—Mr. JOHN MURRAY operated on a woman, *æt.* 46, who had been admitted with the following history:—In 1898 she had had an attack of pain on the right side with swelling; this was followed by jaundice. In 1901 she had a similar attack. Four weeks before admission she complained of pain in the epigastric region, accompanied by vomiting and marked tenderness in the right hypochondrium; a distinct swelling could be felt, somewhat ovoid in shape, extending about three inches below the costal margin. This last attack was followed by jaundice. On admission, the patient still had pain in the right hypochondrium, some tenderness on palpation, and a distinct swelling could be felt in the region of the gall-bladder. There was no jaundice. The woman's general condition was good. Operation was decided upon. A five-inch incision was made splitting the fibres of the right rectus, and the abdomen opened. The gall-bladder was adherent to the structures around, and when the adhesions had been separated the gall-bladder was drawn up into the wound and incised after sterilised gauze had been packed all around so as to shut off the peritoneum. It was found to be very much thickened and to contain a number of calculi; these were removed with forceps and scoop. After the gall-bladder had been cleared out the cystic duct was examined, and was found to contain calculi. On attempting to reach these through the gall-bladder the wall of the latter split longitudinally, and as the communication between it and the duct was so small that it was impossible to remove the stones through the gall-bladder, Mr. Murray therefore decided to remove this organ. It was therefore freed from the under surface of the liver, and was then easily drawn out of the wound, and the calculi in the duct extracted by slitting up the gall-bladder a little further. The gall-bladder was then removed and the stump of the cystic duct stitched to the peritoneum. The wound was then sutured in layers and a small tube inserted into the dilated portion of the duct and another into the peritoneal cavity at the lower part of the wound, which was then dressed. On counting the stones there were found to be thirty-eight, most of them being of moderate size. Mr. Murray said that in this case the diagnosis was obvious. Three attacks of pain, each followed by jaundice, and the presence of swelling in the region of the gall-bladder in the last attack, all pointed unmistakably to the presence of gall-stones. It was decided to operate, he pointed out, first of all because there had already been three definite attacks, secondly, because the gall-bladder could be felt distinctly four weeks after the onset of the last attack, and lastly because the pain and tenderness had persisted. With reference to the operation, he said that he preferred the incision through the rectus itself, splitting the fibres, to an incision in the semi-lunar line, because the wound was more easily brought together subsequently and there was less danger of a ventral hernia. With regard to the removal of the gall-bladder, this, he said, was necessary owing to the splitting of the organ during the

attempts to extract the stones from the cystic duct; the ease with which it tore was owing to the fact that the wall was enormously thickened, the thickening being due to the presence of inflammatory infiltration; apart from this, removal was the easiest way of extracting the stones from the cystic duct. The thickened and infiltrated state of the gall-bladder rendered its removal advisable. In speaking of the treatment he had employed for the duct, he said it was the safest on account of the quantity of muco-pus in the gall-bladder; for the same reason the tube had been introduced into the peritoneal cavity.

The tubes were removed on the third day; at the end of a week some bile appeared on the dressings, and this continued for a fortnight and then ceased. The patient left for a convalescent home a month after the operation.

### FRENCH HOSPITAL AND DISPENSARY.

**OPERATION FOR APPENDICITIS—INTERESTING FAMILY HISTORY.**—Mr. CLAYTON GREENE operated on a woman, *æt.* 20, who had been admitted for appendicitis, with the following symptoms: Pain in right iliac fossa, vomiting, and constipation. On examination, definite resistance was found in the right iliac fossa. The temperature was 101° on admission, but came down in two days, after a treatment consisting in the administration of a drachm of magn. sulph. every half hour. At the operation, the appendix was found with its tip glued down by adhesions in the pelvis. The adhesions having been broken down, the appendix was brought to the surface and found to be very congested and covered with a network of vessels. It was rather thickened, but no concretion could be felt. On slitting open the appendix no concretion was found, but only a small quantity of viscid mucus. The appendix was removed by turning back a cuff of peritoneum, next passing a purse-string suture round the cuff, then removing the appendix, and turning in the free edge of the peritoneum so as to get the stump of the appendix inside the cuff, and, finally, drawing the purse-string suture tight. The wound was closed in three layers. The peculiarity about this case was that the whole family, *viz.*, the father, the mother, two brothers, and two sisters, and the uncle, all had suffered from appendicitis. The mother died without operation, the uncle and two sisters were operated on and recovered, and the two brothers recovered without operation.

The patient's temperature never rose after the operation, and in a week she was convalescent, the pain and tenderness having disappeared.

### Medical Sickness and Accident Society.

THE usual monthly meeting of the executive committee of the Medical Sickness, Annuity and Life Assurance Society was held at 429 Strand, London, W.C., on the 24th ult. There were present Dr. de Havilland Hall in the chair; D. J. Pickett, Dr. St. Clair B. Shadwell, Mr. J. Brindley James, Dr. M. Greenwood, Dr. Walter Smith, Dr. W. Knowsley Sibley, Dr. F. J. Allan, and Dr. J. B. Ball. The accounts presented showed that the business of the Society is satisfactorily growing. Each year a large addition has been made to the funds, which now amount to £180,000, and it is estimated that during the current year more than £10,000 will be paid to the members as sickness allowance. The list of those permanently incapacitated shows no sign of lessening although several deaths have occurred among them during the last four months, but fresh cases have come forward, and the number of those who have to draw annuities, generally one hundred guineas a year, steadily grows. Prospectuses and all particulars on application to Mr. F. Addiscott, Secretary, Medical Sickness and Accident Society, 33 Chancery Lane, London, W.C.

WEDNESDAY, JULY 6, 1904.

**THE IMMUNISATION OF PERITONEAL WOUNDS.**

THE extreme sensitiveness of the peritoneum and its peculiar liability to septic infection are the chief factors with which the surgeon has to contend in any operation upon the abdomen and its contents. Wounds of this serous membrane so lower its resistance that it becomes a more easy prey to septic organisms, while the *bacterium coli* itself is well known to acquire, under certain conditions, pathogenic properties. Peritoneal infection from the mucous membrane of any part of the gastro-intestinal tract still occurs with too great frequency, in spite of the most elaborate precautions. We are here face to face with a grave problem, namely, the prevention of such infection and the consequent diminution in the mortality after operations upon the stomach and intestines. In certain diseases characterised by an invasion of the system by specific organisms, which at the same time secrete toxins, we have, to some extent, the power of producing an artificial immunity by the injection of a specially prepared serum, or antitoxin. Successful as many of these sera have been, there is an undoubted difficulty in adjusting or adapting them to the varying strains of the same organisms, the virulence of which is seldom constant. This is a disadvantage which will be gradually overcome by greater perfection in bacteriological technique, as well as by an increased knowledge of the life history of pathogenic germs. Many experiments have also been undertaken with a view to the preparation of prophylactic sera, a few of which have been put to practical use, as, for instance, in the inoculation against typhoid fever. The other method, and the only one which, in the present state of our knowledge, is applicable to infectious conditions of the peritoneum, is that

of increasing the power of resistance of the body against bacterial invasion. This aspect of immunisation is the one dealt with by Professor von Mikulicz, of Breslau, who delivered before the West London Medico-Chirurgical Society the Cavendish Lecture, published in our present issue. The production of a hyperleucocytosis is one of the means by which this increased resistance is attained, and the experiments of Loewy, Richter, Jakob and Hahn have shown that certain animals have been rendered immune against pneumococcal and septicæmic infection by the injection into their bodies of substances capable of exciting hyperleucocytosis. Intra-peritoneal injections of normal saline were employed in 1902 by Salieri for the purpose of increasing the resistance of the peritoneum against infection, while Issaëff had also experimented in the same direction. The possibility of thus immunising peritoneal wounds in the human subject has been made a special study by Professor von Mikulicz, after further experiments had been undertaken upon animals by all the different methods tried. A 2 per cent. solution of neutralised nucleic acid was found to be the most efficacious in producing hyperleucocytosis. This was injected in man subcutaneously, in quantities of 50 c.c., and in no case was any serious local or general manifestation observed. In all, fifty-eight cases were thus injected, fifty-five of which were operations upon abdominal viscera and three of extra-abdominal disease. The only sign of reaction was a slight rise of temperature during the first few hours after the injection. As far as results are concerned, the number of cases treated in this manner is admittedly small, but in forty-five laparotomies in which the peritoneum was exposed to infection from the contents of the stomach or intestines, seven only were fatal, and in none of these was post-operative peritonitis the cause of death. The operations were undertaken on the "rising tide of leucocytosis," which attains its maximum in man about ten or twelve hours after the preventive injection. Solutions of normal saline appear also to have the power of increasing the resistance of the peritoneum to *B. coli* infection, hence the practice adopted by many operating surgeons of irrigating the peritoneal cavity with this fluid after laparotomy would seem to be based upon scientific principles. This method of producing artificial immunity of the peritoneum should prove of great advantage to surgery in general, and, if confirmed by subsequent observers, will do much to rob operations upon the abdominal viscera of their dangers.

**PUBLIC HEALTH ADMINISTRATION.**

FOR many years business men have been anxious to see the Board of Trade re-modelled, and its Parliamentary chief raised to the dignity of a Secretary of State, whilst those interested in social matters have been advocating that a similar process of transformation should take place at the Local

Government Board. As the result of these agitations a Committee was appointed by the Treasury last year, charged with the duty of investigating the two proposals. Their report has just lately been issued, and it cannot be said that its recommendations will be very satisfying to those ardent spirits who wished to see a Minister of Public Health, with all the dignity of Cabinet rank, created to infuse vigour and initiative into the public health administration of the country. The Committee has taken a narrow view of the terms of reference supplied to it, and, with regard to the Local Government Board, has confined itself to the question of the salaries paid to the higher officials in making positive recommendations. These recommendations are in themselves a step in the right direction, for they propose that the President's salary shall be raised to £3,000 a year, and those of the Parliamentary and Permanent Secretaries to £1,500 and £2,000 respectively. On the accepted principle that people value a man's opinion in proportion to what they pay him for it, it may now be anticipated that the prestige of the Local Government Board will be somewhat increased if the Committee's recommendations are adopted, but that is all. On the negative side, however, it is to be noticed that the Committee had before it two suggestions, both of which it rejected. One was put forward by the British Medical Association, and embodied the views of the Council that the President of the Board should be a Secretary of State, with full emoluments and status; that one of the members of the Board should be a medical man, and that the administration of the Medical Acts should be transferred to the Board from the Privy Council. The other was that of the Public Health Committee of the House of Commons, presented by Sir Michael Foster, advocating that the health duties of the Board should be divorced from those relating to the Poor-law, and taken over by a separate staff acting under a Parliamentary secretary. The Committee thought, with regard to the proposal of the British Medical Association, that the duties of the Board were already sufficiently onerous, and that it would be a mistake to increase them, whilst it held that to adopt Sir Michael Foster's proposals would be attended with considerable practical difficulty. It may, therefore, be taken as settled that any change in the constitution or organisation of the Local Government Board is out of the question for the next few decades, and the public health administration of this country will continue to proceed on its old lines for good or for evil. It is a great pity that this opportunity for reform has been lost. The growth of the Local Government Board's work since its institution in 1871 has been prodigious, and it is now the largest of the Government departments. Every day almost sees an increase in the business it has to transact. Interest in matters relating to local government has grown more and more as people have realised that their interests lie in their own hands, and that if they suffered from disabilities and grievances,

it is due to their own inertia in not removing them by constitutional means. But with the healthy devolution of powers it has been found necessary to keep a firm control over irresponsible and extravagant boards by the central organisation, and, on the whole, it must be admitted that the influence of the Local Government Board has generally been for good. Still, the complex and multifarious duties of the Board are such that administrative jumbles cannot be avoided, and when the importance of safeguarding the public health in our present crowded towns and cities is considered, it is of the greatest moment that a strong, well-staffed and vigorous Board should be available to co-ordinate and control the policy of the various authorities carrying out the Acts in the districts they serve. The association of the poor-law with public health is not a happy one, for, however much one may wish the former to be construed humanely and intelligently, it has not the vital effect on the very existence of the community that the Public Health Acts have, and, like poor relations, it tends to bring obloquy on its associates. Drains and water-works do not fire the public imagination, and when they are joined with workhouses and casual wards, they tend to be looked upon as unfortunate necessities—that are best left to other people. The situation may be summed up by saying that the whole of the public health administration suffers from lack of dignity, and that while the Local Government Board continues to be a minor office, as a reward for a good party hack, in which he may serve his apprenticeship to the higher grades in the Cabinet, so long will the public health service continue to be regarded as of secondary importance to the State. Any hope of seeing it otherwise is postponed indefinitely by the Committee's recommendation.

#### HOSPITAL ABUSE.

WE have for several years past, whenever the opportunity offered, impressed on our readers the magnitude of the evil involved in the present system of hospital administration, and we have done our best to suggest the lines along which reform should take place. At present, there is little doubt that the class for whom hospitals have been founded and are maintained—the necessitous poor—is not the class who make most use of them. On the contrary, the wards are occupied and the dispensaries crowded by well-to-do artisans and people of the lower middle class, who ought to be, and are, able to pay for medical attendance. A double injustice is thus done: the money contributed by the charitable public is to a large extent misapplied, and at the same time the general practitioner is deprived of his legitimate means of livelihood. In addition, and perhaps of even greater importance from a sociological point of view, is the concomitant pauperisation of a large class of the community. The persons responsible for the present state of things are primarily the governors of hospitals, for it is to them that the administration of the hospital

funds has been entrusted by the charitable public. The responsibility, however, does not end with them, for it is the duty, in this, as in other matters of hospital management, of the medical profession in general and of hospital physicians and surgeons in particular, to keep the boards of governors in touch with the best opinion. In a previous discussion (a) of this subject, we laid down what we thought should be the guiding principles of hospital boards in the matter—"efficiently to relieve the greatest amount of suffering with the maximum amount of economy that efficiency will permit, and to see that funds collected in the name of charity are expended in the furtherance of charity." To aid in the carrying out of these principles, we suggested that inquiries should always be made as to the means and circumstances of patients attended at hospitals, and that, if necessary, a special officer should be appointed whose duty it would be to make such inquiries, and verify them by further investigations if thought advisable. Although but little attempt has yet been made either by hospital boards or by the profession to inaugurate any serious reform, it is something that the profession is at length being roused to take an interest in the matter, and as a sign of this we welcome the action of the Dublin Division of the British Medical Association in requesting its Executive Committee to inquire into the alleged abuse of Dublin hospitals and their dispensaries. The special report drawn up is being considered at the annual meeting this week, and deserves very serious consideration. The Committee state what, indeed, is notorious, that patients who are able to pay for treatment outside are at present in receipt of hospital relief and treatment, and they are of opinion that the only practical way to meet this abuse is to compel such persons to pay for the treatment received. While we are in the main in agreement with these expressions of opinion, and believe that the only way to exclude undeserving patients from hospital relief is to charge them a fee commensurate with what they would pay for similar advice elsewhere, we fear that some of the suggestions made by the Committee are liable to be misunderstood. As long as the charging of fees for hospital treatment is used simply as an instrument of protection from imposture, it is both admirable and effective, but if it is to be used to any degree as a means of income, for either the hospital or its medical staff, it is liable to very serious abuse. A card which the Dublin Committee suggest for use by the governors of Dublin hospitals in recommending patients for treatment, in its present form, at any rate, would leave the way open for some misuse. It consists of two alternative forms of recommendation; one, in the case of needy patients unable to contribute anything, and the other recommending so-and-so "as a pay patient, unable to pay more than £— per week for treatment." It seems to us that the latter

clause may act in quite the contrary way to the intention of those who framed it, and might simply result in turning the general hospital into a gigantic general practice, which, aided by its prestige, influence, and funds, could compete with neighbouring practitioners at cut-rates with disastrous results. As we know nothing could be further from the intentions of the Dublin Division than such a result of their action, we venture to draw attention to this matter of detail, while fully concurring with the general views of the Committee as to the desirability of testing the means of all applicants for charitable medical relief.

## Notes on Current Topics.

### Criminal Charges and Insanity.

BRITISH law is a complicated engine that creaks ominously as it wins along its slow and laborious journey. Criminal law is at present administered by the police, whose one desire appears to be to shut up as many persons for as many years as magistrates and judges will permit. As a rule, unsupported evidence from a police constable is practically law, a fact which helps him not a little in attaining the highest possible position in the force, namely, that of a constable who has never failed in a prosecution. The scientific treatment of criminology is unknown in our law administration. An accused person may be palpably mad as mad can be, but nevertheless be committed to gaol for short or long terms of punishment. The need of some advisory board of lunacy experts was shown last week at the Old Bailey. A woman, formerly a prisoner at Lewes Gaol, on her release from that place brought an action for breach of promise against a major-general of the neighbourhood, one of the visiting justices. The action was fantastic, grotesque, and erratic, and naturally failed. Subsequently the plaintiff was prosecuted for perjury, and in a first trial the jury could not arrive at a verdict. In the second trial she was found guilty and sentenced to four years' penal servitude. With the propriety of that sentence we are not here concerned, beyond pointing out that the first jury clearly thought there was room for doubt. The point to which we would call attention is that the state of the prisoner's mind was not scientifically determined. The Common Serjeant, who tried the second case, asked if there was any reason to suppose the woman was wrong in her head. Then up and spake a bold detective-inspector, "Oh, no! my lord. She is a very wicked, dangerous and clever and designing woman." That illustrates the average attitude both of the police and of the lawyers with regard to mental responsibility of alleged criminals. It seems incredible that the Common Serjeant of London should be content to take evidence as to mental soundness from a policeman. But there is a glimmer of hope, for we no longer hang for petty thefts, and have we not the Bertillon methods of detection, and a First and a Juvenile Offenders Act?

(a) MEDICAL PRESS AND CIRCULAR, August 28th. 1901.

### The Post Office as Censor.

WE have often complained of the inertia shown by the Post Office authorities both here and in America in regard to the nature of the advertisements which pass through the mails. Although it is in print as a rule of the Office that no indecent printed matter shall be allowed to pass, it is notorious that we are pestered day by day by advertisements of various proprietary medicines which are offensively indecent, not only in printed matter but in accompanying illustrations. In the lower class of our own newspapers, also, and in many American journals, advertisements inciting not merely to immorality, but to actual crime constantly appear, and the papers have a wide distribution through the post. Under the circumstances, it is good news to hear that the United States Postal Department have at length determined to institute an effective censorship against the passage through its channels of offensive advertisements. The regulation is to apply, not merely to indecent advertisements, but to announcements of patent medicines and other quack remedies wherever chemical analysis reveals premeditated fraud. It will be enforced also against newspapers, which, after warning from the Post Office, continue to admit quack advertisements to their columns. In all such cases, the papers will be excluded from the mails. The energies of the American postal officials will be fully occupied for some time to come in deciding, as they promise to, "every case on its merits." As a consequence, moreover, their exchequer and our waste-paper baskets will be somewhat the lighter.

### Gas Stoves.

IN and around London the old-fashioned home is gradually tending to disappear. The working-classes, aping their (so-called) "betters," are deserting houses and cottages for flats and those euphoni-ously-named substitutes for all that is desirable, "maisonettes." The artisan and the labourer no longer settle down to the enjoyment of love in a cottage, but wander about and migrate from one quarter of the city to another. Their houses are no longer their castles, but mere shifting tabernacles, and their aim is to limit as far as may be the expenditure of time, thought or money upon the environment of the dwelling to what is absolutely necessary. Anything, therefore, that saves trouble is welcome, and the gas-stove, rented from the company, undoubtedly economises the energies erstwhile devoted to cooking with the old-fashioned kitchen range. A penny-in-the-slot provides a supply of gas, and there is an end of the matter; the old bother of making up a fire or of cleaning the grate has vanished. But the ease thus obtained is dearly purchased, for these gas-stoves are provided with no adequate shafts to conduct their fumes into the external atmosphere, and, consequently, the products of combustion are retained in the kitchen, or find their way by diffusion into the bedrooms. A more unhealthy

contrivance could scarcely be imagined. The carbonic acid, sulphurous acid, and other products of combustion, accompanied by the fumes of volatile fats and particles of organic material from the food that has been cooked, contaminate the air of the building, and are breathed and re-breathed by the whole family. Nor are the working classes the only sufferers in this respect. The same reasons that lead them to use gas for cooking influence those of the upper classes who live in flats and small houses; and although—from the greater air-space available—the family are not so much affected, the servants who pass their time in the kitchen are poisoned daily. No gas-cooking apparatus should be allowed to be used, unless provided with a thoroughly efficient extract shaft for the products of combustion. Let him who doubts these things look at the walls and the ceiling of a room where a gas-stove is in frequent use.

### Lilies versus Roses.

UNTIL comparatively recent years one used to expect a certain amount of good sense in newspapers during the major portion of the year, relieved by nonsense only during the few weeks in the heat of the summer, when "copy" was scarce and the regular writers either slack or holiday-making. But with the phenomenal growth of journalism during the last twenty years or so, it has been found impossible to maintain a high standard of accuracy and interest—at any rate in the less responsible journals—and nowadays nothing seems too silly to "fill up" the columns of some of our contemporaries. A paragraph is going the rounds of the ladies' papers, by far the worst offenders, that a "foreign chemist" has made the brilliant discovery that the lily of the valley has a depressing effect on the heart, so that a spray worn by a lady on her bosom will make her appear cold and listless, though were roses lying there she could be responsive enough. The only hearts that are likely to be depressed are those of the medical men who read such stuff as this. The lily of the valley is one of the oldest medicinal plants known, and though it had almost become obsolete at one time, it has recently been growing in favour, as its active principle, convallaria, has an action remarkably like digitalis, and when that drug acts unfavourably, convallaria is often used as a substitute. Although a rather active poison, convallaria in small doses is a cardiac tonic, and if the odour of the lily of the valley could exert any therapeutic influence—which is inconceivable—it ought to be a stimulating one, whilst the rose is medicinally one of the most inert of plants. One can assure the ladies, therefore, that if they wish to add to their charms by wearing the most modest of flowers, they may do so without fear of ulterior consequences, and that the lily of the valley is, if anything, more likely to stimulate their hearts than the rose of Sharon. Possibly, after all, the writers of this amusing fiction had in their minds former experiences of joy or sorrow

produced in their own masculine bosoms by the sight of roses or of lilies worn by lovely woman.

#### Removal of the Gasserian Ganglion.

THERE are few accepted operations in the range of surgery which appear at first sight more difficult of accomplishment than the removal of the Gasserian ganglion, and it is not to be wondered at that few except the most courageous surgeons have so far been found to practise it. Yet there is no operation which is more urgently demanded in certain conditions than this, since in cases of persistent and so-called "intractable" trigeminal neuralgia it stands out almost the only treatment which may substitute a life of ordinary comfort for one of intolerable misery. At the same time, the operation is not by any means so hazardous as is generally supposed. The mortality during the past two or three years has been rapidly lessening, and in the hands of Sir Victor Horsley, who has operated on as many as 120 cases, has run as low as 2½ per cent. The higher rates of mortality in the practice of other surgeons are due, not so much to any want of skill in the actual performance of the operation as to a reluctance to undertake it before the patient has become exhausted by continued pain, loss of rest and food, and often by narcotic drugs. Surgeons who, following Horsley's example, have had the decision to operate early, have not, as a rule, had any difficulty in obtaining results as good as his. It should be remembered, however, that the operation is one of the most serious that can be performed, and it should never be undertaken by a surgeon who is not thoroughly conversant with the anatomy of the floor of the cranium and the parts adjacent thereto.

#### Efficiency of Surgical Dressings.

It is curious how little fixity of knowledge there is as to the relative advantages of the various materials used in surgical dressing. Each surgeon has, as a rule, his favourite materials, which he uses with but little variation, though from time to time he drops one or other from his store, and substitutes something new. He, indeed, usually places implicit confidence for all purposes in the substance he is using at the moment, though it captivates his good opinion but for a short time. He is, however, rarely ready to offer any scientific grounds for his use of a particular material. He finds it work well, and he is doubtless right to hold by it, but it would be more useful to himself and others to make some inquiries as to the points in which it is successful, and the points where it fails. It is to satisfy themselves in a scientific way as to the efficiency as drainage materials of various popular surgical dressings that Drs. M'Gregor and Ramsey, of Glasgow, have performed a series of experiments recently communicated to a contemporary. (a) Working with absorbent wool, wood-wool, cellulose, boracic lint, and various gauzes, they tested the powers each material shows in absorbing and in

conducting moisture. It is to be noted that the two properties are not at all identical, for some of the materials which were able to suck up moisture with ease were but badly able to transmit it. Again, some materials, while acting as excellent drains of fluid, were quite unable to convey cellular elements. Speaking generally, the observers come to the conclusion that for the transmission of fluids with solids in suspension, dry boracic lint forms the most efficient drain. Cellulose wadding is nearly as useful, but its friability renders it difficult of application, unless enclosed in gauze. As a simple mop or sponge to apply to an open wound, absorbent wool and cellulose are found to be equally trustworthy. It is important to note that even the best drain gets blocked in less than eight hours, so that a more frequent dressing than is customary is indicated.

#### Foot Massage.

It is refreshing to hear of a really sensible American craze, especially when the goodness thereof threatens to invade our shores. The report comes that we are to be inundated with a wave of "foot massage," a form of chiropody that aims at restoring the function of the toes so that they may be able to perform the movements that Nature designed them to execute. But it is not so much the foot massage itself that deserves commendation as its corollary, namely, that pointed toes and tight boots will go out of fashion. If the toes are to be made capable of flexion and extension at will, it is obvious that the massage will be of little avail if, in the interval between the treatment, the toes are to be encased in boots which pinch and restrict them. It will be necessary for the art of the masseur to be backed up by the common sense of the subject, and if this entails the wearing of well-fitting boots and shoes, not only will the practitioner be relieved of many of his difficulties in treating bunions and ingrowing toe-nails, but many ladies will sigh with relief to think that they can enjoy a comfort in walking that fashion has denied them for so many years. Let the foot masseur come and do his best; if he succeeds where doctors and their warnings have failed, they will not grudge him his success.

#### The Dual Aspect of Medical Practice.

THE calling of medicine is one which may be viewed from many different standpoints. The most lofty is perhaps that which regards the physician as the true exponent of the healing art, equipped with special knowledge, and endowed with powers wherewith to combat disease in every shape and form. The practitioner thus stands before all men on a higher plane, ever ready to give, and to give freely, to all and sundry who apply to him for relief from their sufferings. This is the humanitarian view which supposes that the doctor is actuated by no other motive at any time than that of pure philanthropy. We are proud to believe that many from among our ranks have, indeed, served their day and generation without

(a) *Brit. Med. Journ.*, June 11th, 1904.

ever a thought of reward, and out of pure love to their fellow-creatures. Would that it were possible for every member of the profession so to practise, but, unfortunately, such an ideal is out of the question, save for a privileged few. The commercial aspect of medicine forces itself upon the attention of the majority of its practitioners, producing a jarring note upon the ears of many, but to others, unwillingly perhaps, in the first instance, it offers the only possible solution to a life which could scarcely exist at all were the highest ideals to be slavishly followed. Regarded from this point of view the medical man or woman is only a skilled workman whose services have a definite money value in the world's market. The doctor must live as well as his patient, though the latter often fails to recognise the fact. Public bodies, and even the State itself, also ignore it, with the result that a great outcry is made whenever a medical practitioner ventures to assert his rights and demands payment for his services. Too much gratuitous work is demoralising to the public, and must slowly tend to the destruction of the physician's humanitarian instincts. Every labourer, even those in the field of medicine, is worthy of his hire.

#### Two Sides of the Body.

THE belief in the inferiority of the left side of the human body is one of those popular superstitions which have been handed down from remote ages, and which is shared, to some extent, by the members of a learned profession even at the present day. It is well known, for instance, that pain is more frequently felt upon the left side, and it is quite a common saying among gynaecologists that the sinister half of the body is the weaker and less resistant. Sometimes there is an anatomical explanation for this, as, for example, the presence of a loaded sigmoid flexure. The mode in which the spermatic veins empty themselves may account, in some degree, for the greater prevalence of varicocele upon the left side. The evolutionary factor which has resulted in the superiority of the left cerebral cortex has had, of course, the chief influence in enduing the right side with greater powers than the left. As far as we are aware, no observations have been made as to whether left-handed individuals suffer pain more acutely upon the left side of their bodies, but there is no reason why the sensory as well as the motor conditions should not be reversed in such. Tradition and sentiment have, probably, much to do with this ancient belief. Not only is the left side supposed to be inferior in function to the right, but it has been credited with being of sinister import. The common saying that the individual whose left ear tingles is being spoken evil of would appear to have its origin in great antiquity. Dr. Richard Caton, in the course of the Harveian Oration before the Royal College of Physicians, referred to a passage from an ancient Egyptian papyrus, in which it was stated that the "breath of life" was contained in the right ear, and the "breath of death" in the left. This is,

in all probability, one of the earliest references regarding the common belief in the sinister import of the left side of the body.

#### The Need of a Standard of Purity of Food and Drink.

AT no time up to the present has there been so much activity shown by local authorities in enforcing as far as is legal a high standard of purity of articles sold as food. The administration of the various Acts is, as is well known, in the hands of local bodies, who are, however, as in the case of other matters of public health, under the supervision of the Local Government Board. In a question of public health, however, a local board acts under the direct advice of its medical officer, who is himself in close relation with the medical department of the Local Government Board, which thus establishes a certain uniformity of policy throughout the whole country. As regards food and drink, however, there is no such uniformity of standard of policy. The examination of specimens is in the hands of an analyst, whose duty is limited to reporting on specimens submitted to him. He has no advisory functions, and he is not brought into contact with the Local Government Board, whose control is, under present conditions, entirely nominal. Dr. Louis Parkes, who draws attention (a) to the present unsatisfactory state of affairs, suggests that the Local Government Board should provide themselves with expert advice from a person not only skilled in methods of analysis, but having expert knowledge of the various manufacturing processes employed in the preparation of food and drink. Aided by a staff of trained inspectors, it should be his duty to exercise general supervision, not only over the sale of articles of food, but over their manufacture or importation. He should further lay down standards for the purpose of sale of foods and drugs, and the Local Government Board could thus impose uniform standards on the various local authorities.

#### Latter-Day Recruiting.

THE returns of recruiting given in the lately issued Report of the Army Medical Department for 1902 are of an interesting nature, some incidental light being thrown upon the question of the alleged physical degeneracy of the nation. During the year, out of 87,609 recruits inspected, no less than 26,913, or 30.719 per 1,000, were rejected as unfit. The chief causes of rejection were as follow:—

Defective vision .....	3,437
Disease of heart .....	1,518
Disease of veins .....	1,078
Loss or decay of teeth .....	4,316
Defects of lower extremities .....	1,075
Flat feet .....	1,090
Malformation of chest and spine ..	395
Under height .....	1,015
Under chest measurement .....	4,969
Under weight .....	1,903

The total number of rejections was increased on

(a) *Practitioner*, June, 1904.

that of 1901 by nearly a third, probably in deference to the abandonment of Mr. Brodrick's Army Corps. It is interesting to note that one of the chief causes of rejection was non-existent as a medical test a few years ago, namely, defective teeth.

#### The North of England Miners' Dispute.

THE North of England colliery doctors, as recorded elsewhere in our columns (page 11), have recently formed themselves into a strong and united body under the name of the Northumberland and Newcastle Medical Association. They succeeded in raising fees from the inadequate scale that had been in force for the last sixty years. The miners, however, have resolved to cut down medical remuneration by something like 50 per cent. The matter has now entered the fighting phase. Quite recently the miners have imported medical men, hoping therewith to reduce the established colliery surgeons to terms. It is to be hoped that no medical men will be found willing in the present dispute to accept any such degrading position. Treachery of that kind, unfortunately, is not punishable as "infamous" conduct, but it is certainly regarded with universal detestation and abhorrence by all honourable members of the medical profession.

#### Vaginal Secretions.

THE mystery that attaches to not a few cases of infection of the female genitalia makes of value every contribution to our knowledge of the functions and constitution of the secretions of the various portions of the genital canal. An interesting paper, (a) discussing the question of the possibility of auto-infection in the puerperium, has lately appeared from the pen of Wladimiroff, of the Pasteur Institute. It is now generally agreed the normal vaginal secretion is actively antiseptic in virtue of the lactic acid produced in it by the vagina-bacillus, and as this bacillus is normally present, any stray organisms that may enter the vulva by means of instruments, pessaries, and such agencies generally perish, unless introduced in overwhelming force. The cervical secretion, on the other hand, is sterile, and neutral or alkaline in reaction, so that it forms an admirable culture medium for bacterial growth and activity. Although the vaginal secretion is generally increased as to acidity during pregnancy, during the puerperium all acidity disappears for five or six weeks, and thus it has seemed that the lochial secretions would tend to furnish a ready field for microbic invasion. The wonder would therefore average sojourn being close on four months. Excluding seven cases which were only under treatment for a month, the disease was arrested in twenty-four, and improved in twenty. At present the finances compel the directors to fix the charges at a minimum of £1 per week; but to benefit the working classes, considering that a residence of six months is desirable, they ought to be able to admit at from 5s. to 10s. weekly. This would do much to enhance the usefulness of the institution by inducing cases to come early enough and to stay long enough to have a good chance of being

during the puerperium tend to inhibit and finally destroy pathogenic organisms by phagocytosis, but that bacteria existing in the passages before parturition can gain a foothold in the tissues only if those passages are injured during labour. This explanation, if the right one, will help to clear up a good deal of obscurity.

#### Vermin in Children's Heads.

A NOTE on this subject which appeared in these columns a few weeks ago attracted a good deal of interest among those who have the credit and health of the rising generation at heart. It was pointed out at that time that the present moment afforded an especially favourable opportunity for the new educational authorities to take steps to end the disgrace of having most of the children attending elementary schools infected with head-lice. The Brighton municipal authorities, advised by their able and energetic medical officer, Dr. Newsholme, are never slow in acting up to the level of the best opinion of the day, and one notices with satisfaction that they have taken this matter seriously in hand by appointing a trained nurse in the place of an attendance officer. By this means an instructed and experienced person will be able to visit the children's homes and bring their condition as to cleanliness to the notice of the parents. Although there will be no legal compulsion to make them conform to the advice given, it may safely be assumed that a tactful presentation of the state of things will be pretty generally successful in making the parents ashamed of their delinquencies. The nurse is to act directly under the medical officer, and will assist also in visiting houses when infectious disease has broken out, so that her functions will be manifold. It is to be hoped that Brighton's example will encourage other authorities to go and do likewise.

#### Aids to Dissection.

IT will be generally admitted that a thorough grounding in practical dissection is indispensable for all those who seek to obtain a working knowledge of the way in which the human body is built up. To the surgeon especially an intimate acquaintance with the minute details of anatomy is essential, and hardly less so to the physician. Yet, strangely enough, this is the very part of the medical student's studies most often shirked, the more so in these days of diagrams and photographic illustrations. Dissecting is sometimes irksome, but time spent in laboriously hunting out a minute vessel or in tracing a course of an almost invisible nerve is well spent, for there is nothing like actual use of the knife and forceps to impress anatomical details indelibly upon the memory. Half an hour spent in the dissecting room of a hospital is better than three hours passed, book in hand, in a wax-model museum. However faithfully a part or organ of the body is modelled, the natural colours included, and however realistic

photographic representations of the same may be, they cannot take the place of manual dissection. We notice that a new stereoscopic atlas of human anatomy has recently been published, and while we marvel at the vividness of "parts" portrayed in this fashion, and have nothing but admiration for the excellence of the illustrations, we feel that a word of caution is necessary lest the student should be tempted to trust to these and similar means of acquiring anatomical knowledge instead of going straight to the dead body itself. In their right place such atlases and diagrams may be true "aids" to dissection, but there is a danger lest they should become hindrances by being substituted for individual manual labour in the dissecting room. *Verbum sap.*

#### Disinfection of the Clinical Thermometer.

THE little instrument of precision which is carried about by every medical practitioner, and which alone is the correct guide to the state of the patient's temperature, has often been anathematised by its users. At one time the index cannot be shaken down, while at another it is too fragile or the reading is said to be inaccurate. These supposed faults are, in many instances, due to the manner in which the clinical thermometer is used rather than to the instrument itself. Another charge, however, has a sounder basis, namely, that it is often the medium by which infection is conveyed from one person to another. Like any other apparatus brought into intimate contact with the sick, the thermometer requires most careful disinfection after use. In hospital practice this is most easily and efficiently done, for as soon as the temperature is noted the instrument is at once placed bulb downwards in a small vessel of carbolic lotion, or similar disinfecting fluid. It is notoriously more difficult to carry out antiseptic precautions in private practice, though, happily, it is becoming less so, still, the busy practitioner often has to be content with hastily dipping the bulb of the thermometer in water and wiping it upon a towel or handkerchief, whereupon it is dropped back into its case in a condition which, in the great majority of instances, cannot be said to be aseptic. Many attempts have been made to get over the difficulty, but one of the best is that of putting a few drops of formalin into the case, as was suggested by Dr. W. H. Dyer. That this antiseptic is really powerful in preventing the growth of organisms when employed for this purpose has been recently demonstrated by Dr. F. P. Denny, (a) who has elaborated a series of bacteriological tests, the outcome of which shows that two or three drops of formalin inserted once a fortnight into the thermometer case are quite sufficient to disinfect the bulb and to keep it in a fit state for use.

#### PERSONAL.

MR. G. H. MAKINS presided over a brilliant gathering on the occasion of the South African Civil Surgeons' Dinner at the Hotel Cecil on the 28th ult.

(a) *Boston Med. and Surg. Journ.*, June 2nd, 1904.

THE Earl of Radnor will preside at the Congress of the Royal Institute of Public Health, to be held at Folkestone from July 21st to 26th.

DR. RENEY SMITH is President of the Medico-Psychological Association of Great Britain and Ireland, which meets on July 21st and 22nd at Chandos Street, London.

SIR JOHN WOLFE-BARRY distributes the prizes at King's College, London, this afternoon (July 6th).

DR. JOHN BEDDOE, of Clifton, will deliver the first of the annual lectures instituted at the Bristol Medical School in memory of the late Dr. E. Long Fox.

DR. J. G. DOUGLAS KERR, of Bath, is the owner of the *Valdora*, the winner of the cup in the recent Heligoland yacht race.

SURGEON-LIEUTENANT-COLONEL GASKELL, V.D., J.P. on June 23rd last formally handed over to the Mayor and Corporation of St. Helens the grounds which he has presented to his fellow-citizens, to be known as the Gaskell Park.

THE appointment of Mr. Otho Galgey, M.R.C.P.I., as official member of the Legislative Council of St. Lucia, has been approved by His Majesty the King.

THE Duchess of Albany will open the new ophthalmic out-patient department at the Royal Hospital, Richmond, on July 8th.

DR. J. LORRAIN SMITH, Professor of Pathology in Queen's College, Belfast, has been elected President of the Ulster Medical Society for the ensuing year, 1904-5.

THE Duchess of Albany last week paid a visit to the Royal Hospital for Incurables, Putney, for the purpose of opening the annual sale of work held there for the benefit of the Institution.

PRINCESS CHRISTIAN was present on June 28th at a meeting of the National Health Society, held at the Mansion House, London, and presented certificates and diplomas to those who had been successful in the annual examinations.

THE Duke of Argyll presided on the 28th ult. at a meeting, held by permission of Eleanor Lady Trevelyan, at 67 Eaton Square, S.W., in support of the Metropolitan Provident Medical Association.

SIR CHARLES TUPPER, the veteran ex-Premier of the Dominion of Canada, in his early youth was engaged in medical practice for a short period of his career.

PROF. ROBERT KOCH has been elected a member of the Berlin Academy of Science in succession to the late Prof. Virchow. The *Berliner Tageblatt* states that Prof. Koch has resigned the post of Director of the Berlin Institute for Infectious Diseases.

THE Wightman Lecture of the Society for the Study of Disease in Children will be delivered by Mr. R. Clement Lucas, B.S.LOND., F.R.C.S., at the Victoria Hall, Hotel Cecil, on Friday, July 15th, at 6.30 p.m. The title of the lecture is "The Hereditary Bias and Early Environment in their Relation to the Diseases and Defects of Children." The lecture is open to all members of the medical profession.

Disease of heart	1,518
Disease of veins	1,078
Loss or decay of teeth	4,316
Defects of lower extremities	1,075
Flat feet	1,090
Malformation of chest and spine	395
Under height	1,015
Under chest measurement	4,969
Under weight	1,903

The total number of rejections was increased on

(a) *Practitioner*, June, 1904.

**Special Correspondence.**

[FROM OUR OWN CORRESPONDENTS.]

**SCOTLAND.**

**EPIDEMIC OF SORE THROAT AT BELVEDERE FEVER HOSPITAL.**—During about three weeks of May there was an outbreak of sore throat involving thirty-nine persons, mostly members of the staff, in this hospital. A bacteriological examination showed that in two-thirds of the cases from which swabs from the throat was taken, the organism present was Loeffler's bacillus, sometimes in almost pure culture. The outbreak was clearly due to milk infection, for an organism with the same microscopic and cultural characters was isolated from a sore on the hand of one of the milkers at the farm from which the milk supply of the hospital is obtained.

**TREATMENT OF INFECTIOUS DISEASES AT MONTROSE.**

—In the last annual report of the medical officer of health it is stated that while twenty cases of scarlet fever were removed to the fever hospital, ten of diphtheria and four of typhoid were sent to the infirmary. Dr. Connor explains that the removal of the patients to the latter institution was necessary on account of the skilled nursing required, but points out the desirability of having such arrangements made at the Fever Hospital as would enable him to treat all infectious cases there. In consequence of this report the Local Government Board caused inquiry to be made, and the results of this inquiry, communicated by the secretary, were under the consideration of the Town Council on June 6th, and were remitted to the Public Health Committee. From the strictures of the Local Government Board's medical officer it would seem that a good deal is needed before it can be said that infectious disease is being properly dealt with in Montrose. The person in charge of the Fever Hospital is not a trained nurse, and although many cases of scarlet fever may in their issue prove to have been of little gravity, the local authority ought to fix the standard of attendance to meet the necessities of the grave cases which may occur, not those of the mildest. The arrangements for the treatment of enteric fever and diphtheria in the infirmary are the result of use and are the faulty expedients of bygone days which are totally opposed to present experience. Patients and their friends have, in Sir Henry Littlejohn's opinion, just cause of complaint as to the danger which medical and surgical cases run from their proximity to infectious cases in the wards. A separate ward containing two beds is set apart near the operating theatre for diphtheria cases; this is done for convenience should an operation be needed. For tracheotomy, however, the elaborate arrangements of a modern theatre are unnecessary, and to operate on a dangerous infectious disease in a room filled with all the requirements of modern surgery for the prevention of infection in ordinary operations defeats the purpose of these precautions, and therefore is reprehensible. The Board trust that the local authority, having at present no accommodation for infectious disease, of which the Board can approve, will at once staff and equip the Fever Hospital so as to make it suitable for the proper treatment of all the cases of infectious disease for which they are responsible.

**SIDLAW SANATORIUM, DUNDEE.**—The buildings have now been completed by ex-Provost Moncur's liberality in providing a well-equipped sanatorium at a cost of £25,000. During the first year of the sanatorium's existence, eighty-seven patients were admitted, the average sojourn being close on four months. Excluding seven cases which were only under treatment for a month, the disease was arrested in twenty-four, and improved in twenty. At present the finances compel the directors to fix the charges at a minimum of £1 per week; but to benefit the working classes, considering that a residence of six months is desirable, they ought to be able to admit at from 5s. to 10s. weekly. This would do much to enhance the usefulness of the institution by inducing cases to come early enough and to stay long enough to have a good chance of being

cured. The directors therefore appeal to the wealthy to help them by endowing the sanatorium.

**BELFAST.**

**ULSTER MEDICAL SOCIETY.**—The annual meeting of this society was held on Thursday last in the Medical Institute, Belfast. The President, Dr. John Campbell, F.R.C.S., in the chair. The report of Council moved by Dr. Houston and seconded by Dr. Calwell, showed that the Society is in a very flourishing condition, the total number of Fellows and Members being 197. The report stated that during the past year steps had been taken to procure a bust of the donor of the Institute, Sir William Whitla, and to this end a commission had been given to Miss Kathleen Shaw, who had nearly completed the work. The financial statement was presented, and its adoption moved by the Hon. Treasurer, Dr. W. B. McQuitty, and seconded by Professor Byers. From this it appeared that the annual income of the Society from members' subscriptions is about £300, and that in addition to this several members had contributed special donations amounting in all to £109 to aid in the improvement of the Society's library. The sum expended on books and periodicals during the year was £136. At the close of the financial year a sum of £50 was invested, and a balance of £152 remained in hand. The Hon. Librarian's report was read by the Hon. Secretary, in the absence of Dr. R. R. Leatham, and was seconded by Dr. Nelson. It drew attention to the recent division of the library into consulting and lending departments, the latter being designed largely for the benefit of country members. The following office-bearers for the session 1904-1905 were elected:—President, Professor J. Lorrain Smith; Vice-Presidents, Dr. Hadden (Portadown) and Dr. J. B. Moore (Belfast); Hon. Secretary, Dr. Thos. Houston; Hon. Treasurer, Dr. W. B. McQuitty; Hon. Librarian, Dr. R. R. Leatham; Members of Council (in addition to the seven trustees), Drs. D. P. Gausson, J. R. Davison, J. Hall, D. J. McKinney, J. S. Morrow, and W. L. Storey. Dr. J. C. McCarroll (Carrickfergus) and Dr. William Mair (Queen's College, Belfast) were elected Fellows of the society.

**THE GORDON PORTRAIT.**—At the conclusion of the ordinary business an interesting function took place, a portrait of the late Dr. Gordon, Professor of Surgery in Queen's College, being presented to the society by his daughter, Mrs. Gordon Stallard. In the absence of that lady through illness, the portrait, which was hung in the large hall of the Institute, was unveiled by Mrs. John Campbell. Sir William Whitla, who made the presentation for Mrs. Gordon Stallard, spoke of the suitability of this home for the portrait, where it looked down on so many who had been pupils, and some who had been friends, of the great surgeon and teacher. The President of the Society, in receiving the portrait, said that Dr. Gordon had been not only a member, but also a president of the Society, and on that account, as well as for his world-wide reputation, he welcomed the gift of this portrait. Professor Sinclair, Dr. Gordon's successor in the chair of surgery at Queen's College, moved a vote of thanks to Mrs. Gordon Stallard on behalf of the Ulster Medical Society. Dr. Gordon was, he said, more than a name, even to the younger members of the Society, for the great principles he enunciated have been passed on by his successors. Dr. Gordon's power as a teacher he believed to be due to his rigid self-criticism before laying down any surgical principles. No one who had known him could forget his almost childlike glee over some new observation he had made, and his heart-whole devotion to his profession. Those who had been privileged to know him held him in the warmest esteem and affectionate regard. Dr. Joseph Nelson, as senior trustee, seconded the motion. When a student he had lived as a member of Dr. Gordon's household for two years, so that his knowledge of him was very intimate, and he endorsed all that Professor Sinclair had said. Dr. Henry O'Neill also spoke.

**SMALL-POX IN BELFAST.**—The past week shows some improvement as regards the number of new cases of

small-pox in the city, as only four were found and removed to the Small-pox Hospital at Purdysburn. One of these was the wife of a medical man practising in the Ballymacarrett side of Belfast, who had attended some of the previous cases. The others were all in one house, and will probably be the starting point of further cases, for two unvaccinated children had been ill for a fortnight or more, and it was only when the father also became ill that the facts came to light. There can be little doubt that the people were quite aware of the nature of the disease, and tried to conceal it. One of the cases in hospital died during the week; all the others are doing well. At a meeting of the Belfast Corporation held last week it was stated that the total admissions to the Small-pox Hospital up to date, since the beginning of the outbreak, were 93. There were 55 discharges, 2 deaths, and 36 patients remained in hospital. At the intercepting hospital on the Twin Islands, 302 people had been provided for, of whom 94 still remained, 21 cases having contracted small-pox. At the same meeting Alderman King Kerr, M.D., gave some interesting facts about vaccination and its effects, as seen in this epidemic. In the case of one family, which had been exposed to infection, six were revaccinated and two refused; the six escaped and the two took small-pox. In another case there were 40 contact cases, of whom 39 were revaccinated and one disappeared to avoid it. Later on he reappeared with the disease, the other 39 having escaped! Not a single revaccinated case has been seen at the Purdysburn Hospital.

### Correspondence.

[We do not hold ourselves responsible for the opinions of our Correspondents].

#### SANITARY AND BUILDING BYE-LAWS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—A little space in your influential journal to suggest that our municipal and borough councils make obligatory the use of some kind of approved exhaust ventilator on soil-pipe air-shafts. Whatever the supposed virtue of the wire balloon may have been originally, it is always found to allow "blowdown" at any seaside place or district where gusty winds are frequent. Something better, too, is required than a cowl that merely permits escapement or prevents blowdown, but does not promote an efficient updraught.

Our sanitary bye-laws should also require all closets or bathrooms to be painted. Paper absorbs and retains foul air and is a not unlikely source of infection. Again, ordinary roofs, other than mansards, should be provided with at least one turret ventilator and top floors or landings be ventilated with Tobin tubes. Otherwise the upper parts of the house will receive and retain the exhausted fumes from the kitchen and house generally. An "outlet" ventilator should also be required in the external walls of rooms not provided with a fireplace and an exhaust ventilating shaft to all kitchens, sculleries, bathrooms, and lavatories. These methods are especially necessary at seaside places owing to the difficulty in securing ventilation without draught or disturbance due to the high and variable winds. There is no reason why most of our seaside towns should not rank amongst the healthiest of health resorts if only sanitary regulations of this sort were rigorously enforced.

It is also time that builders and building owners constructed their houses for some definite purpose. An advertisement prior to building, inviting the requirements of prospective buyers or tenants, would be sufficient. At present they build something that may (or may not) suit as a private house; a boarding house, a private hospital, a boarding school, &c., &c., result, dismal discomfort; one or two medium-sized and a large number of small, draughty, wrongly lit, uncomfortable rooms describes most of our modern houses. Whereas if they were built for some definite purpose, adapted to the special needs of the neighbourhood, they would be suited to the requirements of each

case and the occupiers would be comfortable. For example, there are places where boarding houses are in special demand. Or again, places famous for a cure for some particular ailment. Invalid visitors to such places unable to climb stairs, &c., should be provided with ample accommodation on the ground floor. The stock private or residential house cannot meet both of these cases. Our Continental cousins have long since solved this difficulty with the result that each class of visitor is made happy. Our seaside resorts suited to invalids and holiday folk alike would largely benefit by such special structures.

I am, Sir, yours truly,

MODERNUS.

#### ST. GEORGE'S AND HOSPITAL CENTRALISATION.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Your leader of June 29th on the above subject is practical and to the point. You very properly state "there is no poor population close at hand—and domestic servants furnish a considerable proportion of the patients attending the institution." We all know that domestic servants everywhere, more especially the West End of London, enjoy higher wages than ever. Why, then, should a hospital be kept for persons who earn £25 to £40 per annum, besides board and lodging, and most likely never give any contribution to the hospitals whatever? Surely this is an additional instance of hospital abuse. Numbers of people subscribe to the hospitals under the delusion they are helping the very poor, who alone should have the benefit, and yet the pampered menial in receipt of £30 or £40 a year will take advantage of free advice and medicine at the expense of the ignorant philanthropic public who think it a salve to their conscience when about to die to leave their money to hospitals, little knowing how badly it will be applied. It will be a just judgment on selfish hospital boards when your prognostication comes true (as it assuredly will), and the "outer metropolis builds its own hospitals," leaving St. George's and others severely alone.

I am, Sir, your truly,

WEST END.

#### PROPOSED STERILISATION OF CERTAIN DEGENERATES.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—IN THE MEDICAL PRESS AND CIRCULAR of June 29th, a correspondent asks if my proposal to sterilise certain degenerates is "merely academic." Certainly not. All our present efforts to check lunacy and other forms of degeneracy have failed lamentably. The Lunacy Commissioners recognise this. If it were not for the large and increasing number of suicides, we should—even in this country, where new ideas and change are repugnant to nine-tenths of the people—have been compelled to take action. I fear a number of correspondents have failed to read my work. I have given away 360 copies, while it has been published on a purely charitable basis. Those "who have honoured me" (is not this the usual jargon?) by reading it, will note that I refer only to the question of *degenerates begetting offspring*. I do not propose any interference with their marriage even. I only contend that there are certain named degenerates who have no right, moral or social, to curse an offspring with their disease, or to burden the ratepayers by supporting them. In my work, one case is referred to where an imbecile woman was confined of nine children by a partly imbecile father. It has lately been pointed out that in a work-house in Yorkshire five unmarried imbecile women have been confined of fifteen children. And yet even we doctors rant and cant about degeneration, and with an unctuous hypocrisy wonder why these things are allowed to develop. In the same way we allow persons removed from asylums to resume conjugal relations or to marry. Why? Is this the right thing to do? If not, why do we fail to take action? But what can the ordinary medical do when a man of the professional

standing and ability of Dr. Mercier attempts to ridicule the whole question and to switch it off on to the tracts of india ink marks. Surely life is too serious, and the present condition of lunacy too grave to joke about.

I am, Sir, yours truly,  
ROBERT R. RENTOUL.

Liverpool.

#### LUNACY—A PRACTICAL DEFINITION.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—As once a lecturer on legal medicine and induced for various reasons to study legally and clinically the subject of lunacy, I have ventured to draw your attention to it. I cannot agree with Dr. Clement H. Sers that we are sometimes provoked "to shake our fists in the face of any bullying counsel." The way in which I have seen members of my profession refuse to certify in such cases, and far worse ones, as the Archdeacon's brother has impressed me frequently; and I must say that I have always found in a Court of Law a far higher spirit of justice and good feeling among those conducting the legal business than among those engaged on either side, in matters medical. The question that a doctor has to decide when he is called upon to give an opinion on the mental condition of the patient is simply this: Is this person in a condition that frees everyone from responsibility in regard to his actions, and can he be trusted to do no injury to himself or to others by the derangement of mind to which he is temporarily or chronically subject?

If that person has property the lawyer naturally takes greater interest in the case than if he is a pauper. The interests of the patient must be considered on the one hand and the interest of the community in which he lives on the other. We have to distinguish very clearly when we are called upon to certify whose interests have most to be considered. In such a case as the Archdeacon's brother, a lawyer would perhaps take the view that other people can be left to take care of themselves, till crime has brought the lunatic within reach of the law. When we see a poor feeble-minded person who controls valuable property being influenced in an unfair way in the management and disposal of it, we are justified for the good of that person, and in the interests of others, in certifying. The lawyer would be the first to agree with that view, particularly if the patient were a woman. Can this person be treated badly by others, or influenced badly by them? On the other hand, can this person be dangerous to others? These are the simple questions that a doctor ought to be called upon to answer when asked to certify. If he cannot answer, at once and satisfactorily, these questions, he ought to certify accordingly, and let his opinion be handed on to those who can properly deal with it. The doctor has no personal interest in such a case, or ought not to have, and no responsibility. This is all that the law requires, and we need have no fear that a "doctor" will be bullied by a lawyer when he gives his honest and impartial opinion in a case of lunacy.

I am, Sir, yours truly,  
R. L.

### Literature.

#### SQUIRE'S POCKET COMPANION.(a)

THIS is a new book evolved—Phoenix-like—from the ashes of an old and famous volume. It is new in the sense of fresh arrangement and of added and excised matter, but old in the solid familiar outlines of Squire's classical "Companion to the Pharmacopœia" which has outlived several medical generations. The present book has been compiled principally for the use of medical men, and it is the only book of the kind which contains all the official substances together with all the non-official substances which are of any importance, arranged in alphabetical order throughout. The

(a) "Pocket Companion to the British Pharmacopœia." By Peter Wynt Squire. London: J. and A. Churchill, 1904.

apparent exceptions to this arrangement are the grouping of several preparations under one heading, such for example as the new silver salts under "Argenti Nitras," where they can be more conveniently compared than would be the case if they were distributed through the book under the initials of their fancy names. The non-official substances which have not fulfilled original expectations are mentioned collectively in small type under the substance to which they most nearly relate. The paragraphs "Prescribing Notes" originally introduced in the "Companion" have been largely increased both in number and in extent, and add considerably to the value of the book. The solubilities and methods of prescribing are written from the results of actual experiments instituted for that purpose by a special staff that has been engaged upon the work for two years. Other practical notes of a similar nature are also scattered throughout the work, and indeed the guiding principle of utility is everywhere apparent. The references to medical literature are very complete and in one instance that of "Soda-Chlorinatæ Liquor," page 573, A.J.P. 1904, 266 bears the date of June, 1904.

When the preparations official and not official of any substance occupy many pages a saving of time will be effected by reference to the list "Official Preparations" and "Not Official" which are given under the Dose or Prescribing Notes of the principal substance.

As an up-to-date book of ready reference for the consulting room table of any medical man, be he consultant or general practitioner, Squire's "Pocket Companion" would be hard to beat.

#### INFECTIVITY OF ENTERIC FEVER. (a)

IN this octavo pamphlet of forty-seven pages, the writer endeavours to show cause for a revision of our views on the etiology of enteric fever. He tells us that his "aim is to demonstrate that enteric fever is an infectious disease, communicable by direct personal intercourse, just as typhus fever is; and that explanations of its origin from drinking water have, in several instances, failed in the ablest hands." Dr. Collie writes with great clearness and force in support of this thesis. His work is, of course, an iconoclastic attack on a quasi-scientific position which would appear to have been regarded by the great majority of the medical men of one generation as practically impregnable. Under such circumstances we do not consider it our duty to enunciate our own private views in form of an *ex cathedra* opinion; which would almost surely have no other effect than that of adding a new element of discord to a discussion which cannot fail to promote the dissemination of further knowledge, without, at the same time, convincing the holders of either view. Accordingly, we will merely observe that Dr. Collie's facts and arguments show that the defenders of the older position have to deal with a skilled and well-armed opponent. We shall, ourselves, look forward with interest to future revelations and arguments. In the meantime, the increased caution which they tend to promote cannot fail to have a general good effect.

#### STEVENS' PRACTICE OF MEDICINE. (b)

THIS manual, which has been before the profession for many years, is by an American author, and has now reached its sixth edition. The chief object of the book is to present students with an outline of the subject which may be expanded by theoretical and clinical lectures. Bearing this fact in mind, we do not expect to find the work overloaded with details; in fact, the complaint in this country would generally

(a) "The Infectivity of Enteric Fever: with Observations on its Origin and Incidence at Caius College, Cambridge, Festiniog and Wicken Bonant." By Alexander Collie, M.A. Aberd., late Clinical Instructor at the Eastern Hospitals. &c. Bristol: John Wright and Co. 1904.

(b) "A Manual of the Practice of Medicine. Prepared Especially for Students." By A. A. Stevens, A.M., M.D., Professor of Pathology in the Woman's Medical College of Pennsylvania. &c. Sixth Edition, Revised and Enlarged. 10s. 6d. net. Philadelphia and New York: W. B. Saunders and Co. 1903.

be of its brevity, detailed description being, in many parts, inadequate for a student preparing for examination. That this is so may be readily seen by glancing over any of the descriptions of diseased conditions. Thus, rheumatic fever has four pages devoted to its consideration, pulmonary tuberculosis eight, aortic aneurysm three, and alcoholism two respectively. Interspersed throughout the book, however, are numerous simple and useful prescriptions, a feature which will prove very helpful to junior practitioners. Seventy pages are devoted to diseases of the skin, and this is, in our opinion, a wise addition, as we have often had to complain of the absence of their mention in other manuals intended for the use of students. This edition has been carefully revised and enlarged, so that in its new form it really enters upon a fresh lease of life, which, we doubt not, will be a long one.

#### COSTA'S MODERN SURGERY. (a)

THE fourth edition of this book has been revised and brought up to date. In the treatment of the various forms of aneurysm, the author gives in the case of the large arteries, the history of the first operation, then the anatomy of the vessel, and methods of treatment, and finally the results. This section is interesting and complete. In the treatment of tuberculous disease of the hip, when rest and fixation of the joint fail to cure, he recommends the use of intra-articular injections of iodoform and glycerine, saying, "always try these injections before doing a resection," and "it may be necessary to give from ten to twenty injections." As these injections are given once a week this may require a prolonged treatment, and, it seems to us, the risk of such a number of injections would equalise that of resection—we certainly prefer resection as soon as rest and fixation fail. Section XXVII, dealing with "Diseases and Injuries of the Abdomen," is very complete, and the various lesions and operative measures are fully discussed, the various operations on the stomach and intestines being particularly well dealt with. In the section on "Diseases and Injuries of the Rectum and Anus," the treatment of fistula seems to have been overlooked in the revision of the book, for we find no reference to excision and suture of the diseased tract, which method, in suitable cases, greatly shortens the after-treatment. In the treatment of pruritus ani, the author says, "In very severe cases touch with a solution of silver nitrate (1-10), employ the Paquelin cautery, or resect the mucous membrane as in Whitehead's operation for hæmorrhoids." We fail to see how the latter will be of use, as the disease in these cases is entirely outside the mucous membrane. On the whole, this book is complete, pleasant to read, and one of the best single volume surgical works we have come across.

#### NEW BOOKS AND NEW EDITIONS.

THE following have been received since the publication of our last list:—

- EDNEY APPLETON (London).  
Clinical Lectures and Essays on Abdominal and other Subjects. By H. D. Rolleston, M.A., M.D., &c. Pp. 178. Price 5s. net.
- BAILLIÈRE, TINDALL AND COX (London).  
Lectures on Clinical Psychiatry. By Dr. Emil Kraepelin. Authorised Translation from the German, revised and edited by Thomas Johnstone, M.D. Edin., M.R.C.P. Lond. Pp. 308. Price 10s. 6d. net.
- Questions and Answers on Midwifery for Midwives, with Syllabus of Lectures for the "L.O.S." By A. B. Calder, M.B., M.R.C.S. Pp. 143. Price 1s. 6d. net.
- The Prevention of Disease in Armies in the Field. By Robert Caldwell, F.R.C.S., D.P.H., Major R.A.M.C. Illustrated. Pp. 182. Price 5s. net.
- Cleft Palate and Hare-Lip: the Earlier Operation on the Palate. By Edmund Owen, M.B., F.R.C.S. (Medical Monograph Series, No. 10.) Illustrated. Pp. 111. Price 2s. 6d. net.
- Guide to the Analysis of Potable Spirits. By S. Archibald Vasey, F.I.C., F.C.S., Member of the Society of Public Analysts. Pp. 87. Price 3s. 6d. net.
- THOMAS BURLEIGH (London).  
Africa and National Regeneration. By E. F. Chidell. Second Edition. Pp. 78. Price 1s.

(a) "Modern Surgery." By J. Chalmers de Costa, M.D. Fourth Edition, enlarged. Price, 21s. net. Philadelphia: W. B. Saunders and Co.

- J. & A. CHURCHILL (London).  
Uric Acid. An Epitome of the Subject. By Alexander Haig, M.A., M.D. Oxon., F.R.C.P. Pp. 158. Price 2s. 6d. net.
- A Manual of Surgical Diagnosis. By James Berry, B.S., F.R.C.S. Pp. 363. Price 6s. net.
- A Manual and Atlas of Medical Ophthalmoscopy. By Sir William R. Gowers, M.D., F.R.C.P., F.R.S., Fourth Edition edited by the Author and Marcus Gunn, M.B., F.R.C.S. Pp. 318. Price 14s. net.
- The Pocket Companion to the British Pharmacopœia. By Peter Wyatt Squire. Pp. 766. Price 7s. 6d.
- HORACE COX (London).  
The "Queen" Newspaper Book of Travel. A Resumé of the Practical Travel Information that has appeared in the "Queen" from 1894 to 1904. Compiled by the Travel Editor. Pp. 178. Price 2s. 6d.
- C. F. DOWSETT (Basingstoke).  
Buy English Acres. By C. F. Dowsett. Second Edition. Pp. 224. Price 3s. 6d. net.
- THE "ELECTRICIAN" PRINTING & PUBLISHING CO., LTD. (London).  
Radio-Activity. An Elementary Treatise from the Standpoint of the Disintegration Theory. By Fredk. Soddy, M.A. Pp. 214.
- EYRE & SPOTISWOODE (London).  
Army Medical Department Report for the Year 1902. Vol. 44. Pp. 419. Price 1s. 9d.
- WM. GREEN & SONS (Edinburgh).  
Public Health and Preventive Medicine. By C. J. Lewis, M.D., and Andrew Balfour, M.D. Pp. 658.
- CHARLES GRIFFIN & CO., (London).  
A Manual of Ambulance. By J. Scott Riddell, C.M., M.B., M.A. Fifth Edition. Pp. 227. Price 4s.
- A Treatise on Applied Anatomy. By Edward H. Taylor, M.D., F.R.C.S.I. Illustrated. Pp. 738. Price 30s. net.
- KELLY'S DIRECTORIES, LTD. (London).  
Kelly's Directory of Chemists and Druggists, 1904. Tenth Edition. Pp. 740. Price 20s.
- H. K. LEWIS (London).  
The Extra-Pharmacopœia of Martindale and Westcott. Revised by W. Harrison Martindale, Ph.D., F.C.S., and W. Wynn Westcott, M.B. Lond. Eleventh Edition. Pp. 809. Price 9s. 6d. net.
- J. B. LIPPINCOTT CO. (London).  
International Clinics. Edited by A. O. J. Kelly, A.M., M.D., Philadelphia. Vol. I. Fourteenth Series, 1904. Pp. 304.
- LONGMANS, GREEN & CO. (London).  
Wounds in War: The Mechanism of Their Production and Their Treatment. By Surgeon-General W. F. Stevenson, C.B., A.M.S. Second Edition. Illustrated. Pp. 505. Price 15s. net.
- JOHN MURRAY (London).  
Physical Deterioration: Its Causes and the Cure. By A. Watt Smyth. Pp. 318. Price 6s. net.
- YOUNG J. PENTLAND (Edinburgh).  
Manual of Surgery. By A. Thomson, M.D., F.R.C.S. Ed., and Alexander Miles, M.D., F.R.C.S. Ed. Vol. II.—Regional Surgery. Illustrated. Pp. 723.
- The Edinburgh Medical Journal. Edited by G. A. Gibson, M.D., F.R.C.P. Ed., and Alexis Thomson, M.D., F.R.C.S. Ed. New Series. Vol. xv. Pages 575.
- A Manual of Practical Ophthalmology. By George A. Berry, M.B., F.R.C.S. Ed. Illustrated. Pp. 570.
- REBMAN, LTD. (London).  
An Atlas of Human Anatomy for Students and Physicians. By Carl Toldt, M.D., assisted by Prof. A. D. Rosa, M.D. Translated from Third German Edition by M. Eden Paul, M.D. Brux. Fourth Section E.—Splanchnology. Pp. 552. Price 9s. 6d. net.
- W. B. SAUNDERS & CO. (London).  
A Text-book of Clinical Anatomy for Students and Practitioners. By Daniel N. Eisenbrath, A.B., M.D. Illustrated. Pp. 515. Price 21s. net.
- THE SCIENTIFIC PRESS, LTD. (London).  
How to Become a Certified Midwife. By E. L. C. Appel, M.B., B.S., B.Sc. Lond. Pp. 29. Price 1s. net.
- What We Owe to Experiments on Animals. By Stephen Paget. Pp. 72. Price 1s. 6d. net.
- The Case Against Anti-Vivisection. By Stephen Paget. Pp. 104. Price 2s. net.
- Medical Tuberculosis: Its Rational and Natural Cure, its Several Stages, and Relationship to Cancer. By R. B. Searle, L.R.C.P., M.R.C.S. Pp. 40. Price 1s. net.
- SMITH, ELDER & CO. (London).  
Aspects of Social Evolution. First Series—Temperaments. By J. Lionel Taylor, M.R.C.S. Illustrated. Pp. 297. Price 7s. 6d.
- JOHN WRIGHT & CO. (Bristol).  
Acid Autointoxications. By Prof. Dr. Carl von Noorden and Dr. Mohr. Pp. 80. Price 3s. net.
- Golden Rules of Anaesthesia. By R. J. Probyn-Williams, M.D., Pp. 67. Price 1s.

#### Obituary.

ALFRED ELLIS VAUGHAN, L.R.C.P. ED.  
The death is announced of Dr. Alfred Ellis Vaughan, L.R.C.P.E., etc. He was medical officer for the Haslington poor-law district, was surgeon to the Lord Crewe Court of Foresters, and held other public positions. He was educated at Owens College, Edinburgh, and Glasgow, and took the diploma of the Edinburgh Physicians in 1898.

#### Plague Figures.

Up to July 6th, there have been 27 cases of plague among whites and 120 among coloured people. Thirteen whites and 83 coloured people have succumbed to the disease. The last previous statement as to beri-beri showed that there were 40 cases.

## Medical News.

### Annual Meeting of the British Medical Association.

The annual meeting of the Association at Oxford on July 26th, 27th, 28th, and 29th, will be inaugurated by a service in Christ Church Cathedral at 10.30 o'clock, when the sermon will be preached by the Rev. James Franck Bright, D.D., Master of University College. The first general meeting of members will be held on Tuesday, July 26th, at 12 o'clock noon, to be followed by the representative meeting. At 8 o'clock the President, Dr. Collier, will receive the Colonial and foreign guests in the Sheldonian Theatre, and deliver his Presidential Address. On Wednesday, honorary degrees will be conferred in the Sheldonian Theatre, and at 2 o'clock the general meeting will resume its session to consider where the association shall meet in 1905, and to nominate the President-elect. At 8 o'clock Sir William Selby Church, Bart., K.C.B., M.D., D.Sc., will deliver an address in medicine in the Sheldonian Theatre. On Thursday at 2 o'clock, Sir William MacEwen, M.D., F.R.C.S., LL.D., will deliver an address in Surgery in the Sheldonian Theatre. At 7.30 the dinner of the Association will be held in the Hall of Christ Church. At 8 o'clock a popular lecture will be delivered in the Town Hall by Dr. George Bagot Ferguson, F.R.C.S., M.Ch.Oxon. On Friday at 2 o'clock the representative meeting will again sit should it not have completed its work. On Wednesday, Thursday, and Friday from 10 a.m., to 1 p.m., the following fourteen scientific sections, viz., medicine, surgery, obstetrics and gynaecology, state medicine, psychological medicine, pathology, physiology, anatomy, ophthalmology, dermatology, laryngology and otology, tropical diseases, navy, army, and ambulance, dental surgery, will meet in the University Museum Buildings, the work promising to be of special interest. Much hospitality will be offered to members. On Wednesday the President and members of the Oxford Division will hold a reception in Wadham College gardens, while in the evening the Vice-Chancellor and members of Oxford University will give a *soirée* in the Museum. On Thursday there will be garden parties in the afternoon and in the evening an entertainment in New College. On Friday afternoon the Duke of Marlborough will receive a limited number of guests at Blenheim Palace, and in the evening the Mayor of Oxford, Mr. E. A. Bevers, M.R.C.S., will hold a reception in the City Buildings. For Saturday various excursions have been arranged to places of interest round Oxford.

### The Congress of the Royal Institute of Public Health at Folkestone.

THE meeting of the Royal Institute of Public Health will be held at Folkestone from July 21st to 26th, under the presidency of the Right Hon. the Earl of Radnor. Dr. W. J. Simpson and General Sir William Stirling, K.C.B., preside over the sections of Tropical Medicine and the Early Physical Training of the Imperial Forces. Papers will be read and discussed by Mr. James Cantlie, Colonel A. Crombie, C.B., I.M.S. (retired), Brigade-Surgeon-Lieutenant-Colonel W. Hill Climo, A.M.S. (retired), Surgeon-General G. J. H. Evatt, C.B., A.M.S. (retired), and Brigade-Surgeon-Lieutenant-Colonel James Turton, A.M.R. In the section of Comparative Pathology, Bacteriology, and Chemistry Dr. Edward E. Klein, F.R.S., the president, will deal with "The Aim and Scope of Bacteriological Analyses of Water and Shell-fish with Reference to Sewage Pollution."

### The Medico-Psychological Association of Great Britain and Ireland.

DR. R. PERCY SMITH will preside at the sixty-third annual meeting of this association, to be held on July 21st and 22nd, at 11 Chandos Street, Cavendish Square, W. On July 21st, at 2 p.m., the President will deliver his address, after which Dr. G. E. Shuttleworth will read a paper on "The Education and Treatment of Young Epileptics," and Dr. C. Hubert Bond, a paper on "A Plea for the Closer Study of the Bodyweight and its Relation to Mental Disease." On July 22nd, at 10 a.m., papers will be read by Dr. A. W. Campbell

and Dr. John Turner dealing respectively with "Further Histological Studies in the Localisation of Cerebral Function and the Finer Anatomy of the Nervous System with Special Reference to the Doctrine of Continuity." "The Psychology of Hallucinations" will be introduced by Dr. W. H. B. Stoddart. Papers dealing with "The Care and Treatment of the Insane," will be read by Dr. G. M. Robertson, Dr. J. Milson Rhodes, and Mr. J. Carswell, at 2 p.m. On the evening of July 21st, the annual dinner will be held at the Whitehall Rooms of the Hotel Métropole, and on July 22nd, from 4 p.m., to 7 p.m., the President and Mrs. Percy Smith invite members of the Association to a garden party at the Botanical Gardens, Regent's Park, N.W. Tickets for the dinner can be obtained from the honorary secretary, Dr. Robert Jones, price one guinea, including wine.

### A False Certificate.

AT Hampshire Assizes on Saturday, Charles Hustwick was sentenced to eighteen months' hard labour for giving a false certificate as to an infant's death. It was stated accused had acquired some medical knowledge and posed as a doctor. He had previously been sentenced to five years' penal servitude for an illegal operation. He had also adopted a name found in the "Medical Register."

### Small-pox at Stockport.

THE week before last, twenty-one cases of small-pox were reported in Stockport. The majority of the cases were traced to the lower part of the town, where a child was visited by a number of neighbours, whilst suffering from the disease, which was wrongly thought to be measles. St. Paul's Church, Heaton Moor, was closed on Sunday, owing to the apparitor's wife having been attacked by small-pox. The church will be disinfected prior to being reopened. This serious invasion of Stockport is naturally causing a good deal of alarm locally.

## PASS LISTS.

### Trinity College, Dublin.

THE following candidates passed the examinations indicated during Trinity Term, 1904:—

*Anatomy and Institutes of Medicine.*—John C. P. Beatty, Francis R. Coppinger, Robert E. Wright, Thomas J. Cobbe, Thomas H. Peyton, John W. Tomb (*passed on high marks*); Charles T. Atkinson, Richard Connell, Richard G. S. Gregg, Gustav W. Thompson, Theodore C. Somerville, Charles G. Sherlock, Reginald Holmes, Thomas L. de Courcey, Henry D. Drennan, Dudley S. Torrens, Edward, C. Stoney, Herbert J. Wright, Malcolm K. Acheson, William Hutchison, Robert B. Jackson, George E. G. Vickery, Francis Casement, Francis W. H. Bigley, Ernest Jameson, Ernest D. Caddell, Edward Evans, William A. Nicholson.

*Physics and Chemistry.*—Richard P. Hadden (*passed on High Marks*); Charles F. F. Davies, William R. G. Atkins, Ernest C. Lambkin, Dixie P. Clement, Johannes C. Pretorius, Robert V. Dixon, James F. Clarke, Douglas M. Moffatt, Robert G. Orr, William E. Hopkins, Frederick A. Anderson, Gerald McCreedy, Henry H. Ormsby, Samuel F. A. Charles, Norman Jewell, Charles W. Laird, James D. Murphy, John L. Phibbs, Albert V. Richardson, Harold S. Sugars, Richard J. Attridge.

*Botany and Zoology.*—Ralph T. Brooks, Arthur H. Land, Ernest C. Lambkin (*passed on High Marks*); Charles F. F. Davies, Richard P. Hadden, Albert J. Stals, William E. Hopkins, Charles W. Laird, Charles G. S. Baronsfeather, Henry R. Kenny, Johannes C. Pretorius, Dixie P. Clement, Frank N. Smart, Robert E. T. Tatlow, Douglas M. Moffatt, John L. Phibbs, William R. G. Atkins, Thomas P. S. Eves, William Knapp, George H. Stack, James Brereton-Barry, Gordon A. Jackson, Norman Jewell, Alfred H. Smith, Alexander S. Winder, James Beckett, Derrick W. Knight, John T. M'Donnell, Kenneth Smith, Cecil Grene, Frederick C. Newland.

*Diploma in Public Health.*—Parts 1 and 2, Alexander H. Marks.

## Notices to Correspondents, Short Letters, &c.

**CORRESPONDENTS** requiring a reply in this column are particularly requested to make use of a *distinctive Signature or initial*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

**ORIGINAL ARTICLES** or **LETTERS** intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

**CONTRIBUTORS** are kindly requested to send their communications, if resident in England or the Colonies, to the Editor at the London office; if resident in Ireland, to the Dublin office, in order to save time in re-forwarding from office to office. When sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

**SHREWSBURY**.—The original error lay in employing a chemist to take the radiogram of your patient's shoulder instead of a skilled medical operator. A chemist's knowledge of anatomy, both surgical and pathological, is *nil*, and his evidence in a court of law would be worthless. On the other hand the medical X-ray expert is often able to give information that is essential to the proper treatment of a given case and to furnish evidence incontrovertible in a court of law.

**CLIFTONIENSIS**.—Skipping as an aid to health is clearly not available for more than a certain proportion of mankind. You had better consult Dr. Bond, of Gloucester, upon the subject. He is the apostle of this modern cult.

**DR. T. FRENCH**.—The invitation to furnish contributions on special subjects, of a medical nature, to lay journals should be declined in all cases where the object is to provide professional advice with a view to displacing the services of a medical man.

**MR. COOPER JOHNSTON**.—The organisation of a street ambulance system is one that you would do well to take up locally. There is abundant room, nay, an urgent need in most provincial centres for something of the kind. There can be no doubt that a vast amount of human suffering and to some extent of life itself would be prevented if the means of speedy removal of the sick and injured were at hand in all of our great towns. There is a good deal to be said in favour of a co-operation between the philanthropists and the police and the fire brigade services.

**M.R.C.S. (Meltonian)**.—The sea-side is not likely to do any injury to the chronic skin condition you mention. If you have any doubts on the point, send your patient to a consultant.

## Meetings of the Societies, Lectures, &c.

WEDNESDAY, JULY 6th.

**OBSTETRICAL SOCIETY OF LONDON** (20 Hanover Square, W.).—8 p.m. Specimens will be shown by Dr. Lewers, Dr. Purslow, Dr. Sikes, Dr. Tate, Mr. A. Doran and Dr. H. Williamson, Dr. V. Bonney, Dr. Handfield-Jones, Dr. F. Taylor. Short Communication:—Dr. E. Boxall: Case of Inverted Uterus, Spontaneous Re-position. Paper:—Dr. Pembrey (introduced by Dr. A. Kouth) and Mr. G. B. Smith: (In Sacs containing Fœtuses and lying free in the Peritoneal Cavity of a Rabbit.

THURSDAY, JULY 7th.

**THE RONTGEN SOCIETY** (28 Hanover Square).—8.30 p.m. Annual General Meeting. Annual Report and Balance Sheet. Election of Officers for the ensuing year.

**MOUNT VERNON HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST** (7 Fitzroy Square, W.).—5 p.m. Dr. F. Price: The Diagnosis of Early Pulmonary Tuberculosis (illustrated by cases). (Post Graduate Course.)

FRIDAY, JULY 8th.

**OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM** (11 Chandos St., Cavendish Square, W.).—Cases will be shown by Mr. J. E. Smyth and Mr. R. S. Batten. Paper: Mr. G. Coats: Lantern Demonstration on Cases of Thrombosis of the Central Vein.

TUESDAY, JULY 12th.

**THE SOCIETY FOR THE STUDY OF INEBRIETY**.—In the Rooms of The Medical Society of London (11 Chandos Street, W.).—4 p.m. Afternoon Meeting. Dr. William G. Sullivan, Deputy Medical Officer H.M. Prison, Pentonville: On "The Criminal Responsibility of the Alcoholic." Each Member and Associate is at liberty to introduce a visitor.

## Vacancies.

**Brecon and Radnor Asylum, Talgarth, R.S.O.**—Assistant Medical Officer. Salary £100 per annum with furnished apartments, board, attendance, and laundry. Applications to the Medical Superintendent.

**The Royal National Hospital for Consumption and Diseases of the Chest, Ventnor.**—Senior Resident Medical Officer. Salary £300 per annum, with board and lodging in the Hospital. Applications to the Secretary, 34 Craven Street, Charing Cross, London. (See Advt.)

**Nottingham Consumption Sanatorium, Mansfield.**—Resident Medical Officer. Salary £150 per annum, with board, lodging, and washing. Applications to the Clerk, Mr. Geo. Sheldon, 36A Bridlesmith Gate, Nottingham.

**Combined Sanitary District of West Sussex.**—Medical Officer of Health. Salary £250 per annum, to include all travelling expenses. Applications to A. C. Coole, Solicitor, 9 Carlisle, Horsham.

**East London Hospital for Children and Dispensary for Women, Shadwell, E.**—Pathologist and Registrar. Salary £100 per annum. Applications to Thomas Hayes, Secretary.

**Gravesend Hospital.**—House Surgeon. Salary £100 per annum, with board and residence. Applications to F. H. Stevens, Hon. Secretary, 146 Milton Road, Gravesend.

**Hereford County and City Asylum.**—Senior Assistant Medical Officer. Salary £150 per annum, with board, lodging, and laundry. Applications to the Medical Superintendent.

**London Temperance Hospital, Hampstead Road, N.W.**—Resident Medical Officer. Salary £200 per annum, board, lodging, and washing. Applications to A. W. Bodger, Secretary.

**Metropolitan Asylums Board, Darent, Dartford, Kent.**—Male Assistant Medical Officer. Salary £150 per annum, with rations, lodging, attendance, and washing. Applications to the Office of the Board, Embankment, London, E.C.

**New Zealand—Seacliffe Lunatic Asylum, Dunedin.**—Assistant Medical Officer. Salary £250 per annum, with board, lodging, and washing. Applications to the Agent-General for New Zealand, 13 Victoria Street, London, S.W.

**Nottingham General Dispensary.**—Assistant Resident Surgeon. Salary £180 per annum, with furnished apartments, attendance, light, and fuel. Applications to Secretary, M. I. Preston, Journal Chambers, Nottingham.

**Royal National Hospital for Consumption and Diseases of the Chest, Ventnor.**—Two Assistant Resident Medical Officers. Salary £100 per annum, with board and lodging in the Hospital. Applications to the Secretary, 24 Craven Street, Charing Cross, London, W.C. (See Advt.)

**Royal Orthopedic Hospital, Temporary premises, 55 Bolsover Street, W.**—House Surgeon and Registrar. Salary £200 per annum, without board. Applications to Tate S. Mansford, Secretary. (See Advt.)

**St. Thomas's Hospital.**—Casualty Officer. Salary £100 per annum, with board and residence. Application to the Secretary of the Medical School.

**Wandsworth Union Infirmary, St. John's Hill, near Clapham Junction.**—Junior Assistant Medical Officer. Salary £100 per annum, with board, lodging, and washing. Applications to Medical Superintendent.

**West Riding Asylum, Wakefield.**—Pathologist and Assistant Medical Officer. Salary £140 per annum, with furnished apartments, board, washing and attendance. Applications to the Medical Director.

## Appointments.

**GRAY, WALTER GORDON, L.R.C.P., L.M. Edin., M.R.C.S.,** Medical Officer of Health for the Holworthy (Devon) Rural District.

**KEENAN, J. F.,** of Ballinalee, Edgeworthstown, as Certifying Surgeon under the Factory and Workshop Act for the district of Ballinalee, which includes Granard Urban District and Granard No. 1 Rural District.

**MEADE, CHARLES GRAHAM, L.S.A.,** Medical Officer for the Witherside District by the South Molton (Devon) Board of Guardians.

**PALMER, FREDERICK S., M.D., M.R.C.P.,** Assistant Physician to the West End Hospital for Diseases of the Nervous System.

**PARSONS, JOHN HERBERT, B.S., D.Sc., F.R.C.S.,** Ophthalmic Surgeon to the Hospital for Sick Children, Great Ormond Street.

**PRICE, H. VAGUHAN, F.R.C.S. Eng., M.A., M.B., B.C. Cantab.,** Honorary Medical Officer to the Brighton, Hove, and Preston Dispensary.

**RICHARDS, THOMAS, L.R.C.P. Lond., M.R.C.S.,** District Medical Officer by the Cardiff Board of Guardians.

**SHORT, T. SYDNEY, M.D. Lond., M.R.C.P., D.P.H. Cantab.,** Honorary Physician to the General Hospital, Birmingham.

**SIMPSON, LILLIAN G., M.D. Brux., L.R.C.P. & S. Edin.,** Senior Resident Medical Officer to the Canning Town Medical Mission Hospital and Dispensary.

**WILLIAMS, W., M.A., M.D. Oxon.,** Examiner in Preventive Medicine in the University of Oxford.

## Births.

**DARE-BASCOMBE.**—On June 26th, at the Grange, Saffron Walden, Essex, Edith (nee Hastings-Miller), the wife of C. Dare-Bascombe, M.R.C.S., L.R.C.P., of a son.

**MICHELIS.**—On July 2, at 48 Finsbury Square, the wife of E. Michels, F.R.C.S., of a daughter.

**SECKER WALKER.**—On June 29th at Oakwood Grange, Roundhay, Leeds, the wife of H. Secker Walker, F.R.C.S., of a son.

**WIGG.**—On July 1st, at 86 Haverstock Hill, N.W., the wife of James Wigg, L.R.C.P. Lond., of a son.

## Marriages.

**MORTON—LESLIE.**—On July 1st, at St. Stephen's Church, Putney, Philip Sidney, son of Robert Morton, Esq., of 27 Hamilton Terrace, N.W., to Philadelphia Fraser Pinkerton, youngest daughter of the late W. Burnup Leslie, Esq., M.D., of Stonehaven, N.B., and of Mrs. Leslie, 40 Oakhill Road, Putney, S.W.

## Deaths.

**KIRKMAN.**—On July 1st, at St. Stephen's, Southwold, Suffolk, Joshua Kirkman, M.A., late vicar of St. Stephen's, Hampstead, and eldest surviving son of John Kirkman, M.D., of Melton, Woodbridge, aged 75.

**LEPPER.**—On June 26, suddenly, at Southsea, George R. Leeper, M.B., T.C.D., third surviving son of the late Rev. Canon Leeper, D.D., Dublin.

**MURPHY.**—On June 28th, at 5 Thornhill Crescent, Sunderland, the residence of her son, Sarah Murphy, widow of William Chapman Murphy, M.D., aged 90.

### THE DIMINISHING BIRTH-RATE.

#### PART I.

By DAVID WALSH, M.D. Edin.,

Senior Physician, Western Skin Hospital, London, W., &c.

THE Inaugural Address of the British Gynæcological Society for the year 1904 discussed the diminishing birth-rate of the United Kingdom, together with "its Causes, Tendency, and Possible Remedy." It was delivered by the distinguished President, Dr. John W. Taylor, of Birmingham, whose remarks have excited widespread interest among all classes of society. Although its subject is by no means purely medical, yet matters of such vital social importance are dealt with that no apology need be offered for presenting a short criticism of Dr. Taylor's arguments and conclusions in the columns of a medical journal.

Dr. Taylor rightly said that his subject was a great one. In spite of that recognition, however, he has surveyed the situation almost entirely from a single standpoint, namely, that of the assumed evils resulting from the artificial prevention of conception. By thus narrowing the field of inquiry he has failed to bring the many sides of an extremely complex social question into view. As a matter of fact, his Address is little more than a plausible but not very convincing piece of special pleading against the unfortunate practices to which he attributes so much of the moral and physical defects of society. The causes and results of the limitation of families, however, must be examined under a far more searching and catholic light than that provided by Dr. Taylor. Many of the issues involved may be discussed entirely apart from either the practices of prevention or the crime of abortion, both of which the moral citizen must unhesitatingly condemn. Nevertheless, however great our desire to place society on a sound footing, if we accept theories and assumptions offhand we may find our well-meant efforts diverted into a Quixotic tilting against windmills.

Dr. Taylor's general statement that the birth-rate of the United Kingdom is steadily declining may be accepted. He shows that the birth-rate has fallen 5.2 per 1,000 persons living during the past thirty years, while the marriage-rate has remained practically stationary. From that point forward, however, his article contains hardly a single proposition that will stand serious examination. His chief assumptions with regard to the falling birth-rate appear to be as follows:—

I.—That the fall in the birth-rate refers solely to married persons.

II.—That among married folk the decline is due almost entirely to the artificial prevention of conception.

III.—That a falling birth-rate necessarily indicates a failure in national prosperity.

IV.—His main conclusion, or, from my point of view, assumption, is that preventive practices are

injurious to the moral and physical well-being of parents adopting them, as well as to non-prevented children of such unions.

In the present brief article I propose, as a medical man, first to examine the above assumptions, and to ask if they tally with the facts of the case; then to discuss the proposed remedies; and, finally, to add a few observations and suggestions of my own. An attempt will at the same time be made to indicate the broad lines on which a comprehensive survey of the ground might with advantage be conducted, although I cannot hope that every side of this intricate question will be exhausted or even opened up.

*Assumption I: That the fall in the birth-rate refers solely to married persons.*—As already remarked, Dr. Taylor's proposition may be admitted when he says that the birth-rate has fallen 5.2 per 1,000 persons living during the past thirty years, while the marriage-rate has been nearly stationary. But when he goes on to infer that the fall in question must be due to some condition affecting married life, he at once plunges into a morass. His figures have not taken into consideration the obvious extra-marital condition of illegitimacy, the results of which are included in the general birth-rate of 5.2. Now, a striking feature of the period he covers is the decrease in the number of illegitimate births in the United Kingdom, for they share in the steady fall from 6.8 per cent. to 3.9 per cent. of the total births during the past fifty years. If this loss of 2.9 per cent. of illegitimate births had not occurred the level of the general rate would stand at the present moment not far off the level of twenty years ago. This may be made clear by the following figures:—

TABLE I.

Illegitimate rate per 1,000 births 20 years ago ..	68
Ditto ditto ditto at present ..	39

Loss from decreased illegitimate births per 1,000 births ..	29
---	----

Present total birth-rate per 1,000 persons living, 29.1.

But if no loss had occurred from the decline in illegitimacy, this rate would have increased in proportion of  $\frac{1,029}{1,000}$

Working this out, we get—

$$29.1 \times \frac{1,029}{1,000} = 29.94 \text{ (or nearly 30),}$$

as the total birth-rate would be at the present moment had there been no falling off in illegitimacy. But in 1884 the total birth-rate stood at 31, so that had not the declining birth-rate affected illegitimacy, we should have had a birth-rate of practically 30 in 1904 compared with 31 in 1884. My figures, I am aware, may not be absolutely accurate, but I think it may be safely concluded that the fall in the married birth-rate is much less than that shown by Dr. Taylor. In a word, his figures are vitiated at the outset by his failure to consider the facts of the extra-marital condition of illegitimacy.

It is impossible, therefore, to accept his fundamental

proposition that "we may take the birth-loss in the United Kingdom as due to causes operating in the married life of its inhabitants."

*Assumption II: That among married folk the decline is due almost entirely to the artificial prevention of conception.*—Before examining the grounds upon which Dr. Taylor forms this conclusion, or assumption, as I prefer to call it in the absence of convincing proof, let us first consider another vitiating factor, namely, the increasingly later age at which marriages take place. True, he mentions this condition, but only to brush it aside somewhat cavalierly in his anxiety to reach his main conclusion. It deserves, in my opinion, far greater weight than he is inclined to attach to it. The age at which a man marries has, or should have, within reasonable limits, but little effect on the prospect of his becoming a father, for if of sound constitution he may beget children at ninety or any other patriarchal age. The average life of civilised man, however, is comparatively short, and hence the influence of late marriage upon fertility is appreciable. One cannot lose sight of the fact, moreover, that a man who marries, say, at thirty-five has already lost some twenty years of active procreative life had he been living under unrestricted conditions. But when the marriage age of woman is taken into account we find a very different state of things. In her case the number of years during which she may expect to become a mother is strictly limited, and decreases with every year of her life until about five-and-forty, the fall in marriage fertility being specially noticeable after twenty-five. Now, as a matter of fact, the age at which women marry in the United Kingdom is becoming rapidly later, for whereas the period 1894-1901 shows a 6 per cent. increase of population, yet, on the other hand, the total number of women marrying under twenty years of age decreased by nearly 300, instead of the increase of many thousands that would have taken place had these under-age marriages continued in their former proportion. These figures are all the more remarkable if compared with the increase of over 32,000 marriages of women between twenty and forty during the same period.

We find, then, that marriage is becoming later in both sexes, a fact that in itself connotes a lessened expectation of children, because the parents' lives are shorter, while procreative power slackens with advancing age in the male and ceases altogether with middle age in the female. The later age at which men marry is doubtless due to the increased difficulty of gaining a footing in life, especially in the learned professions. Men who marry thus later in life are likely, as a broad rule, to marry women of an age somewhat approaching their own, and with correspondingly lessened expectation of child-bearing life, a fact that is well shown in the following table, which was placed before the Royal Statistical Society by Dr. Ogle, in March, 1890:—

TABLE II.  
AGE AT MARRIAGE.

Occupation.	Bachelors.	Spinsters.
Miners .. .. .	24.06	22.46
Textile trades .. .	24.38	23.13
Shoemakers and tailors .. .	24.92	24.31
Artisans .. . . .	25.35	23.70
Labourers .. . . .	25.56	23.66
Commercial clerks .. . . .	26.25	24.43
Shopkeepers and shopmen .. .	26.67	24.22
Farmers and sons .. . . .	29.23	26.91
Professional and independent class .. .	31.22	26.40

This table shows a close relationship between the class of society to which persons belong and the age at which they marry—the better the social circumstances the later the marriage age. The general disparity is most striking when we compare the extremes, which show a difference of seven years in the case of the men and four in that of the women. The marriage age of unskilled labourers is probably much below that of miners and other skilled labourers. The marriage age, again, of such learned professions as that of law and medicine is, most likely, some years beyond that of all professional and independent classes taken together.

If we allow, say, a further margin of four years for unskilled labour at one end of the scale and four years for the learned professions at the other, we have a difference of fifteen years in their respective marriage ages.

The increasing mean age of marriage is well shown in the following tables drawn up in 1874 by Mr. Ansell:

TABLE III.  
RATE OF MORTALITY, LONDON, 1874.  
Period of Marriage.

Years.	Mean Age at Marriage.	Mean Difference in Ages.	
	Bachelors.	Spinsters.	
Before 1840 .. .. .	28.64	24.75	3.89
Since 1840 (to 1874) .. .	29.95	25.53	4.42
Both periods .. .. .	29.31	25.16	4.16

TABLE IV.

Date.	Mean Age at Marriage.	Mean Difference in Ages.	
	Bachelors.	Spinsters.	
1800	27.89	24.30	3.59
1810	28.89	24.52	3.74
1820	28.64	24.74	3.90
1830	29.01	29.94	4.05
1840	29.39	25.1	4.20
1850	29.76	25.41	4.35
1860	30.14	25.64	4.50
1870	30.51	25.84	4.65

The later age of marriage, then, is a factor of prime importance in the decrease of a birth-rate. Taking it along with the fall in the illegitimate birth-rate, we find two conditions sufficient in themselves to account for a good deal—if not the greater part—of the decrease in the general birth-rate of the United Kingdom which furnishes the basis of Dr. Taylor's investigations. The assumed fall of 5.6 in the total married birth-rate is a bubble that collapses when we subtract the illegitimate births. The assumed cause of the decline in the birth-rate of married persons, namely, artificial prevention, collapses also when we apply the test of the later marriage age. Increased continence is not considered worthy of discussion as a possible influence in the decline, either legitimate or illegitimate.

It is clear, therefore, that if Dr. Taylor's foundations are thus insecure, the walls of his superstructure will have little chance of surviving. However, in order to arrive at a basis of argument, we will return to our common point of agreement, that is to say, the admitted fall of 5.6 in the total birth-rate of 1,000 persons living. Similar conditions, it seems reasonable to assume, will ultimately affect the birth-rate both of married and unmarried persons. For instance, if the lessened number of illegitimate births may be ascribed to a generally higher standard of sexual morality, there is no apparent reason why a similar continence should not limit the offspring of married life; or, assuming with Dr. Taylor that artificial prevention is the main cause of limitation, the practice is likely to affect child bearing as regards unmarried women not less than married women.

Dr. Taylor quotes the following figures as the average yearly number of births per 1,000 persons living in Great Britain and Ireland during the

TABLE V.

F.ve-yearly periods.	Birth-rate per 1,000.
1874—1878	34.3
1879—1883	32.6
1884—1888	31.2
1889—1893	29.8
1894—1898	29.1

But he has chosen twenty-five years of steady decline. If he had included the thirty years before 1874 he would have found a period of steady increase. In England alone the birth-rate from 1838—1841 was 31.97 per 1,000 population. (a) For the United Kingdom I have not been able to obtain the exact average rate, but it would be somewhere roughly about 30. So that the birth-rate of 1900 has practically reverted to that of 1840. During the sixty years that intervened there was a steady increase for nearly thirty years to a maximum (36.3 in 1876), and then a steady fall for

(a) "Fifth Annual Report of Registrar-General in England, 1843."

thirty years to a minimum and somewhat lower figure than that of 1840. Dr. Taylor says the fall is due to artificial prevention of conception, which he carefully states is a new condition introduced within the last thirty-five years. To what does he attribute the increase? Why, again, does the birth-rate of 1840, before artificial prevention was in vogue, stand practically at the same figure as that of 1900? Clearly, by his own account, prevention had nothing to do with the average birth-rate of 30 in the year 1840. It is just as necessary for Dr. Taylor to find an explanation for the figures of 1840 as those of 1900. The figures that he would have us believe are of such terrific import in 1900 must surely have had their significance in 1840.

Is it not possible that the birth-rate has waxed and waned during the latter half of the nineteenth century in obedience to economic laws? We know, for instance, that the marriage-rate varies exactly with the activity of trade, and the number of births has a close relationship with the general prosperity. We know, moreover, that as the result of free trade, the last century witnessed a vast increase in the national wealth, as well as its more equal distribution in the shape of wages and income. May not the increase and decrease of the birth-rate be regarded as a delicate index of the general prosperity, not only as regards the actual amount of wealth in the country, but as to its just and equitable distribution? The decline in the birth-rate of 1900 may possibly point to an approaching limit of population under present social conditions.

The facts of the case may be conveniently illustrated by taking the particular instance of the Borough of Islington, with an estimated population for 1903 of 339,197 persons. The picture reproduces in miniature the main features of the national birth-rate, and has been carefully dealt with by the able medical officer of health, Dr. Alfred E. Harris. The later marriage age of woman is shown in the following table:— (a)

TABLE VI.

SHOWING THE PROPORTION OF MARRIED WOMEN AT FOUR PERIODS OF THEIR CHILD-BEARING AGES, IN EVERY 1,000 OF SUCH MARRIED WOMEN.

Age Periods.	Census Years.		Increase or Decrease.
	1891.	1901.	
15—20 .. ..	8.14	6.36	— 1.78
20—25 .. ..	133.05	124.69	— 8.36
25—35 .. ..	468.94	481.99	+ 13.05
35—45 .. ..	389.87	386.96	— 2.91

The next table brings out clearly the fact that although the number of women capable of bearing children had largely increased, yet the number of children borne by them had largely decreased. So far as the births among unmarried women are concerned, a decrease of 20.2 per cent. in the birth-rate is recorded.

TABLE VII.

	1,000.00		Increase or Decrease.
	1889-93.	1899-'03.	
Average number of unmarried women and widows at child-bearing ages .. ..	45.032	47.711	+ 2,689
Average number of married women at child-bearing ages .. ..	39.152	42.598	+ 3,446
Births per 1,000 unmarried women and widows at child-bearing ages .. ..	6.61	5.28	— 1.33
Births per 1,000 married women at child-bearing ages .. ..	237.6	211.3	— 26.3
Number of births among unmarried women and widows at child-bearing ages .. ..	1,488	1,258	— 230
Number of births among married women at child-bearing ages .. ..	46,524	45,015	— 1,509

(a) "48th Annual Report of the Borough of Islington," 1904.

The illegitimate births registered in Islington between 1851 and 1900 were in ten-yearly periods:—

TABLE VIII.

Periods.	Illegitimate Births.
1851—1860	1,335
1861—1870	2,651
1871—1880	2,429
1881—1890	3,475
1891—1900	2,710

The birth-rates of Islington from 1841 to 1903 were:—

TABLE IX.

Periods.	Birth-rate.
1841—1850	28.65
1851—1860	34.54
1861—1870	37.20
1871—1880	36.60
1881—1890	32.56
1891—1900	29.11
1901	27.62
1902	26.80
1903	26.48

During the sixty years covered by the ten-yearly periods, the birth-rate rose to a maximum about its middle, while the figures at the beginning and the end nearly coincide.

Dr. Taylor advances no facts in support of his assertion that artificial prevention of conception is the main cause of the decline in the birth-rate. Most medical men receive the confidence of patients in sexual matters, and they would probably admit that such practices are increasingly prevalent among the better-off classes of the United Kingdom. They would probably agree, also, in questioning prevention as the main cause of the falling birth-rate, principally on account of the futile character of the means employed. Such methods are usually adopted by those in whom continence is not a virtue, and breakdowns in the arrangements occur often enough to nullify the gross effect of most of the precautions. On the contrary, how often does one meet with the opposite state of mind—a desire for children which Nature denies? Admit that artificial prevention is increasing among the wealthier classes, Dr. Taylor would have to prove, in order to maintain his position, that a corresponding decrease in the birth-rate has not affected the birth-rate of the poorer classes. He had made no attempt—not even by the royal road of assertion—to show that artificial prevention is practised to any extent among the poor.

(To be concluded.)

## A CRITICISM OF THE MOSQUITO THEORY OF INFECTION

### IN MALARIA AND YELLOW FEVER.

By DR. L. CHEINISSE,

Ex-Interne of the Hospitals of Montpellier.

[SPECIALLY REPORTED FOR THIS JOURNAL.]

To raise the question of the importance of the mosquito in respect of the infection of malaria and yellow fever will no doubt savour of audacity to many, but I propose to do so in deference to Montaigne's maxim that "when a new doctrine is put forward we have every reason to look askance at it." Indeed, it is impossible not to feel a lurking scepticism in view of the enthusiasm with which this novel theory has been everywhere accepted. When, some fifty years ago, J. C. Nott promulgated the theory that mosquitoes were instrumental in conveying the infection of yellow fever, he little thought that one day his hypothesis would become the *credo* of epidemiology, not only in respect of *vomito negro*, but of other infective diseases. *Habent sibi fata*. Suspected by Nott and elaborated by Finlay, the theory of the transmission of yellow fever by mosquitoes elicited no echo, and it had fallen into oblivion when the researches of certain English and Italian observers on the rôle of the mosquito in

propagating malaria directed attention to this factor of contagion. "The mosquito," writes M. Bard, "introduced into the domain of pathology by the filaria, soon aspired to a wider field of usefulness, and at present yellow fever is in part its work, while malarial fever is its predilection." But this writer is too modest in describing the rôle of the mosquito in yellow fever as "partly" accounting for infection. Things have reached such a pass that it is impossible to conceive the contagious character of *typhus amaril* without invoking the assistance of the *Stygomyia fasciata*. According to present views quarantine is unnecessary, nay, even a person suffering from the disease cannot transmit it in the absence of the mosquito link of the chain. The American Cuban Commission is equally emphatic on this point, so that the prophylaxis of yellow fever is reduced to the simple aphorism: *Vitandi culices, delendi culices*.

In support of this view we are referred specially to the observations of American pathologists on the inoculation of yellow fever by mosquitoes. Apart from the fact that these observations are open to criticism it is worthy of note that they leave the exact nature of the poison a matter of doubt. The parasites of the *Stygomyia fasciata* comprise fungi, ferments and sporozoa, but none of these has any bearing on yellow fever.

The etiological similarity between malaria and yellow fever, so often invoked in favour of current views, obviously falls to the ground. For the analogy to be complete it would be necessary to admit, in regard to yellow fever, the existence of a specific hæmatozoön which, like that of malaria, has its evolution in two different hosts. As M. Bandi remarks, it would be strange if this problematic hæmatozoön could pass one phase of its existence in the organism of an insect without the latter exhibiting the slightest trace of this cellular parasite. From this point of view the mosquito theory, as applied to malaria, is much more satisfactory. The description of an invisible germ ingested with contaminated blood, which for twelve days undergoes some obscure change in the body of the *Stygomyia*, hardly commands acceptance. Moreover, it is especially by analogy that the theory of the transmission by mosquitoes has been extended to yellow fever. The moment is opportune to ask ourselves to what extent this theory falls into line with the facts even in respect of malaria, a question that has been infinitely better studied than the problem of *typhus amaril*.

The transmission to man of the malarial poison by the anopheles is, we must admit, based on a considerable number of duly observed facts. The infective rôle of this insect has been experimentally established, and the life history of Laveran's hæmatozoön, with its two phases, the asexual reproduction in the human blood and the sexual generation inside the body of the mosquito, is well known. But does that justify the assumption that the infection of the human being by the insect and that of the insect by man constitute the complete cycle? In other words, is the mosquito bite an indispensable formality before man can become infected with malaria? Can we really affirm that in the absence of the mosquito there is no risk of contracting malaria?

I do not propose to discuss *seriatim* all the arguments that have been brought forward in support of the mosquito theory, especially as many of them have already been refuted. (a) Moreover, their importance varies greatly, many of them having been advanced merely to bolster up the theory, and, therefore, do not deserve attention. It is obviously impossible to admit that the comparative immunity of the aborigines of hot climates is due to the thickness of their skins and to the pronounced odour which scares away the mosquito, since filariasis—also transmitted by culicidæ—is commoner among the black than among the white population.

(a) See "La Théorie des Moustiques est-elle Univoque?" *Navarre. Lyon Med.*, November, 1900.

Instead of discussing at length arguments of this class, I prefer to bring together a certain number of facts which, far from confirming the rôle of the anopheles as the sole agent of transmission of malaria, tend rather to throw doubt upon the existence of any constant relationship between any kind of mosquito and malarial infection.

First of all the geographical distribution of the anopheles by no means corresponds to the distribution of malaria. This insect abounds in certain regions whence malaria has quite disappeared, or has never existed. It may be objected that the most important fact to take into consideration is the numerical distribution of the insects in question. But even from this point of view the theory fails, for, according to Dr. Sargent, they are far more numerous on the banks of the Essonne, where malaria is almost unknown, than in certain admittedly malarial districts near Algiers. Dr. Sargent is therefore obliged to explain the disappearance of malaria on the banks of the Essonne by invoking other factors—drainage, &c. In any case, it is obvious that there is no sort of parallelism between the presence and number of anopheles and the existence of malaria. We shall be told, of course, that the anopheles is only dangerous as a vehicle for the transmission of the virus, and that in the absence of infected subjects the insect is harmless. But, apart from the fact that this does not explain the disappearance of malaria from districts once infected where the anopheles continues to abound, the theory is one which M. Celli himself admits is not without exceptions, since he mentions districts where, though malaria is rife and the anopheles numerous, new-comers are not infected. M. de Francesco, on the other hand, points to districts deeply infested with malaria where no anopheles has been seen. He consequently protests against the dogmatism which declares this insect to be the sole agent in the propagation of malaria. If the anopheles can do this thing, why not the *Culex pipiens*? It is true that he did not succeed in discovering in the intestines and salivary glands of the latter the ovoid and the spermoid of the hæmatozoön, nor the zygotes which is the outcome of their conjunction, but is it not well known to be unnecessary for the hæmatozoön of malaria to traverse the body of another being to be enabled to convey the poison of malaria?

It is not enough, indeed, to admit that the anopheles has no monopoly in this respect as the partisans of the theory would have us believe. The truth is that malaria can be propagated without the intervention of a mosquito of any sort. Epidemics of the kind have already been described, as, for instance, after heavy rains (Canton of Lourmel, Algeria). Dr. Gros remarks, in reference to this outbreak, that he had done his best to discover some specimens of anopheles, but had utterly failed, although the local conditions were distinctly favourable to their development. Mosquito bites may certainly serve as the front-door for the entrance of the malarial poison, but there are certainly other means of penetration. Even if an insect of some kind be regarded as indispensable to the transmission, it is not necessarily or always the anopheles.

I will now adduce some epidemiological observations more to the point. Taking the sanitary returns of the Prussian army, Dr. Grawitz made graphic records of the prevalence of malaria in the 1st and 4th Corps, the regiments most subject thereto. Now malarial infection is very general from the onset of spring, that is to say, at a season when, in Eastern Prussia and Posen, mosquito bites must be extremely rare. On the other hand, during July and August the incidence of the disease falls quite suddenly, although the men are at that time most discomforted by mosquito bites.

Dr. Muller, a Russian army medical officer, has studied the co-relationship of mosquito bites and malaria for three years in Bessarabia, a region where malaria is endemic. In the three years in question

the proportion per thousand of men attacked by malaria was as follows:—

	1899.	1900.	1901.
May .. ..	3'78	4'45	3'93
June .. ..	5'90	2'91	5'81
July .. ..	3'24	4'81	9'80
August.. ..	3'44	7'56	11'22

With respect to the mosquitoes, he states that they were altogether wanting in 1899, while in 1900 they abounded in these districts; in 1901 there were but few, and they almost disappeared in August, which happened to be cold. More than this, in June, 1900, the proportion of soldiers infected was only one-half that in 1899. Lastly, during the third year, when mosquitoes were rare, the sickness remained at about the same figure as in 1899 for the first two months, then, in July, without any perceptible increase in the number of mosquitoes, it increased considerably, and in the following month, at a time when the mosquitoes had disappeared altogether, the percentage reached a height never before attained. In short, apart from the month of May, the malarial sickness during 1901 was throughout twice as great as the previous year, which was particularly rich in mosquitoes.

It would be difficult to allege a more flagrant discrepancy between the presence of mosquitoes and the prevalence of malaria. If, on the other hand, we bear in mind the other factors, such as temperature, atmospheric moisture, the rainfall, &c., it is seen that the oscillations recorded on the charts correspond to these meteorological or telluric influences.

Dr. Kourlov's observation at Tomsk, in Siberia, are not less conclusive. Malarial infection usually commences to make itself felt in March, at a time when the earth is still covered with snow, and the thermometer marks about 10° C. below zero, conditions hardly favourable to the existence of mosquitoes. It attains its maximum in April, yet there was on an average twenty-seven days under freezing point, and the average temperature was 1.2° C. below zero. According to Dr. Vender, who carried out his observations in another Siberian town, Kolyvan, malaria commences, as at Tomsk, in March, and since the disease is propagated during March and April without the intervention of the mosquito, we are entitled to ask whether these really play such an active part in its dissemination.

However this may be, it is evident that the mosquito cannot be regarded as the sole agent of the transmission of the disease. This being so, it becomes us to exhibit a certain reserve before accepting the triumphant narratives of protection against malaria by gauze shutters. Although the very antiquity of the telluric theory is against it, we need not fear to hold, with Dr. Bard, that the improvement is to be attributed rather to improvements in the soil than to the destruction of the larvæ of mosquitoes.

If this be the case in respect of malaria the greater must be our reserve when it is sought to extend the theory to yellow fever. It is purely a case of reasoning by analogy; indeed, we are asked to believe in "the presence of hæmatozoa, as in malaria, which, moreover, offers the closest resemblance to yellow fever." These hypothetical hæmatozoa of yellow fever cannot for the time being be otherwise described than as presenting a certain resemblance with the "animalculæ" described by Athanasius Kircher and von Leeuwenhoek as being at the root of all epidemic maladies. It really seems as if, in the words of an eminent English observer, "the reign of the bacteria has attained its apogee, and that of the hæmatozoa is now about to begin."

No doubt the results of experimental inoculations of yellow fever by mosquitoes are extremely suggestive, but as Dr. Berenger-Feraud points out, the disease thus inoculated may not improbably be inflammatory bilious fever, i.e., a relatively mild form of yellow fever. This view is endorsed by Dr. Mendonça, who feels certain that the disease observed by Finlay and by American observers at Cuba and Sao Paulo was, in reality, the inflammatory fever of the Antilles. The only really characteristic experiments are those

carried out by Dr. Guiteras at the Havana Hospital, in which the typical symptoms were present, and the diagnosis was verified post-mortem. But, unfortunately for their conclusions, it is precisely the experiments carried out at Havana that gave positive results, while those of Reed, Carroll, and Agramonte failed to demonstrate the truth of the new hypothesis.

Without discussing in detail the conclusions of the American Cuban Commission, I submit that we can in no wise attribute the disappearance of yellow fever at Havana to measures taken for the destruction of mosquitoes. Dr. Souchon, basing his conclusions on the statistics of yellow fever since 1817, points out that the disease usually wears itself out in from two to four years, unless revived by fresh cases imported from outside, whence it follows that quarantine and the disinfection of merchandise are necessary measures. Moreover, Dr. Souchon states that the number of mosquitoes has not apparently diminished in Havana. Dr. Andrade reports several instances of places in Brazil where the authorities succeeded in stamping out yellow fever before the mosquito theory had been invented. On the other hand, the destruction of mosquitoes at Sao Paulo and neighbouring localities does not, so far, appear to have had any influence on the prevalence of the disease.

In 1901 Dr. Purnell published a series of observations on the transmission of yellow fever by infected fomites, and he points out that the lapse of time between the original cases and the subsequent infection was too great to allow it to be possible to incriminate the mosquito. He himself attributes but trifling importance to the part played by the mosquito in the dissemination of yellow fever. The history of the great epidemic at Grand Bassam in 1902 is specially conclusive from this point of view. This place had on several occasions witnessed outbreaks of the disease, and the last epidemic was in 1899, since which date no cases presented themselves, until, on July 19th and 20th, 1902, some well-marked cases occurred. In 1899 cases had occurred in pretty well all the houses of Bassam, and in one house five out of six died. Near this house was a pool of brackish water into which the dejections and soiled effects of the victims were thrown in 1899. The medical authorities had long demanded the filling in of this pool, and in July, 1902, steps were taken with this object in view. Now, all the persons attacked by yellow fever in 1902 lived in the neighbourhood of this pool, or had close relations with those who did. It follows that contaminated objects are capable of transmitting the disease, even after three years—that is to say, long after the infected mosquitoes must have perished, even if we credit them with extraordinary longevity.

Before deciding that the prophylactic measures hitherto enforced are absurd, it behoves us to think twice, for at present it seems a bold thing to contend that the whole prophylaxis of yellow fever consists "in preventing the *Stygomysia fasciata* from biting the healthy after biting the sick."

## THE CRIMINAL RESPONSIBILITY OF THE ALCOHOLIC. (a)

By WILLIAM C. SULLIVAN, M.D.,  
Deputy Medical Officer, H.M. Prison, Pentonville.

THE author made allusion to the fact that the legal responsibility of the alcoholic had already been the subject of discussion by the Society, and in this connection the names of Dr. Crothers and of Dr. Norman Kerr were specially to be remembered.

He remarked that when we speak of alcoholic

(a) Abstract of a Paper read before the Society for the Study of Inebriety, at the Rooms of the Medical Society of London, Tuesday, July 12th, 1904.

crime we generally have in mind homicidal offences, for, though alcohol leads to other forms of delinquency, it is in murder that its influence is most evident; in this country, at all events, it is the most important individual cause of that crime. In discussing legal responsibility, it will be practically convenient to adopt the same attitude, and to limit our observations to cases of homicide.

In such cases the question of responsibility arises in connection with three conditions:—(i) Chronic alcoholic insanity; (ii) delirium tremens; and (iii) the dreamy mental state of morbid drunkenness.

In the first-named condition the question is decided by the same criteria that are admitted in non-alcoholic insanity, so that its consideration need not detain us. Similarly, cases of distinct delirium tremens present no special difficulty. It is when we come to cases of alcoholic automatism, to crimes committed in the dream states of pathological drunkenness, that we meet with differences in opinion and practice, the condition being sometimes held of no account, sometimes admitted as an extenuating circumstance, and sometimes treated as equivalent to legal insanity. On this account, and because these cases constitute the large majority of alcoholic crimes, it is desirable to devote special attention to them, and they are accordingly suggested as the special subject of this discussion.

The objection to recognising alcoholic automatism as a morbid condition modifying legal responsibility appears to rest chiefly on the fear that there would be therein some risk of abuse; any criminal, it is said, would only need to get drunk in order to secure immunity from his misdeeds. Those who entertain this fear, however, do not take account of the fact that the automatism of the alcoholic is really a very definite condition as to its character and as to its causation. Of course, an element of automatism belongs even to the common phenomena of drunkenness, but it is only when the symptom has become very much exaggerated in degree that we have the dream states here considered, with their tendencies to criminal conduct. *And this exaggeration occurs only in neuropathic subjects.* Most commonly this neuropathic predisposition is due to chronic alcoholism; what ordinarily happens, in fact, is this—after many years of intoxication marked by symptoms of common drunkenness, the individual acquires a peculiar susceptibility to alcohol, so that relatively small doses lead to more or less lengthy dream-states, in which the patient may seem to speak and act pretty coherently, though in reality he is in a sort of somnambulistic state and knows nothing at all afterwards of what he has done, or has only a hazy recollection of it; in one of these phases he will probably murder his family, or attempt suicide. Besides chronic intoxication, which is the most frequent cause, other conditions also predispose to automatism under alcohol, and of these epilepsy, head injury, and insane hereditary taint are the most important.

It is this constant relation to a definite neuropathic disposition that is the most distinctive and important fact about alcoholic automatism, and the recognition of this fact should go far to dispose of the fear that the admission of irresponsibility in such cases would lead to abuse. No

one becomes mad when drunk who is wholly sane when sober.

Regarding the condition of memory in these cases, it is to be noted that the amnesia is often incomplete, and also that its development may be delayed, so that there may be a clearer recollection of the crime immediately after the dream phase than at a later period.

In connection with the general demeanour of the automatic drunkard, much interest attaches to a recent observation of von Gudden, who has found that in about half the cases of this condition with irritability of temper, there is impairment of the light reflex, lasting as long as the dreamy state persists. This may possibly prove a valuable medico-legal test.

The admission of morbid drunkenness as a condition excluding full responsibility is especially desirable in that it would further the trend of public opinion to adopt preventive measures against the criminal alcoholic. It is, in fact, mainly as a means of eliminating potential criminals that the institutional treatment of ordinary drunkards is of use to the community. When, therefore, the chronic alcoholic has once shown the disposition to dream states with impulsive tendencies, especially homicidal or suicidal, he ought to be dealt with on the same footing as the impulsive epileptic—immune from ordinary punishment, but unfit for ordinary freedom.

## THE VESTIGES OF SYPHILIS.

By FRANK H. BARENDT, M.D. Lond., F.R.C.S.,  
Senior Physician, St. George's Hospital for Diseases of the Skin;  
Consulting Dermatologist Royal Southern Hospital, Liverpool.

It frequently happens that the question of syphilis arises in connection with the disease from which the patient is suffering. As a correct answer is of supreme importance in treatment, it occurred to me that a short account of those imprints that may be left behind by the disease would be of general interest.

I need not allude at length to the numerous diseases which may arouse in our minds a suspicion of previous syphilis. It is well known that many anomalous nerve affections—eye, ear, nose, throat, and cutaneous troubles, &c.—often suggest syphilis as an etiological factor. It therefore behoves us to make use of all the knowledge of this far-reaching disease that we have in the excellent clinical observations that have been handed down to us by syphilographers of former days.

With regard to inherited syphilis, the Hutchinsonian triad is now universally accepted as an indication of congenital syphilis, and all of us recognise its value. The condition of all the permanent teeth is important, and a careful examination of the molars should not be omitted. These are often dome-shaped, due to the imperfect development of the cusps, and present consequently smaller grinding surfaces than normal. This condition of the molars has remained well marked in cases where the notches in the incisor teeth have lost their striking character through attrition.

Are there any signs, more or less permanent, upon which we can rely as evidence of syphilis which the patient may have acquired years ago? At the outset, we can ask the patient the leading question, to which we may get a correct answer; but the nature of the disease, the method of infection, the evanescent memory of early lapses from right conduct, all combine to render the:

patient prone to oblivion of such an event in his life, especially if unmarked by his having had to seek medical advice. Even when an unwilling admission is extracted, it frequently happens that he glosses it over with a smoothness that makes his cross-examiner wonder whether his suspicions are not after all ill-founded; and that, in his desire to clutch at some definite cause, he may wrongly appraise the diagnostic value of the statements of his patient.

Far be it from me to malign any special calling, but I cannot help thinking that if the patient is, or has been, a sailor or soldier, or one whose business takes him frequently from home, these occupations bring greater liability to the infection of syphilis than any other in this country. Another point I should lay stress upon is the abuse of alcohol in the early adult life, for there is no doubt that syphilis has often been acquired when the control of the higher senses is impaired.

As regards the nature of the initial lesion, I venture to think that too much value is attached to the absence of a sore, be it soft or hard, on the penis, and too little to the history of what our patients call a "simple running." It is a matter of common knowledge that the famous John Hunter, from an experiment on his own body, largely retarded our progress by confounding syphilis and gonorrhoea, and ascribing them to the same contagium. His error has been explained by the supposition that he inoculated himself with the discharge from a urethral chancre, and that the discharge mistaken by him for gonorrhoea was due to the concealed chancre. I have carefully read the history of this famous experiment, and feel that such an acute observer as he undoubtedly was could scarcely have overlooked the presence of a urethral chancre. I venture to suggest that the disease with which he inoculated himself was actually syphilitic urethritis. That syphilis may produce urethritis is admitted by all competent recent syphilologists, and, like syphilitic colitis, is due to the presence of syphilides in the mucosa. We admit the infectivity of mucous patches in the mouth and throat, and therefore the simple running, as the phrase goes, taken together with the anomalous disease the patient at the time of our examination presents, may turn out to have been a true syphilitic urethritis, and represent the primary stage of infection. At any rate we must not exclude all possibility of syphilis because there is no history of sore or of skin troubles, and only one of simple running.

*Syphilis d'emblee* of French syphilographers, where the initial effect is not demonstrable, can thus be explained, the site of the initial infection being intra-urethral, of the nature of a mucous patch, and unnoticed by the patient. The same holds good for balanoposthitis, for it is well known that the desquamating papule—one type of the initial sore of syphilis—may be masked by a profuse secretion due to balanitis and posthitis. Extra-genital infection should not be forgotten; and although infrequent in this country, suspicious depressed stellate scars, in the absence of a satisfactory history of trauma, should put us on our guard. Digital infection is by no means so rare as is generally supposed, and is not only confined to medical men and midwives.

A few remarks may not be out of place with regard to secondary syphilis, *i.e.*, the presence of syphilides of the skin and mucosæ as far as these can be inspected during life. It is well known how

unobservant many patients are of skin eruptions, especially when they are not pronounced and unaccompanied by itching. We should remember that women infected by their husbands frequently never have and give no history of a secondary eruption, especially when pregnancy occurs about the time of infection. As far as my experience goes, I have seen secondary syphilis most frequently in women who are not and have never been pregnant; but in those who are parous and indubitably have contracted syphilis in their early married life, it has been rare to get a history of cutaneous and mucosal eruptions, although one of frequent abortions is common enough. In both sexes a history of piles should not make us forget the possibility of their being condylomata.

Of the vestiges left by antecedent syphilis, no one by itself is pathognomonic; and such as they are, they must be carefully weighed together with the nature and history of the disease for which the patient seeks our advice. One of the most important is a scar, depressed, irregularly marginate, and occupying a region of the body not liable to injury in ordinary pursuits, and where history of injury is excluded. If such scars are multiple the suspicion is strengthened; and if in addition there is a disturbance of pigmentation giving rise to map-like configuration, the explanation should be very satisfactory indeed from the patient if we are to abolish from our minds the idea of syphilis. The presence of a scar on the penis is of value; whether a soft sore produced it or a hard one has, or ought to have, little weight with us when we suspect syphilis. Far too much has been made of this character as a diagnostic criterion; and although most writers admit of the two types of sores, yet a soft sore may be the site of the inoculation of syphilis, just as a hard sore may be but a local ulceration due either to a specific bacillus (Ducrey) or to pus organisms. The multiplicity of a sore is no proof at all of its being simple in its nature; and when in Vienna I saw multiple hard chancres, two being on the left index finger, one on the corona, and two on the body of the penis. In my experience, whenever a patient admits having had a chancre, the scar can be discerned on careful examination of the site even when several years have elapsed since infection. Herpes preputialis may leave scars, especially after recurrent attacks, but here we have no loss of substance to the same extent that obtains in chancres.

Syphilis has been termed big-pox in contradistinction to variola or small-pox. Pustular syphilides are at present among the least frequent of secondary eruptions, and such is the experience of Continental observers. I myself have only seen one case where the secondary eruption was stated to be pustular, and at first glance I mistook the condition for a previous attack of small-pox. The pocks were deeper and whiter, and the immediate surrounding integument was much more pigmented, but the pitted face looked very like that produced by small-pox. There was, however, abundant evidence of the disease being syphilitic, quite apart from the patient's statement.

Scars in the sural and peroneal regions, although the legs are more liable to injury than other members, are always suspicious. On the front of the shins the evidence is of little value, for most of us have had some injury inflicted upon them at some time or another. Pigmentation in this region is frequently seen in women who have a penchant

for warming this part of their anatomy, and must not be wrongly interpreted. It constitutes the "ephelides ab igne" of authors, and when well developed may lead to mistakes in diagnosis.

Eruptions on the palms and soles are suggestive, especially when they take the form of discrete papules surrounded by a scaly ring, *papules en collerette*, as French dermatologists call them. In examining the skin, and especially the hands and feet, for such vestiges, the patient should be warm, otherwise the natural mottling of the skin—the so-called *cutis marmorata*—may interfere with our correct appreciation of such eruptions.

Leucoderma is an important change, and when present is a valuable sign of previous syphilis. It is due to circumscribed loss of normal pigment, whereby white spots are formed, surrounded by pigmented rings which shade off into the normal colour of the skin. Such spots of leucoderma may develop in the site of former efflorescences, be these early or late syphilides. They persist for a long time, are most often seen on the nape of and sides of neck, and are apparently more frequent among women than men. I can testify to the value of this important cutaneous change, and have frequently found it confirm the suspicion of syphilis. The affection may assume figured patches, and the marked pigmented border helps to distinguish it from leucoderma which may arise in the course of malignant disease. In all cases of suspected syphilis, I would urge the careful inspection of the neck, especially for white spots surrounded with pigment rings—standing out in marked contrast to the neighbouring skin. This can readily be done without drawing too much attention.

Generally speaking, syphilides are essentially pigment disturbers, and therefore any mottling or discoloration of the skin should be taken note of in determining the question of previous syphilis. Gentle pressure by a microscopic slide will expel the blood from the subjacent capillaries, and thus render the pigmentation more readily manifest.

White scars in the *rosa* of the lips are of great value, especially if these are at the angles of the mouth. The mucosa should be most carefully inspected, more particularly the inner surface of the cheeks; fine irregular and opalescent streaks are always suggestive and persist for a long time after other manifestations of syphilis have passed away. Any marked loss of submucous tissue causing depression of the mucosa is, in the absence of any history of traumatism, most suspicious.

Many authors lay stress on enlargement of nuchal glands as persisting long after cutaneous and mucosal syphilides have disappeared. In my experience I rarely have found such a condition, although it is common enough for these glands to share in the general adenopathy that accompanies the secondary period.

But there is one site in women where syphilides linger longest, and that is at the junction of the hairy scalp and nape of neck, just as in men in the temporal region. These areas should always be inspected for traces of syphilides. The long persistence of seborrhoeic eruptions should always suggest a possible syphilitic basis.

The eyes should always be examined for the Argyll-Robertson sign (loss of pupil reflex to light, with the power for accommodation unimpaired). This sign when present should always arouse a suspicion of previous syphilis being the cause, even when no other nerve lesion is manifest.

I believe that these vestiges constitute irrefutable proof of acquired syphilis, and should ever be present in the mind of the examiner when this question arises. I have endeavoured to guard myself from being too dogmatic, and I repeat that there is not one of these points taken by itself that may not be capable of another interpretation. On the other hand, when we meet with two or more—e.g., scars and pigmented areas with no history of trauma, I think we are perfectly justified in placing a patient who is suffering from some disease of which the etiology is veiled, tentatively at least, on antisiphilitic treatment.

## Clinical Records.

### A SERIES OF CASES OF PUERPERAL INFECTION TREATED BY THE INTRA-UTERINE APPLICATION OF IODISED GAUZE.

Under the Care of E. CABANES, M.D.,  
Chef de Clinique at the School of Medicine of Algiers.

For some time past I have treated every case of puerperal infection that has come under my care by a novel procedure which has yielded such uniformly satisfactory results that the notes of some of the more recent cases may not be without interest. Briefly described, the treatment comprises the removal of any fragments of placenta or membranes, by the aid of the blunt curette if necessary, followed by irrigation with an antiseptic solution. The next step is to introduce into the uterine cavity a strip of gauze steeped in an aqueous solution of iodine and iodide of potassium, 4 per cent. of each. The strip is only loosely packed, and when the cavity has been filled a vaginal douche is given and a plug of iodoform gauze placed in contact with the cervix to absorb any leakage of iodine, thus avoiding injury to the vagina. The dressing may advantageously be renewed every twelve hours so long as there is the slightest rise of temperature, but marked benefit usually follows the very first dressing. The treatment, moreover, is applicable as well to recent cases as to cases of old standing. The presence of peri-uterine inflammation is no bar to its performance; indeed, it is indicated in all cases of uterine infection, at all stages and under all conditions.

**CASE I. Puerperal Septicæmia of twenty days' standing.**—Madame S., multipara, became feverish soon after delivery of a child at term. Eight days later (January 5th) medical advice was obtained, and the uterus was washed out twice daily with boiled water, in spite of which the temperature continued to oscillate between 99° and 103.8° F. Irrigations with sublimate solution were then substituted, but the disease continued to run its course unchecked, and the patient fell into a state of intense prostration, with severe rigors and exhausting sweats. On the 15th, her temperature was 104° F., and the pulse 150 per minute. Her condition was alarming in the extreme. The first iodised dressing was then introduced, and on the following day the temperature was almost normal. The dressings, however, were renewed twice daily, and by the 18th the temperature had returned to normal, the pulse being 96. This case is noteworthy in that the dressing gave an immediate result, although the infection was of twenty days' standing. Nine dressings were applied in all before the temperature finally returned to normal.

**CASE II. Puerperal Septicæmia.**—Madame O., primipara, was delivered of twins on February 5th, having been attended by the same midwife as the patient in the preceding case. In the meantime, this midwife had infected several other parturients, two of whom succumbed to the disease. Things went on all right for the first ten days, when the patient was seized with fever, and her pulse rose to 24 per minute. On the 16th the temperature rose to 105° F., and she had severe rigors. The vulva and cervix were covered with a diphtheroid exudation, and there was a discharge of pus from the os uteri. After the application of the

iodised dressing the temperature fell to 99° F. and the pulse to 100. On the 17th, it rose again, but after two more dressings it fell permanently to normal. After the 19th only antiseptic injections were employed.

CASE III.—Miss X., primipara, was confined on March 12th. Her temperature became irregular on the 19th, and Dr. Vincent was called in consultation. On the 20th, although her temperature was only 99° F., the pulse was 120, and she had just had two severe rigors. There was a rather extensive laceration of the cervix, and the lochia were somewhat offensive. Blood-stained pus could be seen escaping from the os uteri. The patient was curetted and in the course of the ensuing twenty-four hours two iodised dressings were introduced. An hour after the curettage she had another violent rigor, during which the pulse-rate rose to 130 per minute; but on the 20th, after a third dressing, the temperature fell to and remained normal. The patient was discharged cured a fortnight after the onset of the illness.

CASE IV.—Miss P., the subject of syphilis, had aborted for the third time as the result of an illegal operation at two and a half months. She had been ill for a week, but as her temperature continued to rise she reluctantly called in a doctor. She was evidently gravely infected, and the vaginal discharge was intensely foetid. She was admitted to hospital, where the uterus was immediately curetted and the iodised dressing applied. The temperature was only 99°, but she developed symptoms of pelvi-peritonitis, which continued to run its course, although on the third day all disagreeable odour had disappeared from the vaginal discharge. She ultimately developed pyosalpinx, which gradually and slowly became encysted, the uterus remaining embedded in a mass of fibrous adhesions. The constitutional infection found expression in a pulmonary infarct and a metastatic abscess in the right rectus abdominis muscle, in spite of which she recovered. One is fain to ask what her fate would have been if the uterus had not been thoroughly aseptically. This case is particularly interesting in that it proves the utility of the treatment even in cases in which the infection has extended beyond the limits of the uterus. Although the dressing does not, of course, hinder the evolution of the peri-uterine complications, it at any rate removes the original, and also the central, focus of infection, and in so doing it must unquestionably tend to modify the course of the collateral infective manifestations.

*Conclusions.*—The results obtained in every case of puerperal infection which has come under my observation since I began this treatment appear to me to justify the following conclusions, viz., (1) that the iodised dressing can be applied repeatedly without the slightest risk to the infected uterus; (2) it should be applied every twelve hours in order to make sure of obtaining prompt and certain effects; (3) its repeated application cuts short the attack of puerperal endometritis within a few hours; (4) it may determine recovery even in advanced cases; and (5) it is also applicable to cases of generalised septicæmia, although complicated by peritonitis, in that it removes the central focus of infection, although in such cases its curative influence is necessarily reduced.

### Transactions of Societies.

#### NORTH-EAST LONDON CLINICAL SOCIETY.

The annual meeting of this Society was held at the Tottenham Hospital, N., on Thursday, July 7th, 1904, the President, Dr. J. W. HUNT, being in the Chair. The Council's Report for the last session showed that much good work had been done, many valuable communications having been made in the shape of papers, while the Clinical Cases and pathological specimens exhibited at the meetings had been both abundant and of more than usual interest.

The report having been adopted, the ballot for officers for the ensuing session then took place with the following result:—*President*, Dr. R. Murray Leslie. *Hon.*

*Treasurer*, Dr. A. E. Giles. *Hon. Librarian*, Dr. A. J. Whiting. *Hon. Secretaries*, Messrs. H. W. Carson and C. E. Hutt. The Vice-Presidents and Council were also elected in accordance with the recommendation of the Council.

The meeting then resolved itself into a garden-party held in the beautiful and picturesque grounds of the hospital (by kind permission of the Board), and which was well attended by members and their friends.

### British Health Resorts.—I.

[BY OUR SPECIAL MEDICAL COMMISSIONER.]

#### SIDMOUTH.

SIDMOUTH forms an ideal south-country resort. It is situated in East Devon between the Rivers Exe and Axe, in the well-wooded Vale of Sid. Early in the nineteenth century it had gained a position as a desirable health station, and although of recent years it has been overshadowed by the rapid growth of other western resorts, it now bids fair to gain distinction among the places offering special attractions to the invalid and the health-seeker. The town, quiet and picturesque, and free from the barbarities of the modern, tripper-frequented watering-place, lies wedge-shaped in a horse-shoe valley. While open on the south to the sea it is protected on the west and east by red sandstone cliffs, which form the seaward limits of the protecting, wooded and green-pastured hills. The town is thus shielded from the winds most trying to the invalid, and yet so placed as to allow of the maximum exposure to the sun. The soil is dry and porous. The natural vegetation of the place is abundant, and well attests the mildness of the climatic conditions and richness of the land. The grassy, tree-covered slopes, and the richly wooded and high-hedged lanes, secure ample shelter and protection for the invalid. The hillsides and sloping valley form admirable ground for the carrying out of graduated exercise, while the pleasing, old-fashioned sea front provides a fair extent of level ground for bath-chair cases and those needing a restful exposure in the open. For the active, there are the Salcombe and Peak cliffs close at hand, the breeze-blown tops of which may be gained by a not too steep ascent of about 500 feet. On these airy uplands there is ample opportunity for vigorous exercise amidst picturesque surroundings, and with far-reaching views of sea-coast and undulating inland country.

Sidmouth enjoys much sunlight. In winter, there is said to be more sunshine than in most of our other south coast resorts; while in summer it is claimed that there is considerable protection from excessive glare. As regards the temperature, Sidmouth is warm in winter and not unduly hot in summer. The average of the winter minima is nearly two degrees above that of London, and the average of the winter maxima 17° above that of the metropolis. During 1903, the mean temperature of the year was 50.1°, and the average mean of the last thirty-two years, 49.61°. The mean daily range was for the last twenty-four years 8.6°. It is interesting here to note that during the great summer heat of 1899, the mean temperature of the month of August at Sidmouth was 63.3° (the highest register during the previous thirty years), and, notwithstanding this, it was from ten to twenty degrees cooler than London, and five degrees below that of any other health resort on the south coast during the greater part of the month. Sidmouth may rightly claim to possess a peculiarly equable climate, cool in summer and mild in winter. The absence of sudden change of temperature goes far to make the place a particularly suitable residence for convalescents, invalids, delicate children, adults of feeble constitution, and the aged. It may be here added that frost and snow are almost unknown, and fog is rare. Thunderstorms are also infrequent.

Devonshire is generally recognised as a rainy county, but at Sidmouth the rainfall is comparatively low, and is said to be 36 per cent. below that of the rest of the

county. This is doubtless due to the fact that the surrounding hills waylay the rain-laden clouds, while the high ground of Dartmoor precipitates much of the moisture brought by the west winds from the Atlantic. The rainfall for 1903 was 36.39 inches, which is 5.77 inches above the last twenty years' average (30.62 inches). The relative humidity is returned at 83, and well indicates the prevalence of desirable conditions for the invalid. As already indicated, the natural position of the town affords admirable protection from winds most trying to the feeble. The funnel-like form of the Vale of Sid doubtless in part accounts for the prevalence of invigorating breezes, which fortunately free Sidmouth from the relaxing and enervating characters of certain of our well-known southern resorts.

While Nature has been kind, man, in his control of the district, has been wise. There are no artificial attractions offered to the mere frivolous visitor. The sea-front is spoiled by no pier or unsightly pavilion, and even the railway station lies a good mile inland. If Sidmouth is to continue to grow in favour with both physician and patient, it will be well that its natural simplicity be preserved. Excellent accommodation is provided in several well-appointed hotels. Particular mention should be made of the new Victoria Hotel, situated within sight and sound of the sea, and yet surrounded by trees, at the western end of the front. The hotel has been excellently designed, and is perfect, not only in hygienic equipment but in all that makes for comfort and even luxury. Certain suites have been so arranged as to allow of an open-air treatment of any invalid residents. The number of private apartments in the town is limited. Sidmouth is also provided with well-designed baths, where Aix and Nauheim treatments, in addition to the usual complement of sea and fresh-water baths, are carried out, under the conduct of an experienced manager, as we have had personal opportunities of ascertaining. Adjoining the baths is a well-conducted club, open to visitors.

On the hillside, at the western end of the town, are attractive golf links. The hill slopes in the immediate neighbourhood of the town should prove peculiarly attractive to those of delicate health desiring a permanent country and sea coast residence. There is a fairly good drainage system, and the water supply is of exceptional quality and non-irritating to the skin. The town is clean and well lit. For the robust there are ample facilities for sea-bathing and the shore is safe for children. Sidmouth is a perfect resort for the convalescent, the chronic invalid, and the aged and all requiring the benefits of a "rest cure," and such climatic conditions as are associated with an equable and not too relaxing marine residence.

Catarrhal and cardiac forms of asthma are said to do well at Sidmouth. The baths offer means for the trustworthy treatment of judiciously-selected cardiac and rheumatic cases. Certain forms of neurasthenia should also gain much benefit, and for the recreation of the over-worked brain labourer and the rejuvenescence of the jaded victim of society, Sidmouth has much to offer.

A well-illustrated official guide has been published under the auspices of the Sidmouth Urban District Council, and interesting booklets have been issued concerning the baths. The excellent health reports of Dr. Pullin, the Medical Officer of Health, may also be studied with advantage. Sidmouth is 167 miles from London on the L.S.W. Railway, and may be easily reached from Waterloo Station in about four and a half hours.

## Continental Health Resorts.

[FROM OUR SPECIAL CORRESPONDENT.]

### AIX-LA-CHAPELLE (AACHEN).

THE celebrated hot-springs here are regaining, slowly, perhaps, but steadily, some of their former pre-eminence among German mineral-water resorts. The

vigorous advertising of some of the newer spas has gained for them fame in recent years; and, comparatively, the number of annual visitors to the older Continental health-stations has not increased proportionally to the respective merits of the waters. Aachen, however, can yet challenge comparison for its highly valuable springs, the elegance of its accommodation, and its city conveniences with any of its more energetic and youthful competitors.

In selecting a place of sojourn for a "cure" continuing several weeks, the advantages of a town residence merit attention. As a city of over 126,000 inhabitants, Aix-la-Chapelle has these; and, added to them, many local and antiquarian attractions. Its hotels, pensions, and apartment-houses are numerous and at all prices. Amongst them, the Hôtel Grand Monarque is deservedly popular with British and Americans for its up-to-date comforts, good table, and attendance.

The mineral springs are numerous, both in the town and the vicinity, and are used for drinking as well as external applications. They are prescribed for a variety of diseases, especially for gout, strictures, and rheumatism.

## France.

[FROM OUR OWN CORRESPONDENT.]

PARIS, July 16th, 1904.

### BACKACHE.

BACKACHE, says Dr. Fiessinger, belongs to divers affections. It is a symptom of very unequal value, as it is met with in the most benign as well as in the gravest maladies. It is for the practitioner to discover the nature of the pain. A patient comes to consult him for a pain in the back and asks to be relieved, and how will he set about it?

The principal seats of the pain are two—the dorsal and the lumbar region. In the former, the pain is generally to be found at the apex of the right scapula. This pain is not increased by pressure; it is a case of myalgia and not of neuralgia. A great number of patients complain of this pain; it results from nervous strain or nervous irritation, provoked by an organic lesion. *Neurasthenia* and *dyspepsia* are the two great causes of the backache. Germain Sée added *anæmia* to these causes, but *anæmia* and *neurasthenia* have frequently *dyspepsia* for a common origin. The fatigue of nursing frequently provokes backache. In such cases nursing should be interrupted and preparations of iron given. The public often attributes this pain to the presence of phthisis, and the idea is sometimes correct, for consumption frequently follows phosphaturia and general *anæmia*. Backache announces the nervous strain of the individual. In other cases, the pain spreads out over the sides, indicating dry pleurisy or tuberculous toxæmia. Auscultation of the apex of both lungs should be carefully made, and arsenic combined with general tonics ordered.

In *hysteria*, backache is very frequent; it occupies the vertebral column and, limited to three or four vertebræ, the pain suggests the beginning of Pott's disease.

All of those cases should be treated on their merits, but where the cause is really *neurasthenia*, with insomnia, sensation of lassitude, &c., subcutaneous injections of lecithin, spermin, or glyco-phosphate of soda over the painful spot modifies the local pain and at the same time tones up the general condition. They succeed better than local applications. If these latter be used the following might be prescribed:—

Menthol, ʒss;  
 Guaiacol, ʒj;  
 Gomenol, ʒj;  
 Vaseline, ʒj;

or

Chloroform, ʒij;  
 Camphorated oil, ʒiiss;  
 Ext. of belladonna; grs. xv;  
 Ext. of hyosciamus, grs. xv;  
 Ext. of opium, grs. xv.

The actual cautery, a small blister or a slight galvanic current will succeed if ordinary treatment fails.

The pain in the lumbar region is frequently caused by rheumatism. Sudations and local injections of salicylate of soda (salicylate of soda, ʒj, water ʒv) form an excellent treatment in such cases. Where the lumbar pain is caused by an effort or brusque movement, it is a case of traumatic lumbago, and is readily amenable to a few applications of the thermo-cautery, followed by a galvanic or faradic current.

In diabetes, lumbar pain has been frequently noticed, due, according to Willis, to irritation of the nerves. Inflammation of two or more of the vertebræ has been mistaken for an ordinary lumbago. Every pain provoked by the movement of the vertebral column should be closely examined. Many cases of Pott's disease have been overlooked, the patient being believed to suffer from lumbago.

Another affection which gives rise to lumbar pain is cancer of the stomach, and frequently the patient will complain of nothing else, the gastric troubles being but vague at that early period of the disease. The pain, however, should not be confounded with that of neurasthenia. The latter is more dull, less paroxysmal, and disappears during sleep, whereas the pain of cancer comes in stabs, awakens the patient in the night, making him cry out. The only treatment in this case is by injections of morphia. In certain acute affections (small-pox, nephritis), pain in the lumbar region is complained of. Called to a man suffering from pain in the lumbar region as the result of cold, and whose eyelids are puffy, the urine should be examined for albumin.

 BERLIN, July 10th, 1904.

At the Surgical Congress Hr. Kuffner, Tubingen, discussed

#### THE GLYCOGEN REACTION OF THE LEUCOCYTES AND ITS SIGNIFICANCE IN SURGERY.

He said that it was known that Ehrlich had shown the presence of an iodophile substance in the leucocytes. This substance was said to be increased in some diseases, and its appearance was said to be proof of suppuration. The speaker had examined a series of 470 cases as to whether the glycogen reaction was really such a proof, and from his examination he must say it was not. It was always present in acute inflammations, whether there was suppuration or not; it was thus present in every case of appendicitis. The reaction was useless also in superficial suppuration. A negative finding was also without significance, as it could not be found in some cases of abscess. He found it comparatively frequently in tuberculosis—*vis.*, in 72 cases. Here it perhaps might serve as a proof of mixed infection, but even here it was occasionally absent. The reaction was of more value from a prognostic point of view, in so far as a diminution of the reaction after operation corresponded to cessation of the inflammatory process. The reaction could not, therefore, be recognised as a clinically important sign.

Hr. Rehn, Frankfort, spoke on

TUMOURS OF THE BLADDER IN COLOUR WORKERS. He said that he had already (in 1895) reported on cases of bladder tumour in aniline factories. He now reported on twenty-three cases. Such cases, in the speaker's opinion, would still further increase the longer such factories were in being, and the longer workpeople were employed in them. These bladder tumours were only observed in factories where aniline and its homologous and allied substances were prepared. As regarded the frequency of the disease he had instituted a collective investigation which had been extended to England. As regarded the length of time people had worked in such factories before the disease appeared, the shortest period was nine years and the longest twenty-two years. Five of the patients had papillomata, two of them afterwards becoming malignant; of the remaining eighteen, one suffered from sarcoma and seventeen from carcinoma. In four cases the carcinoma was multiple. The prognosis was unfavourable. Eleven of the cases had died.

Hr. Strauss had recently seen such a case. It occurred in a man who had been employed in a benzidine factory for twelve years, and who had passed portions of carcinoma in his urine a year before operation. The cystoscope showed a large tumour with intact bladder mucous membrane. The man had retention of urine from blocking of the outlet. The operation showed that the whole mucous surface of the bladder was healthy, that the whole bladder was filled with a tumour of soft consistence, and that the pedicle of the growth was only the size of a shilling piece. Near the pedicle was a small hard tumour, which had penetrated the submucous tissue, and which proved to be a carcinoma.

Hr. Küttner found it strange that such tumours were limited to the bladder area, and that they did not occur in other parts of the tract washed by urine.

Hr. Bardenheuer, Cologne, had seen and operated on two such cases. One of the patients soon died of recurrence, the other was still in good health after three years.

Hr. Schwerin said that the managers of colour factories had set experiments on foot with a view of preventing the disease. For years animal experiments had been carried on with a view to determining the exact cause. They had not succeeded in causing such tumours to grow, probably because they took too long to originate and the animals could not be kept alive long enough for such growth to begin.

At the Free Society of Surgeons Hr. Neumann spoke on

THE DIAGNOSIS OF DISEASES OF THE PANCREAS. (a) Pancreatic cysts that had developed towards the right, so that they gave the impression of renal cysts, and especially when at operation they were attached to the lower pole of the kidney, lay retro-peritoneally behind the cæcum and ascending colon. The pancreatic ferments would be found in the contents. (b) Symptoms of ileus with rise of temperature. At a laparotomy there was occlusion by a band; on separation of the band a stool followed. After a few days vomiting returned. A cystic tumour in the upper part of the abdomen. Suturing in of the cyst lying behind the peritoneum. The day after a brown fluid escaped with a penetrating odour. The right kidney not to be felt. The cyst contents had no pancreatic reaction; but neither chemically nor microscopically was there any indication of its origin. After some time pyonephrosis of the right kidney. Later on extirpation of the kidney. The original cyst, the position of which corresponded to a cyst of the pancreas, was a

paranephritic abscess that had developed towards the middle line.

He had recently operated on three cases of acute hæmorrhagic pancreatitis. All three died after temporary improvement in a state of diabetic coma. On post-mortem was found a large infarct of the liver.

Hr. Braun said that a boy had been trodden upon by a horse over the epigastrium a fortnight before admission, and peritonitic symptoms had come on. There was bulging of the epigastrium which was connected with the liver. Laparotomy was performed. There were distinct fatty necroses, and a cavity behind the stomach filled with a tinted secretion that contained pancreatic ferments. Drainage of the cavity was performed and recovery took place.

Hr. Koite related a case in which everything agreed with a diagnosis of cyst of the pancreas. The tumour was tapped, then incised, when there was excessive bleeding. The pancreas was packed, but the patient died from hæmorrhage. After death the pancreas was found to be healthy, and also the left kidney, but on the other hand the left suprarenal capsule was absent. There was carcinomatous growth in the wall of the cyst. He had seen two pancreatic cysts developing towards the right, but both were of a malignant nature.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, July 10th, 1904.

#### THE ACTIVITY OF FLUORESCENT SUBSTANCES.

IN the Congress for Internal Medicine, Tappeiner gave a number of demonstrations to prove the activity of fluorescent substances on the amœba. The sun's rays are equally as potent when acting through rarefied air. When applied to fish or the flagellata in this manner, a few days is sufficient to kill; in frogs and the paramœcium caudatum the time is four times as long, and he concludes that the higher animals are decidedly less sensitive to the influence of photo-dynamic substances than the lower.

Again, the enzymes, such as trypsin and diastase, lose their normal activity after a few hours' exposure to ordinary daylight. The virulence of ricini, diphtheria, and tetanus toxins can be quite destroyed by the presence of a fluorescent substance. He accordingly demonstrated dogs and guinea-pigs to which he had administered fatal doses, while the control animals died within a short time after administering the toxin. For this purpose the least refracted rays are the best, as they penetrate deepest into the tissue. As might be expected, the power of absorption is another factor that must be considered. If the tissues be painted with an eosin solution, through which the light must pass to act on any of the above toxins, the result will be negative, as the photo-dynamic power of the rays is abrogated by absorption. He affirms that the efficacy of photo-dynamic material increases by the reduced intensity of the fluorescent process.

This knowledge of fluorescent substances may yet explain many of the cures effected in cutaneous diseases. Thus four applications of the rays after painting a carcinomatous growth with eosin were effectual in curing the patient. This painting with an eosin lotion is particularly efficacious in labial and nasal carcinoma. In vulval or mammary carcinoma no evidence of success is yet forthcoming. Lupus is greatly benefited by this method, while the intensity of the secondary symptoms in syphilis are greatly reduced by its application. The efficacy of quinine in malaria is also accentuated, as the light acts effectually on the virus.

Seifert agreed with Tappeiner and related cases of lupus and sycosis non-parasitaria, which he had cured after eight applications.

#### ERYTHEMA INDURATUM SCROFULOSORUM.

Ehrmann presented three cases of Bazin's erythema scrofulosorum. This disease, he said, in prefacing his remarks, was first described by Bazin about 1860, although it appears to have been common enough before this time in both Germany and Austria. The disease declares itself on the extremities and less seldom on the trunk, in the form of walnut swellings, red at first, but soon taking on a brown knotty colour with a central part that breaks down in a cheesy discharge. It occurs commonly in people with all the symptoms of tuberculous scrofula, which will persist for years, and often recede under iodide treatment. The Röntgen rays seem to make them disappear promptly, but they unhappily soon recur again.

These cases were first diagnosed as syphilitic gummata, which was subsequently modified to erythema nodosum and scrofuloderma. Localisation was against syphilis, although the colour was in its favour, but mercury had no effect on it, though iodide had after a time. Against the nodosum theory the chronicity and hardness was fatal. The colour of erythema nodosum is red, passing into a violet colour, and finally appearing as a bluish-green surface, as in erythema contusiforme. Scrofuloderma is sharply separated by the ragged softening of the centre, whose perforations are often numerous, with irregular openings, which are often covered with the same thin, ragged pellicle; and no tuberculous bacilli are to be found in the discharge.

Neisser said that he recently had a similar case that was diagnosed as syphilis at the beginning, but was detected by the presence of tuberculous nephritis.

Schrötter said he recollected a case in 1869 that came into Professor Dittel's wards with sores on the abdomen, and no proper classification could be arrived at. Shortly afterwards hoarseness set in which resulted in ulceration of the arytenoid cartilage, which confirmed the diagnosis of syphilis. Anti-syphilitic treatment soon cleared the abdomen and throat. He considers Ehrmann's case to be of a similar character.

#### SEPSIN AND DECOMPOSING SUBSTANCES IN BOWEL.

Faust drew the attention of the meeting to sepsin, which, he said, was similar in composition to the toxin found in meat and an active poison when introduced into the organism by the glands or gastro-intestinal canal. Bergmann obtained a crystalline substance a few years ago from five grammes of yeast, which he designated sepsin, having the formula  $C_5H_{14}N_2O_2$ , from which cadaverin,  $C_7H_{14}N_2$ , can be obtained. Faust thinks this sepsin is the active principle of decomposition in the animal as yeast is the active agent in the vegetable world.

#### DIAGNOSTIC ASPIRATION OF CRANIUM.

Neisser next introduced the "probe puncture" of the cranium, which he had performed 120 times with the object of discovering the real cause of cerebral disturbance. With modern appliances this diagnostic operation can be performed almost with impunity, as the dura mater need not be injured in the hands of a skilful operator. The cranium being a hard, unyielding covering conceals all morbid changes from the surgeon, but as soon as he reaches the soft covering of the encephalon any bulging reveals abscess, hæmorrhage, or any change in the state of the vessels. There are many old products, both extra- and intra-dural, that can be diagnosed in this way that would never have come to light till after the post-mortem. Meningeal cysts and tumours can be diagnosed and removed at

the same time when found necessary. By this means he has often removed 50 c.c. of fluid and preserved life. Abscesses cannot be diagnosed with certainty, and must be probed first.

He would not say this probing was perfectly safe, nor would he encourage it without sufficient reasons, although he had only two deaths in all his operations.

#### NEW HOSPITAL.

On June 21st, Hr. Hartel, the Minister of Education, laid the foundation stone of the new "K. K. Allgemeinen Krankenhaus," which the Viennese look forward to as a new epoch in the calendar. The Kaiser was unable to be present in person, but the enthusiasm lacked nothing in his absence.

## The Operating Theatres.

### NORTH-WEST LONDON HOSPITAL.

**REMOVAL OF THE TONGUE FOR EPITHELIOMA FOLLOWING CHRONIC GLOSSITIS.**—Mr. MAYO COLLIER operated on a man, *æt.* 74, this being the third time he had operated on this patient for a definite hard mass on the fore part of the tongue. Mr. Collier said this was the third operation, the first two having been twelve and twenty-four months ago respectively. This case, he thought, was of considerable interest, in so far as the tongue had been watched by him for the last ten years. The patient had always enjoyed good health, excepting having suffered from occasional slight attacks of rheumatism, associated with a gouty tendency. In the last eight years he had complained of soreness of the tongue, for the relief of which treatment had apparently failed. The area of soreness was limited to the anterior half, the upper surface, the tip, and the borders. Effervescent wines, vinegar, salt, pepper, mustard, or any pungent substance caused extreme pain. Menthol, cocaine, chromic acid, and various other remedies had been applied by Mr. Collier without the smallest benefit. Four years ago a distinct white plaque appeared on the left of the median raphe; this was followed a year afterwards by a second plaque, below and external to the first. Associated with these plaques were several areas denuded of epithelium, causing the tongue to be extremely sensitive to pressure or contact. Mr. Collier, having his suspicions as to the nature of the upper plaque, excised this area down to the muscular tissue. It was found on microscopical examination to be a typical commencing epithelioma, which had not yet invaded the muscular tissue. The general glossitis was not improved by operation, and the tongue still remained as tender and sensitive as before. Twelve months afterwards the second plaque, below and external to the first, appeared to become more marked, and seemed to extend laterally. Mr. Collier again operated and removed the second plaque by a more extensive incision. This also was found to be commencing epithelioma. After the second operation Mr. Collier lost sight of the patient until quite recently, when the man presented himself with well-marked hardening and thickening of the tip of the tongue some little distance from the sites of the two previous operations. Mr. Collier said that nothing less than an extensive operation in this case would be of any avail, but as the patient expressed his unwillingness to undergo any operation which would prevent his feeding himself or speaking, and as his age was now 74, and there was no evidence of glandular infection, Mr. Collier contented himself with removing about half the tongue by a V-shaped incision, so as to include the areas of the two previous operations. The present operation was commenced by passing a stout

ligature through the growth and the tip of the tongue, the sides of the base of the organ were brought forward and steadied by two pairs of clutch forceps held by two assistants. This steadied and held forward the root of the tongue, and allowed the easy introduction of the deep and superficial sutures and the application of any ligatures to the vessels. Mr. Collier said that the application of clutch forceps to the sides of the base of the tongue during this operation was a matter of the utmost importance; it facilitated respiration, and the admission of the anæsthetic; it controlled hæmorrhage from the linguals, and prevented blood from passing into the larynx; it rendered the application of ligatures to the linguals perfectly easy, and it allowed the putting in of sutures and the adjusting of the cut surfaces with as little trouble as would have been experienced in adjusting a wound of the skin. The incisions were made with an ordinary pair of scissors, so as to leave a lateral flap on each side which could be adjusted to form a new tip. There was practically no hæmorrhage during these incisions. The linguals were easily found and ligatured, and the flaps were brought together by deep and superficial sutures with great ease and rapidity. Mr. Collier thought that with the precaution of holding steadily the base of the tongue with clutch forceps and with the aid of good assistants, the operation for the removal of the tongue was divested of all anxiety.

**ERRATUM.**—Owing to a printer's error, a line of the MSS. was omitted in "The Operating Theatres" of June 22nd. On page 665, second column, after line 9, the following words should come: "upon the hypoglossus muscle. With regard to the." In line 10, there should be a comma after "hypoglossal nerve," not a semicolon.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, JULY 13, 1904.

### NOMENCLATURE IN PULMONARY TUBERCULOSIS.

At the present day, when sanatoria for pulmonary tuberculosis are springing up like mushroom all over the country, there is a distinct want of some general system of nomenclature if definite information is to be gained of the results of their

work, especially if comparison is to be made between different institutions. It is customary to speak of three stages in the pathology of the disease, but these stages, like the three weeks of typhoid fever, are merely arbitrary periods fixed for the sake of convenience, and everyone conversant with the manifestations of tubercle knows that the three stages often co-exist in the same lung. The same may be said of the term "cured"—it is convenient practically, but it is scientifically unjustifiable. No patient who has suffered from tuberculosis ever returned, or ever will return, to the *status quo ante*. "Arrest" is certainly more accurate, but what one man might call arrest, another might term, with equal propriety, quiescence, and so on with every phase of the disease. It is, then, we think, desirable that some uniformity should be introduced in the terminology of the clinical conditions of tuberculosis of the lungs, for while one sanatorium may be turning out 50 per cent. of cures, another of equal repute, but with a more fastidious medical officer, might not return 5. Both practitioners might be equally conscientious, but their views as to what constituted a "cure" might differ enormously, and the comparative merits of the institutions they served would be liable to be disproportionately assessed by their committees and the public. Whatever opinion may be held as to the appropriateness of sanatoria for dealing with the disease, these institutions are now on trial in Great Britain; some persons have put forward the most optimistic predictions as to their potentialities, others are filled with gloomy forebodings. At all events, for good or for evil numbers of public and private sanatoria are now established, and it will be instructive to be able to review the record of their attainments after they have dealt with a sufficiently large number of cases to enable a fair judgment to be formed. But no such review will be possible unless a uniform system of terminology is adopted for expressing the conditions of the patients on entry, on discharge, and after such a period of years has elapsed that the effect of the treatment may be manifested as to its durability. It is well within the experience of not a few medical men that the "cured" or "arrested" patient has in some instances left the sanatorium only to die a few months later of acute general tuberculosis, so that no fair view of the success of sanatorium life can be taken till the patient has resumed his daily duties for some considerable time after discharge. In pressing for some definite system of nomenclature one would suggest that some central authoritative body, say, a medical committee of the National Association for the Prevention of Consumption, should issue a scheme detailing the various terms which should correspond to certain clinical conditions, and that each sanatorium should make returns under those headings. No such scheme could be absolute or perfect, for clinical conditions do not, from their very nature, lend themselves to exact classification, but some good, broad, working terms might be suggested to which medical officers

should conform as far as possible. As a model for such a scheme the classification of the stages of pulmonary tuberculosis issued last April by the American Climatological Association might be adopted, for although objection may be taken to some of their definitions as being arbitrary, at least they submit terms in which the general results of treatment can be commonly expressed. This Committee take as their basis of nomenclature eight phases in the history of the disease, the incipient, the first, second, and third stages, the progressive, the quiescent, the arrested, and the apparently cured, and to each of these they attach a definite meaning, expressed as to symptoms and physical signs. Thus, the incipient includes those cases in which there are "slight physical and subjective signs, with history indicative of pulmonary tuberculosis. Sputa, if present, without bacilli"; the arrested, "absence of all constitutional symptoms; expectoration and bacilli still present; physical signs may or may not persist; foregoing to have existed for at least three months"; the apparently cured, "all constitutional symptoms and expectoration, with bacilli, absent for a period of two years under the ordinary conditions of life," and so on. These definitions may not be ideal ones, but they are comprehensive and easily understood, and it would be a great advantage if they, or some such terms, could be generally adopted over here. Without some such system it will be impossible to form an intelligent opinion of the results of sanatorium-treatment as a whole, and equally impossible to decide on which side the advantage to the patient inclines with regard to the different types of sanatoria advocated by different authorities.

#### SUICIDE.

THE recent discussion at the Medico-Legal Society on the question of suicide brings this interesting subject forward again in all seriousness and with all its puzzles. The word "suicide," as Mr. Henslowe Wellington pointed out, means self-murder, and not simply self-killing, so that the stereotyped finding of the coroner's jury, "Suicide whilst temporarily insane," is paradoxical, though one cannot doubt that the verdict is generally put forward in consideration of the feelings of the distressed relatives, and not necessarily as the result of conviction. For, whatever the alienist may say, there is always a large margin of cases of self-destruction in every country for which it is difficult, indeed impossible, to account for on the ordinary ground of insanity. No one doubts that insanity, temporary and permanent, is the usual cause that incites people to self-destruction, and that premeditation and planning in connection with the act are quite reconcilable with mental aberration. The classic case of the Naples shoemaker is quite sufficient to establish the latter point. This individual first showed his claim to insanity by castrating himself and flinging the genitalia out of the window. After a year's treatment he recovered, and then he

conceived the idea that God had commanded him to suffer on the cross. For two years he worked silently making arrangements to fulfil this behest, and when he had completed his plans he was discovered one morning, nailed to a cross with a stab in his left side, hanging out of his window. The whole business was so cleverly contrived that he had managed, after completing the crucifixion, to shift the cross out of the window by movements of his body. Although rescued, he persisted in refusing food till he died. But though deliberation in preparation and determination in execution are quite compatible with insanity, there remains a number of cases in which the murder of the "self" is as true a murder as the murder of another, and it is just this group of cases that are the bane of every civilised state. Suicide among savages is said to be very rare, but in every country of which we have historical record it has been more or less rife, and in tables of figures for 1882 we find that suicides in Europe vary from 21 per million per annum in Ireland to 371 per million in Saxony. Admitting that a large number of these cases are due to mono-idealism, resulting from strain and stress, there are still many in which the evidence of rationalism is so well marked that it cannot be reasonably gainsaid. We might take the case of Whitaker Wright, for example. This man had been living for years in the lap of luxury, held in esteem and confidence by many of the highest and most trusted in the realm, and in perfect domestic felicity. When brought to the bar of justice he conducted himself with dignity, and fought his case with eminent sanity, but he had obviously decided that—to him—an adverse verdict with all that it entailed would rob him of all that life held dear, and he made his preparations accordingly. After sentence was passed, he quietly and composedly carried out his fell purpose. It is as impossible to attribute a self-murder of this kind to insanity as it is those of the Japanese officers who prefer suicide to falling into the enemy's hands, or those of the Carthaginian generals whose etiquette it was to destroy themselves if beaten in battle. We get to this position, that strong-minded men deliberately prefer death to certain alternatives, and they do so while in full possession of their faculties. They are no more insane than the man who volunteers to lead a forlorn hope to certain death—they prefer death to what they consider disgrace. In certain States self-destruction has not only been considered justifiable, but even honourable; in the island Ceos, the inhabitants were expected to poison themselves at the age of sixty to make way for younger people, and when Marseilles was a Greek colony, poison was provided by the Senate for those whose motives for killing themselves met with the magistrates' approval. In modern countries the practice of suicide, not merely as a manifestation of insanity, is certainly increasing, and although in Great Britain and America it has not reached the proportions that it has assumed on the Continent, it constitutes a

sufficiently serious problem. The epidemic, of imitative, tendency of suicide, especially of a plausible suicide, is well recognised, and it is a practice that gets more and more apologists as time goes on. It is not a problem that is easily solved, how best to check this morbid tendency. Laws have been passed in many countries to punish the would-be suicide, and to dishonour him and his family, but though drastic measures of this kind are said to have been successful in Egypt and Miletus in the past, they have certainly proved ineffectual in England. One exciting cause in modern countries that is within control is the liberty accorded to the Press to report with lurid detail and in large type the details of sensational suicides, but the question passes out of the realm of medicine when it deals with other than the self-destruction of the insane. Our duty ends when we have shown that there are rational suicides as well as insane ones, and that the verdict of "temporary insanity" is often unscientific, and, therefore, not to be commended, even on grounds of the broadest humanity.

#### THE IODISED PACK IN THE TREATMENT OF PUERPERAL SEPTICÆMIA.

IN spite of numerous and often drastic methods of treatment, puerperal infection remains a grave complication of childbed. Although in hospital wards the mortality has been reduced to about 1.5 per thousand, in private practice the death-rate is not perceptibly less than before the introduction of antiseptics, no doubt simply because advantage is not taken, and in many instances cannot possibly be taken, of their action. Injection of antistreptococcic serum, though occasionally effectual, has proved untrustworthy and is at best no more than a useful adjuvant. Curettage of the uterus, though a rational procedure, is attended by risks so considerable that eminent authorities have expressed their disapproval of its use. It is obvious, indeed, that while digital removal of placental *débris* fulfils an urgent indication, neither it nor curettage can do much in the direction of arresting the invasion of the uterine sinuses and crypts by the microbial host which has gained a footing. Antiseptic irrigations are, no doubt, useful as far as they go, but their influence is extremely ephemeral, and during the intervals the infective process runs its course unhindered. It is evident that if we wish to exert a definite effect on the septic process we can only do so by maintaining the germicide in contact with the infected walls of the uterine cavity. This is not altogether a novel suggestion, but so far as we are aware it is one which has not hitherto been systematically practised, yet the cases which we publish elsewhere, (a) reported by Dr. Cabanes, of the Medical School of Algiers, seem to show that it is possible to secure extremely satisfactory results by a procedure based on this principle. Briefly described, his method comprises the cleansing of the uterine cavity, and packing it loosely with gauze steeped in a 4 per cent. solution of iodine and

(a) See "Clinical Records."

iodide of potassium in sterilised water. The dressing is renewed every twelve hours or so until apyrexia is obtained. We gather that the treatment has been adopted in a fairly large number of cases with uniformly good results, although in several instances the virulence of the infection was conclusively demonstrated by the death of several patients infected by the same midwife, but who had not been subjected to the treatment in question. The experience of Dr. Cabanes shows first of all that the treatment is free from any risk of its own, and the promptness with which the symptoms of puerperal endometritis yielded to the dressing is equally conclusive. The method is quite within the scope of the average obstetrician; it necessitates no special appliances, and the extra trouble which it entails cannot weigh with us in view of the extreme gravity of the complication. The method is applicable even when the infective process has extended beyond the limits of the uterus proper, for although it may not directly modify the subsequent course of peri-uterine inflammation, the removal of the original and principal focus of infection cannot but exert a favourable influence on the constitutional condition which, after all, constitutes the gravest part of the problem. We see no reason to suppose that the method would prove less serviceable in other hands than it appears to have done in those of Dr. Cabanes, and its simplicity is a further reason for giving it a trial.

### Notes on Current Topics.

#### Teacher and Student.

AMONG the many topics touched on in Dr. Musser's thoughtful and eloquent Presidential Address to the American Medical Association, there is none demanding graver attention from the teachers in our hospitals and medical colleges than the question of the attitude they should adopt towards unfit students. Every conscientious teacher must, from time to time, be brought into contact with students who, by their character, whether the fault be mental or moral, must be regarded as unfit to become members of the medical profession. It may be that there is an almost entire lack of power of concentration and of memory, accompanied by stupidity, of such a degree as to render the acquisition of the necessary knowledge an impossibility. On the other hand, there may be such moral obliquity, and absence of honesty and frankness, as at any rate make professors hesitate to allow the *imprimatur* of their school to be attached for life to a man of such character. In both cases there is great difficulty in deciding on the course to adopt. It is true that in the former case the qualifying examinations will, of themselves, weed out unsuitable candidates, but it would, in many instances, be kinder and more just to warn the man of his ineligibility in his early years of study than to allow him to waste his best years in fruitless toil, presenting himself again and again for a test he can never satisfy. There are few men more to be pitied

than the "chronic medical students" who at four or five and twenty discover that the attainment of their goal is an impossibility. They have wasted five or six years in work dull and useless to them, and this waste might have been saved by friendly but firm advice at the outset. With regard to students whose moral character renders them unsuitable, the case is less hard, though to them, too, it would be bare justice to announce in the earlier years of their studentship the decision of the authorities of their school. We recognise with Dr. Musser the impossibility, in matters of individual character, of suggesting anything in the way of a general line of action, but we think he does well in emphasising the enormous responsibility in making or marring men's lives which lies with every teacher of medicine.

#### A Remedy for Physical Deterioration.

A SPIRITED effort is being made by Dr. Henri Cazalis to lift the question of physical deterioration into a stage of practical activity, so far as France is concerned. He believes that the evil is largely due to the prevailing ignorance as to the baneful effects of alcoholism, of syphilis, and of tuberculosis. His plan of campaign, which was set forth in a recent communication to the Académie de Médecine, is worthy of careful consideration in this country, where the same causes are at work, and are at the present time claiming increasing attention. Dr. Cazalis proposes that the machinery of the State be made available for the dissemination of the knowledge which is so much wanted. He points out that since the immense majority of the male population are called upon to serve in the army or in the navy, there exists a ready channel for the education of the masses, and that so good an opportunity should not be wasted. He suggests that a short set of statements might be drawn up by the Académie with a view to their being appended to the soldier's or to the sailor's "livret." In this manner a definite impression would soon be made upon the entire community. Another important measure is suggested by the appalling lack of appreciation on the part of those who contemplate matrimony of the responsibilities which they incur in relation to the health of their future offspring. Cazalis does not on this occasion press his well-known advocacy of a preliminary and voluntary exchange of certificates of health; but he considers that the State might so far intervene for the prevention of any further deterioration of the race as to provide the recipients of marriage certificates with some appropriately worded reminder of those principles which most closely affect the health and vitality of the future generation. A third suggestion, which is intended for the benefit of mothers and nurses, is so much to the point, whilst entirely free from any possible objection, that it has already been adopted in principle by the Municipal Council of Paris, and is likely to be soon adopted throughout the land. It is recommended that a set of instructions as to the management and

feeding of infants be drawn up by the Académie and supplied to parents or to their representatives when making, at the Mairie, the official declaration of a birth. Dr. Cazalis is to be congratulated upon this instalment of success in his philanthropic and most praiseworthy endeavour. The best results may be expected from some such self-working system of education in matters of health, and it cannot be doubted that the soundness and strength of the race will benefit in a full measure from this organised diffusion of elementary knowledge of family hygiene.

#### Public Vaccinators' Fees.

THE Departmental Committee that has been inquiring into the subject of the fees paid to public vaccinators and the other expenses entailed on the guardians by vaccination generally has made its report, which is now being considered by Mr. Walter Long and his advisers. What the report contains is not, of course, known, but according to Mr. Long's own statement at the time of its appointment, the Committee owed its *raison d'être* to a desire to cut down expenses. A vigorous protest was entered in these columns at the time against any attempt being made to reduce the fees now paid to the public vaccinators, and it is to be hoped that it is not too late to re-emphasise the point before the Local Government Board decision is made. The 1890 Act entailed fresh and very onerous duties on the public vaccinators, duties which were placed on them entirely in the interests of the parents of children, and not at all in their own. It was, then, only fair that their fees should be raised, for a medical man's time is his money, and the amount of time spent in going from house to house is obviously tenfold more than that spent in vaccinating children brought to a vaccination station. The Act has certainly disposed of the last reasonable objection on the part of the poor to have their children vaccinated, and it has certainly resulted in a large increase in primary vaccinations. It would, therefore, be in the nature of a breach of confidence to revert to the old scale of fees, or anything like it, and any such proposal would lead to a very justifiable outburst of indignation in the profession. The small-pox scares that have agitated the community during the few years since the passing of the Act have naturally led to a large number of re-vaccinations, and the expenses in the administration of the Act have risen proportionately. But these expenses must be considered as abnormal, and the money thus spent is surely far better utilised than in building temporary hospitals for small-pox patients and paying for their nursing and maintenance. Any attempt to go back on the contract under which public vaccinators were appointed would be viewed with unanimous displeasure by the profession.

#### The Thought of Death.

A LAY contemporary has been collecting opinions from various sources with a view to ascertaining what death means to the dying man or woman.

It is a solemn subject, and one that easily lends itself to morbid treatment and speculation, but at the same time it is one that may not unprofitably engage the thoughts of serious people. To those whose painful duty it has been to stand by the bedside of many a dying patient, as has fallen to the lot of most medical men in active practice, the actualities of the situation appear in a different light from that presented to the popular mind. There are, of course, many modes of death, which differ from each other in the widest possible manner. One man may be cut off from the enjoyment of (apparently) complete health and strength by an attack of syncope or cerebral hæmorrhage in a few seconds, whilst another dies by inches from malignant disease or tuberculosis. It is often said that death by drowning is a pleasant experience, and some persons who have been rescued after prolonged immersion have narrated happy dreams that have passed through their mind, until rudely awakened therefrom by their rescuer. This, however, is not the common lot of the nearly-drowned, and in any case the preliminary stages of asphyxia—whether by filling the air-passages with water or by any other means—are, though fortunately short, attended by most horrible sensations. The actual passage from life to death in the vast majority of cases, if not actually all, is not only painless, but occurs during a period of unconsciousness. The transition causes as little disturbance subjectively as the passage from wakefulness to sleep, and the only people who suffer in anticipation are those whose illness is accompanied by clouding of the intellectual faculties. Nor do these always suffer, for we have it on record that the celebrated William Hunter said to his friend Combe, shortly before his death, "If I had strength enough to hold a pen, I would write how easy and pleasant a thing it is to die."

#### Chalfont Epileptic Colony.

It was a bold and humane step that the founders of the Chalfont Epileptic Colony took when they inaugurated an establishment where useful employment, combined with skilled supervision, could be exercised over the unfortunate individuals whose liability to fits rendered their existence both dangerous to themselves and useless to others. The recent meeting of the governors calls attention to the fact that its aims are not only being fulfilled, but that more is being learned by experience of the capacity of epileptics and of their suitability for various tasks. The men are employed in a number of trades, such as carpentering and painting, beside farm-labouring, and the women are kept occupied with laundry, needle and housework. It can scarcely be hoped that the colony will ever be quite self-supporting, when all the circumstances under which it carries on its work are considered. Thus Dr. Aldren Turner reports that 29 per cent. of the epileptics suffer so much from mental impairment that their capacity for work even under direction is very small, whilst of the remaining 70 per cent, 57

suffer from more or less intellectual defect. This leaves, therefore, only 13 per cent. who are really averagely intelligent and capable. The work done at Chalfont has had good effects in several directions, notably in stimulating the London County Council to establish a similar colony at Horton, and it is to be hoped that now that it is evident that the epileptic can be made a useful member of society, more of these institutions will be built and equipped in different parts of the country. One of the best tests of the degree of civilisation that a State has reached is the way in which it treats its halt and maimed, and no more enlightened, humane and beneficent work could be conceived than that of making the epileptic a happy and useful member of the society in which he lives.

#### The Foundation-Stone of New St. Bartholomew's Hospital.

ON the 5th inst. the King and Queen visited St. Bartholomew's Hospital for the purpose of laying the foundation-stone of the reconstructed Hospital. On arrival Their Majesties were received by the Prince of Wales in his capacity of President of the Hospital, accompanied by the Princess, together with a reception committee of the Chairman, Sir Trevor Lawrence, the Senior Almoner, Mr. Alderman Alliston, Sir Ernest Flower, M.P., Dr. Gee, Senior Physician, and Mr. John Langton, Senior Surgeon. Prayers were read by the Bishop of London, and an address from the Governors was read by the Prince of Wales. The King then duly laid the foundation-stone, an immense block of polished red granite. An interesting little ceremony followed in the shape of the conferring of a Governorship of the Hospital upon the Queen. This is the first occasion upon which that qualification has been bestowed upon a lady. The total estimated cost of the scheme is about half a million. The City was *en fête*, and the scene at St. Bartholomew's was of a most brilliant description, worthy of the records of the ancient City with which the Institution has been for so many centuries connected.

#### The Bacteriology of Pneumonia.

FOR many years there has been waged a contest as to the causation of acute pneumonia, between those who regarded Fränkel's diplococcus as the sole bacterial cause, and those who gave a similar pre-eminence to Friedländer's pneumo-bacillus. In general, opinion seemed to have settled in favour of the diplococcus, though from time to time a case was reported where it was apparently absent, and no sufficient pathogenic germ could be found except the pneumo-bacillus. Kokawa, however, has recently pointed out that there are in reality two types of the disease, differing markedly in pathology, one being due to each of the two organisms mentioned. As points of difference, he draws attention to the greater production of mucus in the bacillary than in the coccal infection, and to the fact that in the former there is usually more of the lung involved. In

it, too, hæmorrhage into the alveoli is usually less-marked, and, consequently, during the stage of grey hepatisation there is less fibrinous coagulum. The bacilli are found embedded both in the leucocytes and in the epithelial cells, which usually show vacuoles. It is well known that the diplococcus may cause very varied infections, and so, too, in the case of the pneumo-bacillus, Kokawa brings evidence to show that it may be the causal agent in pleuritis, pericarditis, endocarditis, otitis media, and other inflammations.

#### The Health of Dublin.

IT is refreshing to find that the death-rate in Dublin has at length reached a reasonable figure. In the week ending July 2nd it was only at the annual rate of 16.7 per 1,000, being a little lower than that of London, while the mean rate during the corresponding week of the past ten years was 21.9. We have no reason to suppose that the drop in the death-rate is more than a temporary accident, depending to great extent on the weather. A large proportion of the deaths in Dublin are due to diseases of the respiratory system, and during the mild weather recently enjoyed these are naturally lessened in incidence. The real *crux* of the health question in Dublin is, of course, the housing problem, and to grapple with this no serious attempt has yet been made. It is true that the Corporation and several voluntary bodies, such as the Association for the Housing of the Very Poor and the Alexandra College Guild, are engaged in supplanting condemned tenements by suitable sanitary dwellings. Their efforts are, however, on such a small scale that they can only be regarded as instructive and successful experiments, for at the present rate of progress it would take a little over a century to substitute a sufficient number of artisans' dwellings for slum tenements to supply the working population of Dublin.

#### The Recent Hæmatogen Trial.

THE facts of the recent Hæmatogen trial at King's Bench will be fresh in the minds of many of our readers. The defendant Bauer, of Gebrüder, Bauer and Company, has drawn attention to our comments on that action contained in our issue of June 22nd, 1904. The paragraph in question mentions briefly the grounds of action and issue of the trial. It then dwells upon the hardship entailed upon the plaintiff by the adverse verdict, which deprived him of his trade mark. The only passage that can conceivably be construed as reflecting upon the defendant Bauer is the following:—"The injustice arises out of the English system which allows any trade mark to be registered, but grants it no subsequent authority or support. If Hommel's mark is bad now, it was bad at the time of registration. Why should an honourable firm be permitted to spend large sums of money in introducing a legitimate article, recognised by the medical profession, only to find out in the course of a costly trial in the High Courts that their trade mark may be used by

any unscrupulous competitor?" These sentences were obviously intended to be general in their application, and we can assure Mr. Bauer there was no intention to include him amongst the class indicated by the words "any unscrupulous competitor." If our words are capable of that interpretation we regret the circumstance extremely and willingly withdraw the passage *in toto*. It would be contrary to the policy and principles of THE MEDICAL PRESS AND CIRCULAR to exceed in any way the limits of absolutely fair comment. The English system of permitting the registration of trade marks without attempting to test their validity seems to us to invite strong editorial comment. We regret if any passing ambiguity of expression should have given rise to misunderstanding by suggesting a particular application of what was advanced as a general proposition.

#### A Slander Case.

AN action for damages for slander which promises to be interesting to medical men is listed for hearing in the Irish Courts. Dr. FitzGibbon, a medical man residing in county Wicklow, is the plaintiff, and the alleged slander arose in a rather curious way. The plaintiff's dog had a fight with another dog, and came off victorious, inflicting wounds on the other's ear. These wounds were stitched and treated by the plaintiff, and the dog ultimately completely recovered. The defendant, however, a gentleman residing in the neighbourhood, is stated to have made remarks reflecting on the plaintiff's treatment of the dog, and in general of his skill as a surgeon. The damages claimed are small in amount, but it is the first case we remember where a medical man's professional treatment of an animal has given rise to an action at law.

#### The Diminishing Birth-rate.

THE fact that the birth-rate of the United Kingdom has been steadily falling for the last thirty or forty years must sooner or later be faced by the nation. Whatever the exact meaning of the handwriting upon the wall, it deserves careful and skilled investigation by our best scientific brains. Some months ago the subject was brought forward by Dr. Taylor, of Birmingham, who attributed the decline in the birth-rate to the use of preventive methods by married persons. Such practices he claimed to be productive of a host of physical and moral evils both to the individual and the community. His views were at once accepted by many Churchmen, more especially the Bishop of Ripon, and have excited world-wide interest and discussion. Dr. Taylor's views, however, are not to pass unchallenged by the medical profession. In the present number of THE MEDICAL PRESS AND CIRCULAR (July 13th, 1904), we print an article by Dr. David Walsh upon the subject. He agrees with Dr. Taylor's main proposition that the birth-rate has fallen 5·6 during the past half century. After that point, however, he claims that hardly a single statement of that writer will stand serious examination. To begin

with, Dr. Taylor has overlooked the fact that the total birth-rate includes illegitimate births, but he nevertheless took that total rate as the basis of his bald assertion that the birth loss of the United Kingdom is due to "causes operating on the married life of its inhabitants." Dr. Walsh advocates neither side, but simply weighs the arguments advanced. His closely reasoned article should be read by all interested in the subject. It is comforting to find that medical men do not all agree with Dr. Taylor in his doleful jeremiad on the wholesale lunacy and depopulation of the United Kingdom somewhere in the near future.

#### Fried Fish and Typhoid Fever.

OF late the sensational scare attributing typhoid fever to the eating of fried fish has once more gone the round of the lay press. When the suggestion was first mooted we expressed the most frank doubt as to the truth of any such connection. The fried fish theory originated some years ago in the attempt to run to earth a mysterious epidemic of typhoid fever in South London. At the time it was carefully investigated and reported upon by Dr. Waldo, the then Medical Officer of Health for Southwark. He came to the conclusion that the outbreak could not be connected with the fish shops, and, as a matter of fact, the agency at work in the spread of that particular epidemic remains a mystery to this day. As regards fried fish, it is, on the face of it, extremely unlikely that the typhoid germs could survive the process of cooking. It is suggested by Dr. Hamer, who first raised the alarm, that the typhoid bacilli left in the intestines of the fish are so protected that they remain alive and subsequently infect consumers. It would be hard to find fish cooked whole in that manner in any fried-fish shop in London. The trade is confined almost, if not quite, entirely to slices or fillets of large fish. Without absolute or overwhelming scientific proof it seems a thousand pities that the good reputation of so cheap and valuable a popular article of food should be endangered. Further, we venture to say that convincing evidence of the theory of the spread of typhoid fever by fried fish shops has not hitherto been forthcoming. The typhoid bacillus fortunately is not a salamander that can withstand a ten minutes bath of boiling oil.

#### Early Rising.

A CERTAIN old saw, inculcated by nurses and copy-books, used to make early rising an indisputable preliminary to health, wealth, and wisdom, and the medical profession, doubtless through stupidity and prejudice, have so far clung to this tradition that their patients have ceased to look to them for sympathy when they are indolent in their habits. However, times change, and doctors with them, and just as a straw shows which way the current is flowing, so do two pronouncements emanating from medical men—one in the North of England and another in America—indicate that the tide of opinion is changing. The English physician thinks that it is dangerous to health.

and even to life to get up in a hurry, whilst the American, an alienist, by the way, thinks that this way madness lies. "The free and lazy savage gets up when he feels ready, and rarely or never becomes insane." To be forced to get up early "grinds the soul, curdles the blood, swells the spleen, destroys all good intentions, and disturbs all day the mental activities, just as a tornado disturbs and levels with advancing ruin a forest of mighty pines." The pathology of this tornadoing American may not be very exact, but his poetry is inestimable, and it behoves one in the future to take care that the arrival of one's shaving-water in the morning is allowed to pass unnoticed, lest coagulation of the blood and congestion of the spleen bring one to a bad end. The virtuous wife who rose before dawn to give a potion to her maidens may now be bidden to lie a-bed until she feels inclined to get up, or a very limited number of rubies will outweigh her market value, and the "smart set" will be able to turn night into day without a quail of conscience or a tinge of remorse. When such "medical experts" are quoted in the daily papers, one can only animadvert on the wonderful progress of medicine since our fathers' time.

#### The Cause of Appendicitis.

WITH appendicitis on every side, and people keenly interested in the subject, it is natural that they should constantly be asking their doctor, "What is the cause of appendicitis?" The medical attendant, for his part, may either enter into a technical disquisition which may leave the inquirer about as wise as when he began, or he may take refuge in the prevailing ignorance of the profession, and answer, "Nobody knows." At any rate, the position is not an enviable one, and does not enhance his prestige. A paper by Dr. Rubin, of Chicago, in the *Medical News*, details some ingenious experiments made by himself with a view to discovering some mechanical explanation for the condition. The method he adopted was to cut out a portion of the gut, which included the cæcum and the appendix, from the cadaver, of a subject who had died of some affection not connected with the intestine. After washing the excised bowel, he placed in its lumen various objects, such as beans, peas, and shot, and then shook and rolled the intestine about in imitation of peristaltic movement. Although he used considerable force, none of the objects entered the cavity of the appendix. He then proceeded to blow out the bowel with gas, keeping the peas and beans still in the lumen, and when the inflation was complete, he proceeded to carry out the same shaking and rolling process. In nine out of ten experiments he found that the appendix became filled with shot, whilst in two even peas entered the cavity. The only case in which the shot did not enter freely was one in which the appendix was hypertrophied and had a stricture of the lumen, and even in this instance one small shot found its way in. It would seem, therefore,

that flatulence would be very likely to be a predisposing cause of appendicitis, and that the blowing up the cavity of the appendix with intestinal gas would enable portions of fæces and foreign bodies to gain access to it. If this be indeed the case, it may prove possible to avert threatened attacks of appendicitis by diet and drugs, but till something more definite is known, one must be content to follow the old course.

#### The Diagnosis of Beri-beri.

IN view of the recent outbreak of beri-beri which has occurred among the Chinese labourers imported into South Africa, a correspondent has written to the *Times* enclosing an extract from the address delivered by Sir Patrick Manson at St. George's Hospital on October 1st, 1897, in which the need for post-graduate instruction in tropical medicine was eloquently brought forward. Two years later the London School of Tropical Medicine was founded, mainly through the instrumentality of the Right Hon. Joseph Chamberlain, and in connection with the Seamen's Hospital Society; this institution has played a most important part in the education of medical men in tropical diseases. This fact would seem to have been forgotten by the writer of the letter, for he points out that beri-beri is common in the port of London, and implies that a correct diagnosis is seldom made. Were there no opportunities for seeing the disease and of receiving instruction as to its clinical and pathological features such an implication would be justified, but now that there are two schools of tropical medicine in this country there is no particular reason why all medical practitioners should not have a nodding acquaintance with the malady. Difficulty of recognition is most apt to occur when the disease appears in a sporadic fashion, for then it is only the more prominent symptoms which are especially noted, such as heart disease, dropsy, or peripheral neuritis. The presence of the last-mentioned symptom, when due to maladies other than beri-beri, is liable to be confounded with that affection. The three forms of the disease recognised by Cantlie, the wet, dry, and mixed, are not always separated one from the other, but the mixed variety is that most usually encountered. The presence of œdema limited to the front of the shins, the absence of knee-jerks, the existence of a patch of anæsthesia on the inner side of the calves, combined with some evidence of heart weakness, would lead one to suspect beri-beri in any given patient.

#### PERSONAL.

THE QUEEN has presented a signed engraving of herself to the Royal University of Ireland, through the Chancellor of the University, the Earl of Meath. Her Majesty is an Honorary Graduate of the Royal University.

HIS MAJESTY THE KING, accompanied by the Queen, on the 5th inst. proceeded in semi-state to St.

Bartholomew's Hospital, when he laid the foundation stone of the new additions to the present structure.

MR. E. B. P'ANSON, the architect of the new building, had the honour of a special presentation to His Majesty immediately before the laying of the foundation stone.

HIS MAJESTY THE KING presented £1,000 to the Building Fund.

HER MAJESTY THE QUEEN was presented with the first lady governorship granted by St. Bartholomew's.

W. H. CLAYTON-GREENE, B.A., M.B., B.C.Cantab., F.R.C.S.Eng., has been appointed supernumerary surgeon in charge of out-patients to St. Mary's Hospital, Paddington.

PROFESSOR JOHN SHOEMAKER, the distinguished American physician, was recently presented with a silver shield and a silver loving cup by the Medico-Chirurgical College of Philadelphia at a celebration of the thirtieth anniversary of his entrance into the medical profession. A brilliant function was held in the college, with the foundation and the development of which Dr. Shoemaker has been intimately connected.

THE Wightman Lecture of the Society for the Study of Disease in Children will be delivered at the Hotel Cecil on July 15th, at 6.30 p.m., by Mr. R. Clement Lucas.

THE Marquis of Londonderry, as President of the Board of Education, on the 11th inst. received a medical deputation in favour of the compulsory teaching of hygiene and temperance in public elementary schools.

THE Royal College of Physicians of London has announced the following lecturers for 1905:—Dr. W. C. Bosanquet as Goulstonian lecturer; Dr. W. H. Allchin as Lumleian lecturer; Dr. Norman Moore as Fitz-Patrick lecturer; Dr. Leonard E. Hill as Oliver-Sharpey lecturer; and Dr. W. H. R. Rivers as Croonian lecturer.

THE Earl of Derby, as Chancellor of the University of Liverpool, early in the present month presided at the first public conferring of degrees of that university, and was himself presented for the honorary degree of D.C.L.

DR. LOUDINI was recently entertained at a public dinner and presented with a purse of gold by the Liverpool University Association, on the occasion of his assumption of the office of Bursar of the University.

WE regret to announce that Mr. F. A. Barton, M.R.C.S., the well-known expert in airship matters, met with a serious accident last week owing to the explosion of a gas cylinder while engaged in filling his balloon. From latest accounts he is doing well.

DR. JAMES WALLACE, on the occasion of his departure from Stonehaven, has been presented with a silver tea-tray by his numerous friends and patients.

MR. WALTER C. C. PAKES, M.R.C.S., has received a handsome presentation in recognition of his services as medical officer of health to the Rand Plague Committee, a post which he has recently resigned.

MR. CLEMENT LUCAS presided at the biennial festival dinner of Guy's Hospital Medical College held on the 5th inst. at the Hôtel Métropole, London.

PROFESSOR GEORGE GAFFKY, who has left his Professorship at Giessen to succeed Professor Koch at Berlin, was one of Koch's earliest assistants, and accompanied him on the cholera expedition of 1883-84.

THE NEWLY-ELECTED PRESIDENT OF THE R.C.S.I.

MR. ARTHUR CHANCE, F.R.C.S.I., Vice-President, who succeeds Sir Lambert Ormsby, President of the Royal College of Surgeons, Ireland, has filled the posts of Surgeon-in-Ordinary to the Lord Lieutenant of Ireland and Examiner in Surgery to the College. He is Surgeon to the Mater Misericordiae and to the Dublin Orthopaedic Hospitals, and consulting surgeon to the St. Michael's Hospital. Our portrait is from a photograph by F. P. D'Arcy, Dublin.

### Special Correspondence.

[FROM OUR OWN CORRESPONDENT.]

#### SCOTLAND.

FIRE IN THE EDINBURGH ROYAL INFIRMARY.—Considerable damage was done in the Pathological Department of the Infirmary by a fire which occurred on July 4th, shortly after midday. Dr. Shennan, the pathologist, was engaged on a post-mortem examination at the time, and the alarm was given by molten lead dropping through the ceiling of the theatre, which was occupied by students. The room above, used as a pathological laboratory, was discovered to be in flames, and, notwithstanding the efforts of the Infirmary brigade and the city fire brigade, the whole upper storey of the building was gutted, damage to the extent of about £1,000 being caused, besides the loss of much valuable pathological material. The fire is believed to have been caused by an electric wire fusing, and the only reason why it assumed such serious dimensions was an inadequate water supply. This was a matter of strong complaint at the usual managers' meeting held in the afternoon, and it was decided to communicate with the Water Trust on the matter. The Pathological Department is, of course, quite isolated from the rest of the hospital, but if a fire took place in the main building the defective water supply might easily have more serious consequences than in this instance. The laboratory of the Royal College of Physicians has been placed at the disposal of the Infirmary pending the restoration of their own.

PRESENTATION TO PROFESSOR HEPBURN, CARDIFF.—The eighteenth annual dinner of the Edinburgh Company R.A.M.C. Volunteers was made the occasion of a presentation to the former commanding officer, Surgeon-Major Hepburn, who, during so many years of his work

in Edinburgh, took the deepest interest in the welfare of the corps. The presentation took the form of a gold watch, and was subscribed for by former members of the company all over the world. In a felicitous speech, Lieutenant Waterston, the commanding officer, expressed the warm feelings of regard which all the past and present members of the company felt for Professor Hepburn. Between seventy and eighty members of the company were present, among the guests being Colonel Hughes, D.S.O., R.A.M.C., the P.M.O. Scottish District, Major Scott, R.A.M.C., and Mr. C. W. Cathcart, the first commanding officer of the Edinburgh Company.

### Correspondence.

[We do not hold ourselves responsible for the opinions of our Correspondents].

#### SANITARY AND BUILDING BYE-LAWS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Your correspondent, "Modernus," must be of a particularly sanguine temperament if, with any knowledge of the Local Government Board, its bye-laws, and their administration by local authorities, he imagines the refinements of sanitation he suggests are likely ever to be adopted and put in force. Very few municipalities strictly enforce the present model bye-laws, which they almost all adopt; and where the council, urban or rural, as often happens, is composed of or dominated by mean, ignorant, and vulgar men—small tradesmen and jerry builders—they do not enforce any which seem irksome to their interests or those of their friends. Medical officers of health are here, as in so many other directions, practically powerless. They may point out quietly to the sanitary committee the iniquity of disregarding essential measures for the prevention of disease; but they are the servants of the authority, and it is as much as their place is worth to raise any public protest against even the most glaring of abuses. The great bulk of the public know little and seem to care less about local government. There exists almost complete lack of local patriotism in this regard throughout the country. Men of position and intellect as a rule refuse to take any part in local government. They will not offer themselves as candidates for membership of councils, nor take any active steps in putting fit men on. Democratic institutions cannot be administered to full advantage unless all intelligent citizens take a due interest in their working. The present apathy forms a danger to the nation. Even in London not more than 40 per cent. of the burgesses could be induced to vote at the last County Council election. There exists in England very little of the municipal corruption such as disgraces the United States; but a very great part of the legislation which, if energetically enforced, would bring the country into a position relatively of vast sanitary improvement is now either altogether neglected or only carried out in a partial and ineffective fashion.

I am, Sir, yours truly,

July 7th, 1904.

M. O. H.

#### LUNACY—A PRACTICAL DEFINITION.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Although I have not the advantage of your correspondent "R. L." in legal training, he will excuse me saying that his letter scarcely touches mine except when he refers to my having incidentally adopted the perhaps not very graceful expression of "a bullying counsel;" and I cannot, moreover, quite agree with him if he thinks the millennium has quite arrived amongst gentlemen at the bar, as it is proverbially whispered that when a counsel has no leg to stand upon he resorts to the practice of "bullying" his opponent.

Your correspondent in his letter, June 22nd, calls attention to what appears to me the indefiniteness of insanity and quotes the evidence of Dr. Distin and his vague opinion expressed in court, viz., "the man was a

criminal lunatic, but that it was one of those cases where they could not certify insanity"; and in my reply I supplemented this by reciting a case of a medical witness who informed a Counsel that it would take two days (or to that effect) to formulate a definition, so on the face of all this I ventured to suggest "a morbid condition of mind requiring supervision" as a likely definition. Your correspondent does not, I note, criticize my definition, neither does he offer one of his own; but on the other hand, strange to say, he appears now neither to acquiesce with Dr. Distin because he adds—"In such a case as the Archdeacon's brother a lawyer would, perhaps, take the view that other people can be left to take care of themselves till crime has brought the lunatic within reach of the law." Surely, "R. L." would not endorse the view of leaving, say, a homicidal or suicidal patient, or tending that way, to take care of himself till a crime was committed; if not, what relevance is there in making this remark?

Now, sir, I apprehend that the law takes cognisance of insanity in its criminal and civil code, and constitutes itself the guardian of an insane person *only in one sense*, and that is so far as the liberty or freedom of action of any individual is concerned; so that to conceive and differentiate any practical definition of insanity, we must take care as far as possible to conform to and limit such definition to the ideas which the law entertains on the subject—i.e., liberty.

In a letter in your columns a short time ago I defined insanity in its broadest, logical and most comprehensive area as "a greater or less deviation from reason"; but it is obvious that such a wide definition would embrace all minds and delusions the outcome of feeble judgment and defective reasoning powers which, although these weaknesses might render such minds unfavourable competitors in the battle of life, nevertheless would be insufficient to convince a jury of the necessity for legal supervision, neither do we wish to convince them in such cases. On the other hand we have to show, on a lunacy certificate supplied to us by law, from our own observation and from hearsay evidence, *that degree* of "morbid condition of mind requiring supervision" and to substantiate such certificate in a law court if need be. I know not what your correspondent thinks of my definition, and it is open to anyone to improve upon it or furnish a better. However, it is certain that when a medical witness proffers evidence on insanity in a court and he is asked the abstruse question, "What is insanity?" he should be armed to the teeth with some answer, however simple, which may appeal to and satisfy the commonsense and intelligence of an English jury.

I am, sir, your truly,

Brighton, July 7th, 1904.

CLEMENT H. SERS.

#### THE MIDWIVES' INSTITUTE.

WE have received from the secretary of the Midwives' Institute, and also from Messrs. Brown, Ringrose, and Lightbody, letters repeating the denial of the appearance on the agenda paper of the former body of a paper called "Malthusianism, or Tired Ovaries." The second letter contains the following paragraphs:—  
"Our clients, the Incorporated Midwives' Institute, have consulted us with regard to the statements contained in the leading article headed 'The Lifting of the Veil,' in your issue of June 8th last, and in your comment at the foot of the Institute's secretary's letter to you as in your issue of June 29th last.

"The statements contained in the leading article of which the Institute complain have been already clearly indicated in their secretary's letter to you above referred to, and in her further letter to you of June 30th last, of which we are instructed you have taken no notice. Further, the secretary's letters have already amply repudiated as untrue the statements contained in the article in question. We therefore consider it unnecessary to explain or repudiate same further.

"The further statements contained in your comment above referred to, viz., that the writer of the leading article saw an agenda paper purporting to come from the Midwives' Institute containing the title of the

paper as given in the leading article, and stating that such paper was down for the next meeting of that Institute, however, gives our clients still further cause for complaint, as it is, we are instructed, absolutely untrue that any such paper was ever put down on any agenda of the Incorporated Midwives' Institute.

"It would appear, however, from a record of the proceedings of the Midwives' Society (of Manchester?) for December 2nd, 1897, that a paper with the title referred to in the leading article was then read before that Society. Our clients cannot believe that either the writer of the leading article or you yourself could through ignorance thus confuse the name or proceedings of The Incorporated Midwives' Institute of London with those of The Midwives' Society of Manchester, the latter being, we are instructed, a small society established some years ago at Manchester (whether now existing our clients are unaware); but they very strongly object to their Institution being confused in any way with the Society referred to."

We, of course, accept this explicit disclaimer, but we would point out that a similar doubt to that which makes our correspondents add (of Manchester?) to the title of the Midwives' Society is possibly responsible for the confusion which is stated to have occurred in our case between the "Midwives' Institute" and the "Midwives' Society." The agenda paper in question was, to our knowledge, sent to a nurse, as an inducement and with an invitation to join the Midwives' Institute or Society. We were distinctly under the impression that the invitation came from the former body, but as one society would be most unlikely to enclose the agenda paper of another unless there was a very close connection between the two, we have pleasure in accepting our correspondents' repudiation. Will they in return inform us if the "Incorporated Midwives' Institute" was absorbed or is in any way connected to or affiliated with the "Midwives' Society?"—ED.

## Obituary.

### MR. JOHN BIRKETT.

WE regret to announce the death of Mr. John Birkett, at his residence, Sussex Gardens, Hyde Park, London, on the 6th inst., in his ninetieth year. He was educated at Guy's Hospital, and in Paris, and admitted a member of the Royal College of Surgeons, England, in 1837, elected an honorary Fellow in 1844, and Jacksonian prize winner for 1848. He was surgeon and lecturer on surgery at Guy's Hospital and subsequently consulting surgeon; examiner in surgery to the Royal College of Physicians, London, Hunterian Professor of Surgery and Pathology, and examiner in surgery to the University of London, and for many years Government Inspector of Anatomy in England and Wales. Mr. Birkett was also president of the Royal College of Surgeons, England, a Fellow of the Royal Medical and Chirurgical Society, and of the Medical Society of London.

## Medical News.

### Prize Day at Guy's Hospital.

THE distribution of prizes to the successful students of the Guy's Hospital Medical School took place on July 6th, at the Hospital. The prizes were presented by Lord Goschen and among the medallists and prizemen were S. J. Darke, who gained the £100 open scholarship in Arts. H. A. Sanford was awarded the £150 open scholarship in science, and C. W. Greene took the £50 scholarship for university students. Lord Goschen in his address expressed admiration at the progress made in scientific research, and pointed out that further research and study were required to open up the Hinterland of the unknown in medical science. All students, however, could not be scientific investigators, the country must have general practitioners as well. He warned his hearers that the medical student from his earliest education and work necessarily dealt with facts and the material aspects

of nature, so that he had reason to guard himself against materialistic influences. There was another danger, and that was from the moral point of view. The close and constant contact with the darker side of human nature—with sin, crime, and disease—might lead a medical man to become pessimistic, but he urged them to hold to their faith in human nature and to hold high the standard of honesty. The garden party held afterwards in the Hospital gardens was attended by over 3,000 people, and the gathering proved a brilliant success.

### The North-East London Clinical Society.

THE annual dinner of the above Society was held on Friday, July 8th, 1904, at the Great Eastern Hotel, Liverpool Street. The President, Dr. J. W. Hunt, occupied the Chair. Among those present were Dr. F. de Havilland Hall, Dr. A. T. Davies, Mr. Langton, and Mr. L. H. G. Kerr. In replying to the toast of "The Society," Dr. R. Murray Leslie, the president-elect for the ensuing session, remarked that the North-East London Clinical Society differed in many respects from other London medical societies, in that the meetings were held during the afternoons, which had been found to be the most convenient time for the great majority of busy practitioners. He also referred to the excellence of the clinical material, and to the free discussions which characterised the meetings. He hoped that members would avail themselves of the opportunities which were extended to them of attending the lectures to be delivered at the North-East London Post-Graduate College, for issuing which invitation he had the authority of the Dean, Dr. A. J. Whiting. A good musical programme was provided, and altogether the members, together with their lady friends, spent a most enjoyable evening.

### The Oxygen Hospital.

H.R.H. PRINCESS LOUISE, as patron of this institution, attended the annual meeting last week in Fitzroy Square, at which many members of the committee and other supporters were present. Mr. Burdett-Coutts occupied the chair, and urged the great need of further financial support. A sum of between £700 and £800 was, he said, needed for immediate requirements, and upon a very slender income the hospital was fulfilling a really valuable work of scientific and pathological research. A vote of thanks to Her Royal Highness was moved by Mr. J. B. Lonsdale, M.P., and seconded by Dr. Stoker, who said that he first derived the idea of using pure oxygen from the Zulus, who exposed their wounds or injuries to the fresh air and sunshine of the hills and uplands with frequent gratifying results.

### Royal College of Surgeons in Ireland.—Prize List, Summer Session, 1904.

*Barker Anatomical Prize.*—£31 10s., C. Cooper.  
*Mayne Scholarship.*—£15, A. N. Crawford.  
*Carmichael Scholarship.*—£15, J. Prendiville.  
*Gold and Silver Medals in Operative Surgery.*—Gold: J. S. Dunne. Silver: P. D. Sullivan and J. C. Murphy (equal).  
*Stoney Memorial Gold Medal in Anatomy.*—J. Prendiville.

*Practical Histology.*—H. C. Carden, first prize (£2) and medal; D. Adams, second prize (£1) and certificate.

*Practical Chemistry.*—R. H. F. Taaffe, first prize (£2) and medal; F. C. Warren, second prize (£1) and certificate.

*Public Health and Forensic Medicine.*—M. Cohen, first prize (£2) and medal; T. H. Massey, second prize (£1) and certificate.

*Materia Medica.*—F. C. Warren, first prize (£2) and medal; J. B. Kelly, second prize (£1) and certificate.

*Biology.*—J. C. S. Day, first prize (£2) and medal; T. C. Boyd and H. W. White (equal), second prize (£1) and certificate.

The winter session will commence in October. Prospectus now ready.

### Doctor's Death from Plague.

NEWS of the death of Dr. Noel Unsworth, Cairo, is to hand. He took an active part in combatting the cholera epidemic of 1902, and had subsequently been engaged on plague duty in the delta for the Sanitary Department. He contracted bubonic plague three days before, and died last Sunday morning.

## Notices to Correspondents, Short Letters, &c.

**CORRESPONDENTS** requiring a reply in this column are particularly requested to make use of a *distinctive Signature or initial*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

**ORIGINAL ARTICLES** or **LETTERS** intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

**CONTRIBUTORS** are kindly requested to send their communications, if resident in England or the Colonies, to the Editor at the London office; if resident in Ireland, to the Dublin office, in order to save time in re-forwarding from office to office. When sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

### TRIALS OF MEDICAL MEN.

The following, according to the *Captain*, are some of the sweets of a doctor's life:—If he goes to Church regularly, it is because he has nothing else to do; if he does not go, it is because he has no respect for the Sabbath or religion. If he has a good carriage, he is extravagant; if he uses a poor one, on the score of economy, he is deficient in necessary pride. If he visits his patients every day, it is to run up a bill; if he does not, it is unjustifiable negligence. If he says anything about religion, he is a hypocrite; if he does not, he is an infidel. If he uses any of the popular remedies of the day, he indulges the whims and prejudices of the people to fill his pockets; if he does not use them, it is from professional selfishness. If he is in the habit of having counsel often, it is because he knows nothing; if he objects to have it, on the ground that he understands his own business, he is afraid of exposing his ignorance to his superiors. If his horse is fat, it is because he has nothing to do; if it is lean, it is because it does not get enough to eat. If he drives fast it is to make the people think somebody is very ill; if he drives slow, he takes no interest in the welfare of his patients. Finally, if he gets paid for one half of his services, he has the reputation of being a great doctor. "M. D."

A **CARDITOR** suing a doctor in the Clerkenwell County Court mentioned that the debt was "for a pair of trousers to bury the doctor's wife in." Visibly startled, the judge exclaimed, "Surely burial reform has not come to that yet."

### AN OFT REPEATED EPIGRAM.

The following epigram was quoted by Dr. Hutchinson in a debate on the Licensing Bill in the House of Commons. It can hardly be said to be *ad rem* to the discussion, and was moreover incorrectly reported. It should run thus:—

God and the Doctor we alike adore,  
But only when in danger, not before;  
The danger past, both are alike requir'd,  
God is forgotten, and the Doctor slighted."

**EDINBURGH STUDENT**.—We have seen no announcement of a new edition of the book referred to and think another is unlikely just yet.

### THE CENTRAL MIDWIVES' BOARD.

We understand that the resolution at the last meeting reported in our issue for July 8th that "registered members of the medical profession only be eligible for appointment as examiners under the Central Midwives' Board" was not carried: Dr. Japp Sinclair, Dr. Ward Cousins, and Mr. Parker Young voting for; and Dr. Cullingworth, Miss Wilson, Miss Oldham, and Miss Paget against it.

## Meetings of the Societies, Lectures, &c.

WEDNESDAY, JULY 13th.

**DERMATOLOGICAL SOCIETY OF LONDON** (11 Chandos Street, Cavendish Square, W.).—5.15 p.m. Demonstration of Cases of Interest.

**MEDICAL GRADUATES' COLLEGE AND POLYCLINIC** (22 Chenies Street, W.C.).—4 p.m. Mr. L. Chestle: Clinicque. (Surgical.) 5.15 p.m. Dr. S. Taylor: Hemoptysis and its Treatment.

THURSDAY, JULY 14th.

**THE BRITISH GYNECOLOGICAL SOCIETY** (20 Hanover Square, W.).—Specimens, Mr. Christopher Martin: (1) Bone Crochet Hook removed from the Abdominal Cavity. (2) Two specimens showing Arrested Development of the Uterus. Dr. Macnaughton-Jones: (1) Specimen illustrating the Relation of Hydrosalpinx to Accessory Fallopian Tubes, with notes. (2) Specimens of Adnexal Tumours bearing on the question of Hysterectomy. (3) Adnexal Sections with the Epidiascope. Mr. Bowreman Jessett: (1) Removal of Large Fibro-Cystic Tumours by Abdominal Hysterectomy, followed by gangrene of the Right Leg. (2) Uterus removed by Abdominal Hysterectomy with large Sub-mucous polyp Intestinal Fibroid, and Sub-peritoneal Fibroids. Dr. Jervois Aarons: A New Uterine Mop.

**NEUROLOGICAL SOCIETY OF THE UNITED KINGDOM** (11 Chandos Street, Cavendish Square, W.).—8 p.m. Clinical Meeting. Exhibition of Cases of Myelopathic Muscular Atrophy.

**MEDICAL GRADUATES' COLLEGE AND POLYCLINIC** (22 Chenies Street, W.C.).—4 p.m. Mr. Hutchinson: Clinicque. (Surgical.) 5.15 p.m. Dr. S. Taylor: Hemoptysis and its Treatment.

**MOUNT VERNON HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST** (7 Fitzroy Square, W.).—5 p.m. Dr. F. Price: Aortic stenosis (illustrated by cases). (Post Graduate Course.)

FRIDAY, JULY 15th.

**SOCIETY FOR THE STUDY OF DISEASE IN CHILDREN** (Victoria Hall, Hotel Cecil).—6.30 p.m. Mr. R. C. Lucas: The Hereditary Bias and Early Environment in their Relation to the Disease and Defects of Children. (Wightman Lecture.)

## Vacancies.

- Borough Asylum, Canterbury**.—Assistant Medical Officer.—Salary £140 per annum, with furnished quarters, board, and laundry. Applications to the Medical Superintendent.
- Ayr District Asylum**.—Assistant Medical Officer.—Salary £120 with board, furnished apartments, attendance, and washing. Applications to the Medical Superintendent.
- City of Leeds—Infectious Diseases Hospitals**.—Second Assistant Resident Medical Officer. Salary £120 a year, with board, lodging, and washing. Applications to the Medical Superintendent, City Hospitals, Beacroft, Leeds.
- Brecon and Radnor Asylum, Talgarth, R.S.O.**—Assistant Medical Officer. Salary £140 per annum with furnished apartments, board, attendance, and laundry. Applications to the Medical Superintendent.
- The Royal National Hospital for Consumption and Diseases of the Chest, Ventnor**.—Senior Resident Medical Officer. Salary £200 per annum, with board and lodging in the Hospital. Applications to the Secretary, 34 Craven Street, Charing Cross, London.
- Royal National Hospital for Consumption and Diseases of the Chest, Ventnor**.—Two Assistant Resident Medical Officers. Salary £100 per annum, with board and lodging in the Hospital. Applications to the Secretary, 34 Craven Street, Charing Cross, London, W.C.
- Hereford County and City Asylum**.—Senior Assistant Medical Officer. Salary £150 per annum, with board, lodging, and laundry. Applications to the Medical Superintendent.
- Southwark Union, London**.—Second Assistant Medical Officer, Infirmary, East Dulwich Grove S.E. Salary £100 per annum, with board, lodging, and washing. Applications to Howard C. Jones, Clerk, Union Offices, John Street West, Blackfriars Road, S.E.
- Dorset County Hospital, Dorchester**.—House Surgeon.—Salary £100 per annum. Applications to W. E. Groves, Valetta, Icenway.

## Appointments.

- BLAIR, CHARLES, M.D., Durh.**, F.R.C.S. Eng., Surgeon to the Western Ophthalmic Hospital, London.
- CLAYTON-GREENE, W. H.**, M.B., B.C. Cantab., F.R.C.S. Eng., Supernumerary Surgeon in Charge of Out-patients to St. Mary's Hospital, Paddington.
- COURTENAY, F. W. E.**, L.R.C.P., L.R.C.S., Medical Referee to the Empire Guarantee and Insurance Corporation, Limited.
- EDMONDS, EDGAR FLETCHER, M.B.**, B.S. Durh., Assistant House Surgeon to the Rotherham Hospital and Dispensary.
- EMMERSON, A. T.**, M.D. Toronto, Clinical Assistant to the Chelsea Hospital for Women.
- JOHNSON, H. MULREA, M.B.**, B.Ch., Chief Demonstrator of Anatomy in Trinity College, Dublin.
- MACKENZIE, MARION E.**, M.B., Ch.B. Edin., House Surgeon to the East End Branch of the Children's Hospital, Sheffield.
- NICHOLLS, T. J.**, L.R.C.P., and S.I. House Surgeon to Mercer's Hospital, Dublin, *vis à* Dr. Willington resigned.
- PALMER, FREDERICK S.**, M.D., M.R.C.P., Assistant Physician to the West End Hospital for Diseases of the Nervous System.
- PATER, ALASTAIR GORDON, M.B.**, Ch.B. Aberd., Senior House Surgeon to the Great Northern Central Hospital.
- ROWLETTE, ROBERT JAMES, B.A.**, M.D. Dubl., Anaesthetist to the Incorporated Dental Hospital of Ireland.
- SASS, WILFRID, M.R.C.S.**, L.R.C.P. Lond., Assistant Anaesthetist to the Cancer Hospital, Brompton, S.W.
- STEHEEN, W.**, B.A., M.B. Toronto, Clinical Assistant to the Chelsea Hospital for Women.

## Births.

- DICKSON**.—On July 5th, at The Lodge, Wye House, Buxton, the wife of Graeme Dickson, L.R.C.P., &c., of a daughter.
- SEALE**.—On May 28th, at Oakfield, Ceres, Cape Colony, the wife of Edward A. Seale, M.D., of a daughter.

## Marriages.

- CLARKE-O'FARRELL**.—On July 6th, at St. Bartholomew's Church, Dublin, Major J. L. J. Clarke, East Yorkshire Regt., D.A.A.G., 3rd Army Corps, only son of Lt.-Colonel Alfred Clarke, M.D., Royal Military College, Camberley, to Lillian, only daughter of Sir George and Lady O'Farrell, of 19 Fitzwilliam Square.
- GODDARD-ROGERS**.—On July 7th, at the Parish Church, Watford, Claud Francis, the fourth son of the late Eugene Goddard, M.D., of Highbury, and Mrs. Goddard, of Fernbank, Sudbury, Harrow, to Annie Evelyn, the eldest daughter of James Rogers, of Watford.
- HARTLEY-PERRIN**.—On July 6th, at the Parish Church, Harrow-on-the-Hill, John Dawson Hartley, F.R.C.S., of 39 The Terrace, Gravesend, elder son of Stephen Hartley, High Street, Harrow, to Margaret Young, second daughter of William Perrin, of Harrow.
- HELSDON-PREEDY**.—On July 6th, at St. Peter's Goodworth, Clatford, Charles Victor Helsdon, M.R.C.S.E., of Penton, Mewsey, Hants, to Catherine, younger daughter of the late John Preedy.
- PATCH-SMITH**.—On July 5th at Esher Parish Church, Burnet Graham Patch, R.A.M.C., youngest son of Colonel R. Patch, C.B., Indian Army, of Fersfield Newton Abbot, to Edith, younger daughter of E. G. Warren Smith, of Esher.

## Deaths.

- BIRKETT**.—On July 6th, at 1, Sussex Gardens, Hyde Park, John Birkett, F.R.C.S., in his 90th year.
- CRAIGIE**.—At Blagdon, near Bristol, Francis Louis Craigie, the fourth son of the late Dr. Craigie, and Mrs. Jane Craigie, of Holyoake.

### THE DIMINISHING BIRTH-RATE.

By DAVID WALSH, M.D. Edin.,

Senior Physician, Western Skin Hospital, London, W., &c.

#### PART II.

*Assumption III: That a falling birth-rate necessarily indicates a failure in national prosperity.*—Dr. Taylor quotes as his keynote Ruskin's dictum "that the final outcome and consummation of all wealth is the producing as many as possible full-breathed, bright-eyed and happy-hearted human creatures." The whole trend of his article, however, shows that he is governed by the underlying fallacy that a steadily increasing birth-rate is, by sheer force of numbers alone, necessarily a sign of national prosperity. In young or undeveloped countries, that may be the case. In all countries, however, there is a limit of supportable population, and when that point is reached disaster must follow.

Following a method that is now classical, let us take the case of an imaginary island, of an area, say, of twenty square miles, which by its natural resources can maintain a population of two thousand souls. It is obvious that if the population exceed that maximum, general want and misery will result, until disease and starvation reduce the numbers to two thousand or less. But suppose that ships from other lands visit our island, and enable its inhabitants to exchange their surplus granite and other products for the foreigners' foodstuff, then a fresh lease of life will be granted them. Some of the surplus population, moreover, will be able to relieve the pressure at home by emigration. Still, twenty square miles will not support an indefinite number of people, however great their natural resources and their trading facilities. When the population reaches the second or artificially raised maximum, say, of twenty thousand, another disastrous readjustment must take place, and the inhabitants will have either to die down again or to emigrate. To introduce children into an over-crowded society of that kind would be to subject them to misery and death, to say nothing of the injury inflicted upon the already existing population. Yet, if we agree with Dr. Taylor that it is wrong to place a check upon lawful procreation, the parents of that community would be morally constrained to go on rearing children under conditions of food and air starvation. The starveling generation thus produced would be short-lived and riddled with insanity, crime, alcoholism, and other signs of degeneracy.

Let us now apply the test of the supportable limit of population to the two statements of Ruskin, which were accepted as axioms by Dr. Taylor. The propositions run thus: First, "There is no wealth but life. That country is richest which nourishes the greatest number of noble and happy human beings"; and, again, "the final outcome and consummation of all wealth is in the producing as many as possible full-

breathed, bright-eyed and happy-hearted human creatures." From these axioms we deduce there are three tests of the wealth of a community—the growth in numbers of inhabitants, their health and their happiness. Numbers alone without the correlations of health and happiness are no indication of wealth, and that country which propagates an increasing quantity of deformed, imbecile and immoral offspring would be worse off than another country which produced a smaller number of healthy and happy children. If Dr. Taylor, therefore, quotes Ruskin in proof of the unqualified assumption that the wealth of a nation consists in the mere number of children it produces, he seems to the writer to be starting on a false premise. Quality, according to Ruskin, is at least as essential as quantity. His axioms, when applied to poor and over-crowded populations, absolutely discountenance the unlimited procreation of children, inasmuch as slum children cannot be "full-breathed, healthy and happy" and, in point of fact, they are as a class rickety, pale, unwholesome and vicious. The wealth of a country, tested numerically, must be further qualified by its ability to maintain the fresh generation at a standard of well-being in body and in mind at least equal to its own. Dr. Taylor has advanced the fallacy of partial quotation. Let us now add the rest of the passage from Ruskin as to the "full-breathed, bright-eyed and happy-hearted human creatures." "Our modern wealth," he writes, "I think, has rather a tendency the other way, most political economists appearing to consider multitudes of human creatures not conducive to wealth, or, at best, conducive to it only by remaining in a dim-eyed and narrow-chested state of being." Yet if the poorer classes are to go on multiplying children, according to Dr. Taylor's theory of what is their moral duty, they can for the most part swell the population only by degenerate and short-lived offspring.

The production of mere numbers of offspring, then, apart from their quality and destiny, is no true test of the inherent prosperity of a nation. Great reproductive activity is often, as in consumptives, a sign of degeneracy. The young generation, to satisfy the sanitarian and the economist, must be healthy and long-lived. To thrust feeble children under conditions of poverty into an already over-crowded community is to commit an act of selfish imprudence, the consequences of which must react on the parents in a manner not less disastrous than the evils attributed by Dr. Taylor to the artificial prevention. The ultimate population test is thus expressed by Ruskin:—(a) "The radical question is, not how much habitable land is in the world, but how many human beings ought to be maintained on a given space of habitable land." Suppose parents to be living in a certain spot that has reached its limits of supportable population. Can it be seriously maintained that the unlimited production of children would still be a moral obligation? Yet that is Dr. Taylor's proposition, unqualified by any conditions as to class in society, income, social circumstances, or facts of environment. If I interpret his

(a) "Ad Valorem." John Ruskin .1882, P. 162.

meaning aright, the plain bounden duty of all married persons, whether dwelling in rich houses or in sordid hovels, is to beget as many children as possible.

Beyond a doubt, poverty shortens life both for parents and for children. The remarkable statistics of Ansell show that the child of rich parents has a far greater chance of survival to adult, middle, and old age than the child of the poor. Dr. Drysdale, again, has shown that poverty is the main cause of premature death in old countries, such as those of Europe. (a) But the great proportion of increase now takes place among the poor, whose children are foredoomed to pay a terrible toll of suffering and premature death. Can a nation be really the richer for so vast a multiplication of feeble and shortened lives?

In a young country, such as a sparsely-populated colony, the mere multiplication of numbers may be a just measure of its prosperity. In an old and over-populated country it may be the reverse. At the same time in the more densely populated country the State is able to employ part of its surplus as soldiers and sailors, and capital to trade on the necessities of the struggling workers by grinding down wages to the lowest level.

*Assumption IV (or unsupported conclusion): That preventive practices are injurious to the moral and physical well-being of parents adopting them, as well as to the non-prevented children of such marriages.*

Doubtless now and then some of the pathological accidents mentioned by Dr. Taylor follow the use of preventive measures. They cannot, however, be common, and Dr. Taylor must forgive us for not attaching great weight to the two or three instances of acute mischief he is able to recall from his extensive experience. A certain number of persons are killed every year in crossing the street, apparently in obedience to some obscure law of average fatality that is inseparable from the majority of human actions and pursuits. To bring forward these exceptions would not be to establish any general causative relation between crossing the street and sudden death. Yet that is the kind of argument considered good enough by Dr. Taylor when he condemns preventive methods as physically injurious, because he has known one or two cases of peritonitis, and one of purulent infection follow their use. Nor can we accept more seriously his statements as to mischievous results of a chronic nature. Neurasthenia is the only specific instance he advances, and he ascribes that condition to "sexual onanism" and absence of the male element from the female economy. It is well known that neurasthenia may follow any excess, among the married or the unmarried, among those who desire conception or those who prevent it; but it is at least as common in the woman who has had many children as in any other individual or class of society. But if the object of all should be to raise up as many children as possible, continence—apart from its disciplinary effect—must be bad too, for it robs the community of possible accession to its ranks, and the State that demands children will bear an equal grudge against the continent and against the sexual onanist, for both conspire to prevent its heritage. The increase of juvenile crime, again, cannot reasonably be assigned to any limitation of the size of families. The only child, or the child of a small family, is always better looked after in mind, body and estate than the child who has eight or ten or more brothers and sisters, for reasons that are obvious. Besides, the overwhelming proportion of criminals is drawn from the class in which the limitation of families is least practised. Lastly, I ask Dr. Taylor if the vast majority of female troubles that come under his professional care, both in private and more especially in hospital practice, is not far more often due to multiple than to restricted child-bearing? From my point of view, an enormous proportion of the avoidable disease, insanity and crime that constitutes so great a blot upon our modern civilisation may be traced to the unrestricted multiplication of the children of the poor.

(a) "Population Question." E. C. Drysdale, M.D. Medical Society of London, October 27th, 1879.

Dr. Taylor has courageously attacked a delicate subject, but to my mind he has missed the real significance of the fall in the birth-rate during the last half century or so. He is a man of eminence in his profession, and of unquestioned candour and honesty of purpose. For all that, it is impossible to accept his views upon this most important matter without careful critical examination. It would be little short of disastrous were his particular views permitted to go out into the world unchallenged as those accepted generally by the medical profession.

One of the first questions that suggests itself in approaching this subject is whether the United Kingdom may not have reached its limit of supportable population. The growth of juvenile crime, of insanity, and of pauperism, and the increasing numbers of the unemployed working classes, seem to show that under existing social conditions a further increase in children becomes a positive disadvantage. The poor are now the prolific classes of the community, that is to say, the very persons who bring their offspring without stint into an environment that fosters pauperism and the other evils spoken of. The existence of so great a mass of avoidable misery and waste of life to my mind proves incontestably that under existing social conditions the supportable limit of population has been reached so far as the poor of our country are concerned. True, that limit may at any time be enlarged so as to admit of a happier existence for a greater number of the population. Some small relief may be effected by emigration, but after all said and done, that is only a temporary measure, which must come to an end sooner or later. The sound remedy will possibly or probably be found in laws that lead to greater equality in the distribution of wealth and of opportunity to the individual citizen.

Ruskin's view of the three remedies commonly suggested by the economist for over-population is much to the point. (a) He writes:—"These three are, in brief, colonisation; bringing in of waste lands; or discouragement of marriage. The first and second of these expedients merely evade or delay the question. It will, indeed, be long before the world has been all colonised, and its deserts all brought under cultivation. But the radical question is, not how much habitable land is in the world, but how many beings ought to be maintained on a given space of habitable land." The third expedient—discouragement of marriage—is not discussed by Ruskin. His answer, however, may be plainly inferred from his general views on the necessity of proper conditions of environment for every citizen. When Ruskin first published his book methods of prevention had not become widely known or advocated, or he might possibly have added a fourth expedient.

#### WHAT ARE THE INFLUENCES THAT GOVERN THE INCREASE OR DECREASE OF A HUMAN POPULATION?

In the lower form of animal life limitation of numbers is regulated by laws of which we know little or nothing. Darwin has somewhere pointed out that wood-lice multiply at such a rate that a single pair, if left alone, would in a comparatively short time be able to cover a continent. But in no locality do wood-lice obtain a preponderating numerical superiority. The herring, in common with most fishes, produces a countless progeny, but the herring tribe remains a fairly constant inhabitant of the sea. So, too, with rabbits and mice and other mammals. The rule in Nature appears to be that each species should produce a progeny vastly in excess of the actual needs of the case. Further, the limit of numbers seems to be fixed in some ill-defined but remorseless way. Why should not similar laws apply to mankind? At the present moment, as in past ages, he reproduces his kind in numbers vastly in excess of those that actually survive to the next generation. Lastly, man, from his special endowment of brain, may impose an artificial limitation upon child-bearing, and by this very intellectual limitation may

(a) "Unto this Last." By John Ruskin. Third edition. 1882. London. Pp. 102.

be constituting himself an unconscious instrument of evolution.

The population of England and Wales has taken about fifty-eight years to double itself. By the *law of population*, the latter increases in regular geometrical progression when the births exceed the deaths, and the ratio of the births and of the deaths remains constant. Were the population of England and Wales to go on doubling twice in 116 years, the figures would soon become stupendous. Farr, (a) dealing with this point, quoted a passage from an early edition of Malthus' "Political Economy." "If any person will take the trouble to make the calculation, he will see that, if the necessaries of life could be obtained without limit, and the number of people could be doubled every twenty-five years, the population which might have been produced from a single pair since the Christian era would have been sufficient, not only to fill the earth quite full of people, so that four should stand upon every square yard, but to fill all the planets of our solar system in the same way, and not only them, but all the planets revolving round the stars which are visible to the naked eye, supposing each of them to be a sun, and to have as many planets belonging to it as our sun has."

That preventive methods are increasingly practised among the better-to-do classes must be admitted. Some figures bearing on the relation between social position and fertility were given by Dr. J. Bertillon, (b) quoted by Dr. Newsholme at the meeting of the International Statistical Institute at St. Petersburg, September, 1897. The statistics relate to the births per 1,000 women, æt. 15 to 50, per annum, in different quarters of the undernoted cities.

Classification.	Paris.	Berlin.	Vienna.	London.
Very poor quarters ..	108	157	200	147

The stress of human suffering from increase of population beyond readily supportable limits must, of necessity, fall mainly upon the poorer classes. It demands a considerable exercise of faith to ask such poverty-stricken families to accept the teaching that the multiplication of children is one of man's highest moral obligations. Dr. Drysdale (c) speaks plainly enough on this last point as follows:—

"My argument is, then, as Sir Henry Thompson expresses it, that our farm is over-stocked with human animals, and that this is the only real cause of the permanent death-rate in our cities; and I contend that so long as the people of Great Britain continue to add to the population in the ratio of 362,923, as was done in 1877, or to have an annual birth-rate of 36 per 1,000, it is useless to expect anything from drainage schemes or the other expedients of public hygiene. Slums will always exist as long as people have such low wages that they cannot afford house-room enough for the over-numerous offspring they engender, a species of improvidence so conspicuous as yet among the poorer classes in the United Kingdom."

The stress of many children falls with terrible severity upon the mother where the family income is small. Take the case of the wife of the struggling clerk, the labourer whose work is inconstant, the poor curate, or the medical man in small practice, in a word, of any family belonging to the not-rich class of society where one child might be brought up well enough. Child upon child has to be fed, cared for, clothed, and educated, until the life of the mother is that of a slave, to say nothing of the tax of frequent maternity upon a body that is undermined with toil, privation, anxiety and short commons. The curate's lot in life is to

inculcate morals into the mind of his fellow-men. Can he, when a poor man, justify his position in multiplying his family indefinitely? Should he not either practise continence or decline the responsibilities of marriage, rather than drag a refined woman into a position of drudgery, broken health, and shortened life, while at the same time his numerous progeny are curtailed in necessaries of life, in comforts, and in education, so that in many cases private means must be eked out by the charity of strangers? The patient self-sacrifice of the mother of all ages, past and present, is written in blood on the pages of the world's history. It would be easy to draw a lurid picture of the difference between the many and the few children so far as the mother is concerned. Ansell, an acute observer, partially recognises the situation in the following suggestive passage:—

"In the upper and professional classes," he writes, "it is upon the men that the wearing toil and anxieties of life chiefly press, the women enjoying a comparative exemption from them. At the present age, when so many are striving to be foremost in the race of life, the husband is frequently, or it may be constantly, engaged in an arduous struggle to maintain or improve his position, and, whether successful or unsuccessful he, in too many instances, injures his health in the effort. Unless, however, he be exceptionally unfortunate, and at the same time have no friends to fall back upon, his wife and family will probably still be sufficiently supplied with the bare physical necessaries for healthy existence. With the labouring classes the case is very different. Among them the mental anxieties of obtaining a livelihood are rarely great enough to produce injurious results, but if the husband's wages are insufficient, the consequent physical privations tell upon the health of his family, his wife included, at least as much as, and probably more than, upon his own." (a)

But to review: We find a fall in the birth-rate—not as great as Dr. Taylor shows, nor confined to the married population, as he imagines—but still a fall, and we find that this fall is great among the upper classes of society, and probably affects to a certain extent the lower classes also. Now, what does this show? We reply that in this great competition the necessary limitation of future generations is showing itself most among the educated classes—a kind of intellectual limitation. This may be a matter of regret, especially if one adopts with Dr. Taylor the Spencerian doctrine that inherited qualities are transmissible, but it is not a new phenomenon. It is the result of the law that society tends to grow like a plant from below upwards. The Romans, whose patrician families were the most exclusive the world has ever seen, found that these families, far from increasing, had to be added to from time to time by recruits from the plebeians, if they wished to maintain an aristocracy in the State. Of five hundred of the oldest noble families in our own country, only five at the present day can trace their ancestry back, by the male line, to the fifteenth century. There has been no increase here, although our aristocracy have not minded marrying "beneath them" in a way that the Romans would never have dreamed of. A similar tale is told by the nobility of every modern European State. The "advantages" of civilisation do not conduce to rapid breeding of man; the more refined, the more comfortably circumstanced, the better educated classes have not the procreative genius of their less happily circumstanced fellows. In the case of ourselves at the present day, instead of a few aristocratic families enjoying these advantages, we have a large class of independent and professional men whose refinement and education is no whit inferior to that of the "governing caste." Therefore, as this class grows in the community, and it is daily growing, the curtailed birth-rate to which it gives rise affects a larger and larger number of persons, and the gross effect becomes more and more noticeable. It is interesting to speculate on the correlation of these two factors, increased

culture and diminished procreative fertility, but in a society where these obtain one finds the subordination of the carnal part of man to his intellectual part to lead to rebellion in the normal physiological functions—pregnancy becomes dystocia, menstruation—dysmenorrhœa, fertility—sterility. It is the principle of having the cake and eating it too, and whether the limitation of the offspring of the upper classes come from low sexual reproductive power, or from the direct intervention of his intellectual processes through celibacy, marital continence, or artificial prevention—or all these combined, as we find at present—these are only the expression of a great social law against which it is no use rebelling. The prosperity of trade has brought more and cheaper luxuries to the homes of the nation, so that the standard of material comfort has risen vastly; this increase of trade has required keener intellectual competition, and the brain has been taxed as against the body. Education has become a necessity of national existence, and education teaches people to think and look ahead. The great present stress in the grapple for bread is an intra-cranial stress acting in a well-fed body; but the stress is none the less keenly felt because it is primarily cerebral, but rather more so. The poor, the less intellectually developed, the serf, can always be trusted to breed; the sexual act constitutes one of their few relaxations—and pleasures. They follow their natural instincts. It is your brain-trained man who, like a wild animal in captivity, refuses to breed. At the risk of repetition it may be asked again whether this fall in the birth-rate may not be the expression of a natural law setting a limit to the too-great multiplication of a hungry, industrial, education-requiring community. It seems, indeed, to be the natural instinct of self-preservation asserting itself at the expense of the reproductive instinct, which two instincts Littré has shown to be the eventual basis of all impulses in ourselves. Dr. Taylor, rather inconsistently, regards these signs as a "handwriting on the wall," and at the same time denies that they are signs of decay. We are inclined to concur in the latter belief. We think they are due not to gangrene but to temporary congestion, and that appropriate treatment may be successful in warding off a fatal termination. He instances Japan as an old nation possessed of new life and activity—a second youth. I hesitate to think that he can attribute this in any way to the sexual morality of that country, which is notoriously deplorable, and her success as a *débutante* in "Welt-politik" must merely be in spite of, and not because of, her inter-sexual arrangements. But what is the result of the over-population of Japan, now that its eyes are opened by education, and that she has found her own strength? A "land-hunger," which Dr. Taylor extols, which shows itself by two bloody contests in a space of ten years, and which may end by inflaming the whole world! We hope for a more prosaic, if less eventful, solution to our own difficulties.

In the case of France there can be little doubt that the decrease in population is due to the adoption of preventive practices by all ranks of society. In other words, the views of the educated class with regard to the undesirability of multiple child-bearing have permeated to the labourers. That process, if continued, must mean fewer persons available for fighting and for the hard work of the State generally. The only remedy, so far as one can suggest, is that the State make the conditions of living easier by a readjustment of burdens, and the cheapening of the necessities of life, while life is at the same time made longer, sounder and more valuable by the development of medical science and administrative hygiene. A similar line of reasoning applies to the falling birth-rate of Australia.

And now to the solution. Dr. Taylor would have the State encourage the fathers of large, well-brought-up families by various aids, financial and educational. Unfortunately, we fear that the State would not be likely to take into consideration the quality of the bringing up of a family; the most that could be hoped for would be that the size of the family should be the qualification for assistance, and this, again, would really

be needed only in the middle classes. The poor have no direct taxation that could be remitted, and their education is already provided for. There is a good deal to be said for this plan, but it would be only an inducement after all, and might not meet with great favour in practice. Next, Dr. Taylor has a somewhat cryptic proposal for the State jealously to guard the earliest possible date at which productive work could be begun by those entering professions. We may say at once that such a matter is in the hands of the professions and the public, and at a day when the cry is all for a higher standard of preliminary education for the professions, it is not feasible. Then Dr. Taylor would make pregnancy less distressing by medical advice, diet, and management. Well, we all do our best as it is, and pregnancy is never likely to be other than a rather trying and painful business for the well-brought-up mother. Finally, Dr. Taylor makes a strong appeal to the forces of religion and morality to aid in putting down artificial prevention, though he is of opinion that occasional abstinence in married life is "allowable."

But is not this treatment merely symptomatic, and would not its effect, if successful, be rather to alleviate than cure the body corporate? And, again, might it not be possibly harmful by increasing the present undue competition of the upper middle classes? And yet again, would it, could it, be eventually successful in the face of natural laws? Unless some new distribution of wealth be unexpectedly brought about, or unless some new fiscal system give an impetus to trade like that given by Free Trade in the middle of last century, or unless some new sources of material wealth be tapped, mere increase in numbers is not wanted in this country for its own purposes. And this being the melancholy fact, the natural industrial conditions of demand and supply will combine to check over-production by some means or other.

In the long run the woman's innate desire to bear children must outweigh the difficulties and dangers incidental to pregnancy and parturition. At present, the prospect of not being able to bring up children weighs heavily on both parents or potential parents of the upper and upper middle classes. It is by means of this fear that the natural law of limitation of upper sections of a population is acting. Its expressions are found in late marriages, celibacy, marital abstinence, and artificial prevention. Now it is apparent that these methods are each and all the result of deliberate choice, that is to say, they are the results of the exercise of judgment and prudence, which, again, are the objects of all education and intellectual development to form. Judgment may decide rightly or wrongly, but it is in itself the highest product of mental training. Therefore, if we find judgment being exercised somewhat widely to limit the population, it must be because many of those in the best position to judge have decided that future increase is baneful. Now, if we admit that celibacy is preferable to incontinence, that late marriage is better than rash marriage, and that abstinence in married life is allowable, we are led to the conclusion that artificial prevention is the last resource available to that class, and it is a large one, of educated persons who desire the domestic advantages of marriage at an early period in their lives, and are not blessed with the power of restraint. That it is a commendable resource we do not argue, but that it is one to be faced fairly and squarely as certain to occur in the present state of society, and one that can be abrogated only by altering the conditions that lie at its root. It is no desire to "make the worse appear the better reason" that forces one into this position. It is no more a condonation of artificial prevention to point out its inevitability than it would be a condonation of prostitution to point out that it always has existed in civilised countries, and must do so if those conditions that produce it remain operative.

The recommendation of Thomas à Kempis, *frequentur tibi violentiam fac*, will indicate an alternative course for such as have not the gift of continence, but human

nature being what it is, there can be no doubt that while the incentive to prevention as to prostitution exists, there will be response to the invitation in certain quarters. We have already indicated our views on the exaggerated importance that we consider has been attached to prevention, as opposed to late marriage, as a factor in the decline of the birth-rate. But if prevention is a constitutional disease as we consider, nothing short of radical treatment will cure it, and in grave illness tinkering remedies are to be avoided. But, beyond the organisation of extensive schemes of colonisation, there remains another prime duty in this matter for the State to perform—that is, the prevention of marriage among criminals, lunatics, and diseased persons. The power of veto is asserted by the State in the regulation of marriage with regard to consanguinity; why should it not be equally enforced in the case of the other more serious conditions? Heaven knows we have enough of all of them at present, and that chronic inebriates, hardened criminals, lunatics, and tuberculous patients should be discharged from institutions with free licence to perpetuate their stigmata to generations yet unborn is a disgrace to a nation that calls itself civilised! Dr. Rentoul has proposed that by a simple surgical operation degenerates should be placed in such a position that the possibility of their propagating their kind should be for ever obviated. It remains to be seen whether such a suggestion will find support from society in general, but a check on the productivity of these classes would be an unmixed gain to any country in the world. While giving Dr. Taylor every credit that his courage deserves, we think that the crusade he advocates would be little effective unless the pressure that leads to the occurrence of these unfortunate conditions can be relieved by some such method as we have advocated.

On the whole, then, I find Dr. Taylor has brought forward little to support his assumption either as to the cause or the effects of the diminishing birth-rate. In a matter of such vast national importance, it is desirable that an exact scientific conclusion, that is to say, the truth, should be arrived at as nearly as may be. Possibly the end might be best approached by way of a Royal Commission of Inquiry, with a full examination of expert medical, social, and statistical evidence. In any case, I think the candid reader will agree with me that the causes of our diminishing birth-rate do not all lie on the surface.

The heads of my own conclusions may be thus briefly summarised:—

1. There has been a fall in the total birth-rate of the United Kingdom during the past half century, while there has been little change in the marriage-rate in the same period.
2. That the fall affects both legitimate and illegitimate births, and is therefore active outside the married state.
3. That the fall, roughly speaking, of the last thirty years was preceded by a proportionate rise during the thirty years before that again. Thus the average total birth-rate of 1840 roughly corresponds with that of 1900.
4. That in order rightly to appreciate the fall of the latter thirty years of the period mentioned, it is necessary to inquire into the causes of the rise in the first thirty years.
5. That the rise may have been due to the wave of national prosperity that passed over the country during the latter half of the nineteenth century, subsequent to—or because of—the introduction of Free Trade.
6. That the diminishing birth-rate may similarly be a delicate index of decreasing national prosperity.
7. That the fall may possibly be due to the fact that under present social conditions the maximum limit of supportable population may have been reached.
8. That the falling birth-rate may be partly explained by the increasing tendency to postpone marriage to a later age.
9. That a portion of the fall—not the main part—may be ascribed to artificial prevention of conception

practised chiefly among the better-to-do classes of the community.

10. That the general tendency among wealthy and patrician classes has always been towards lessened fertility and sterility (*i.e.*, apart from special preventive methods).

11. That increased celibacy must be taken into consideration, as well as the facilities and the relative frequency of divorce.

12. The constant drain of healthy soldiers and sailors lost in active service in various parts of the world must also be taken into consideration. (This point has not been raised in the foregoing article.)

13. That there is no trustworthy evidence to show that the practices of prevention lead to grave physical and moral evils in the parents, and in the non-prevented issue of such marriages.

14. That intellectual limitation of marriage fertility may be an evolutionary manifestation of the highest intellectual development, anticipating thereby the destruction wrought by natural laws upon superfluous individuals in the community.

15. That it is necessary to consider the quality as well as the quantity of the children brought into the world, as well as the chances of their survival to a ripe age.

16. That it is the immediate duty of the State to take steps to check the reproduction of criminals, lunatics, and of grossly diseased persons suffering from heritable maladies.

17. That an enormous proportion of the avoidable disease, insanity, and crime that constitute so great a blot upon our modern civilisation may be traced to the unrestricted multiplication of the children of the poor.

18. That the limit of population in the United Kingdom supportable under present social conditions may have been neared or actually reached.

19. That the soundest remedy may possibly or probably be found in laws that lead to greater equality in the distribution of wealth and of opportunity to the individual citizen.

## The Wightman Lecture

ON

## HEREDITARY BIAS

AND

EARLY ENVIRONMENT IN THEIR RELATION TO THE DISEASES AND DEFECTS OF CHILDREN. (a)

By R. CLEMENT LUCAS, B.S., F.R.C.S.,

Consulting Surgeon, Evelina Hospital for Children; Senior Surgeon, Guy's Hospital.

AFTER alluding in sympathetic terms to the circumstances which led to the foundation of the Wightman Lecture by Charles Wightman, Esq., Mr. Lucas proceeded as follows:—The truth of the general axiom that the child must resemble his parents will be universally admitted. The variations in the appearance of the offspring are frequently to be accounted for by the relative vigour of one or other parent. If all the strength be centred in one parent certain peculiarities are apt to arise. Thus, it has been observed in the case of the peerage that marriage with an only daughter is a common cause of the extinction of titles. With regard to longevity, all evidences point to the fact that length of life was being gradually extended by reason of a more widespread knowledge and observation of the laws of hygiene.

When we come to consider what diseases are actually hereditary, we are met with a difficulty at the outset. There are several diseases which were once thought to be of an hereditary nature which we now know are not so. As late as 1863, Dr. Sedgwick stated that pityriasis versicolor attacked all the males of a certain family. Those who believed in the influence of "diathesis" received a rude shock when Koch

(a) Abstract of Lecture delivered before the Society for the Study of Disease in Children, July 16th, 1904.

discovered the tubercle bacillus. The eyes of such distinguished observers of clinical facts as Sir Thomas Watson may even be closed from a too strict adherence to the diathetic theory. When I became attached to the Evelina Hospital for Children, I inquired into the family history of every case of tuberculosis in infants under the age of two, with the result that one or other parent nearly always suffered from phthisis. Are we, therefore, to throw over tuberculosis altogether as a diathetic disease? The so-called "types" of consumptives may be rather considered as an hereditary effect than a cause of the disease. If Cohnheim's theory be true, namely, that the bacilli have the power of penetrating into the germ or sperm-cell, then the outlook of the offspring of tuberculous parents is hopeless from the earliest period of existence.

Up to the time of the discovery of the specific bacillus by Hansen, in 1871, the hereditary nature of leprosy was firmly believed in, and even now, in certain parts of the world, segregation is still practised. But the Indian Commission failed to discover evidences of such heredity in more than 5 or 6 per cent. of the cases. The manner in which the disease is spread only remains to be further elucidated. Together with malaria the above affections must now be classed under the specific diseases.

Passing on to syphilis, which we know descends from one generation to another, we find that it very seldom goes on to the third generation. Mr. Hutchinson says that in eight cases of congenital syphilis he only met with one doubtful instance of transmission to the third generation, and I have notes of only one case. The term "transmitted" is better than "congenital," as better expressing our knowledge of its hereditary character. If both parents are affected with the disease the results are doubly disastrous for the offspring. Here we may note the fact that the later children of syphilitic parents are generally the more robust, in contra-distinction to those of strumous parentage.

There is one disease which is common in large cities, and which is responsible for much of the physical degeneration of the present day, and that is rickets. It is a purely dietetic disease, and it may be induced in any child simply by bad feeding. Its hereditary effects are well seen in puppies.

Now that a special diplococcus has been found in acute rheumatism, this disease also can no longer be considered as purely hereditary. Its antithetic counterpart, gout, can be produced in successive generations, for the children of gouty parents are generally brought up under the same conditions of affluence as themselves. It is possible, nay, even probable, that this malady will be found to be of an infective nature.

Congenital defects due to diseases of the nervous system are fairly common. Dr. Shuttleworth has found that in 20 per cent. of all cases of idiocy a history of mental disease in one or other parent may be obtained. The researches of Galton and Karl Pearson show that certain nervous diseases are not only hereditary but are transmitted in definite proportions to the sons and daughters of the parents so affected. Psychological tendencies are transmitted as well as physical qualities.

Hæmophilia is a disease which presents peculiar characteristics, inasmuch as it selects the males and yet is transmitted by the females. Other abnormal conditions appear to follow the same law, such as colour-blindness and polydipsia. Several ocular defects are distinctly hereditary, such as coloboma and nyctalopia.

It is when we come to external defects, however, that the influence of heredity is most clearly marked. As far as the skin is concerned, ichthyosis is transmitted through several members of the same family, and this for many generations. Psoriasis, in like manner, often runs in families. Such congenital abnormalities as supernumerary digits have been traced through five generations. With regard to hare-lip, I have previously recorded the fact that absence of the lateral incisor tooth in the mother is frequently the precursor of this deformity in the offspring, and I desire to add further

the observation that a feebly developed incisor tooth may, similarly, foreshadow the occurrence of hare-lip in the child. Many instances of the transmission of multiple deformities through successive generations have been recorded in the transactions of this Society, some of which have been conditions of great rarity.

The influence of intra-uterine amputation of limbs and other parts of the body, due to constriction by the umbilical cord, has probably been considerably overrated. There are many arguments which militate greatly against the acceptance of this view, and I would rather suggest that such deformities are due to errors far back in the process of development, perhaps of the nature of incompatibility between the germ and the sperm-cell. Once such a deformity has been well established, it is very difficult to eradicate. The "tyranny of ancestry" has first to be overcome, and this is not an easy process.

The influence of the parents upon the physical deterioration of the present day is even more important than the effects of bad food and surroundings upon the children themselves. Both the health of the parents and the nutrition of their offspring are matters in which the better observance of the laws of health cannot fail to react favourably upon the physical condition of the nation.

### SOME OF THE NEWER METHODS OF OPENING AND CLOSING THE ABDOMEN. (a)

By E. HASTINGS TWEEDY, F.R.C.P.I.,  
Master of the Rotunda Hospital, Dublin.

THERE is no more remarkable fact in the surgery of the present day than the want of unanimity existing as to the best method of opening and closing the abdomen in abdominal operations for pelvic diseases. The propriety of a vertical incision has only recently been called in question. It is still the operation of election among British surgeons, but on the Continent the transverse incision has largely superseded it. This plan, since my appointment to the Rotunda Hospital in November last, I have adopted in nineteen cases, and it is to the result of my observations in these that I now desire to draw attention.

Let me first say that the transverse incision is performed in two ways, different, but not antagonistic, and which of the two the operator adopts depends entirely upon the object he has in view. If his purpose be to obtain the most extensive view ever yet attempted of the pelvic regions, he should proceed as Mackenrodt does in his very radical operation for uterine cancer. The skin, fascia, recti muscles and peritoneum are divided by a long, slightly curved incision, close to and above the pubes; portions of the oblique muscles at either side will probably also be severed, and by this an extraordinarily clear view and extended field will be obtained in which to operate. The incision is a formidable one; necessitating as it does the severance of the muscular supports of the abdomen, the proper union of which can never be hoped for, a weak scar is more than likely to result, and save for the removal of cancer, I know of no justification for such an incision. If, on the other hand, the object is not primarily that of obtaining an extensive view, the second method will be found applicable, and, I believe, preferable in many cases in which a vertical incision has heretofore been made. In it a transverse and slightly curved opening is made at

(a) Read before the Obstetrical Section of the Royal Academy of Medicine in Ireland, Friday, April 15th, 1904.

the margin of the pubic hair, through skin, adipose tissue, and sheaths of the recti. These structures are raised as a thick flap above and below the incision, from the muscles lying beneath them. The division between the recti can now clearly be made out; the latter are separated and the abdomen opened in the usual manner. The advantages of such an incision are manifest. In the first place it runs in the direction of the elastic fibres of the skin, as a rule the parts fall naturally into position on the completion of the operation, and the fear of hernia is reduced to a minimum, the severed aponeurosis is, throughout the greater part of its course, protected by the muscles, and it is only the transverse slit extending between these that could by any possibility permit of the escape of the abdominal contents. The application of a few interrupted sutures, superficially placed in the muscles, sufficient to keep them in apposition until adhesions form between them and their overlying fascia, will effectually prevent the occurrence of hernia. The scar left after such a wound has no tendency to spread. It runs in the direction of the natural wrinkles of the abdomen, and has the added advantage of being covered by the pubic hair.

I have on several occasions curved the incision to a considerable degree, in order to obtain more room. This I now look upon as a procedure to be avoided if possible, as it adds to the unsightliness of the scar. This method of operating should be confined to the less severe abdominal sections. In suitable cases, however, it will, I am sure, steadily gain in favour. On one occasion the fascia did not come easily together, and excessive strain on it had to be prevented by keeping the patient's legs flexed for a few days. One case alone showed slight indications of a stitch abscess at the extreme end of the incision; the operation was undertaken for the cure of an old ventral hernia. It was impossible to sterilise the skin efficiently. The woman suffered from a severe bronchial cough of a chronic character, and as a further complication a pneumonic area of dulness developed after the operation. Finally, I may add that the incision does not lend itself well to the employment of an abdominal drainage-tube.

Hernial formation is unfortunately a very common sequela of abdominal operations. In no less than six instances I have opened the abdomen within the past four months for the relief of this complication. Of these, two were operations not performed in this country, and one of them was so remarkable that it is worthy of being recorded.

The woman entered the hospital some four weeks ago, suffering from the effects of a former abdominal section performed eight years previously. On the evening of her arrival in hospital, during a fit of coughing her abdomen ruptured, and masses of intestines extruded on to the skin, the pubic hair, and sheets. A full hour elapsed before an operation for her relief could be effected, but notwithstanding, I am happy to say her recovery has been uneventful.

The prevention of hernia, is, I think, entirely dependent on a proper *technique*: being followed in the closing of the abdominal wound, in the accomplishment of which the main objects should be strict asepsis, careful apposition of the more important abdominal layers, and lastly the prevention of subcutaneous hæmorrhage. The attain-

ment of these ends will always remain doubtful in the practice of those surgeons who employ the through-and-through suture.

It seems to me a safe precaution to close off the peritoneum (in the first instance; this can be very readily accomplished by means of a continuous suture of fine silk. This No. 2 silk with us antiseptically prepared by being boiled on two occasions separated by an interval of twenty-four hours in 1 in 1,000 corrosive sublimate solution. The object sought by such preparation is to render the silk actively inhibitory to the growth of germs with which of necessity it must come in contact until such time as the phagocytic action of the tissues can exert their full power. Whether the posterior sheaths and recti muscles should be sutured is still a debatable point. For my part I believe such a procedure is not only unnecessary but positively harmful. The union between muscular structures is proverbially weak, and sutures piercing at right angles to their fibres must impair their vitality by strangulating portions of their vascular and nervous supply.

It is no doubt essential to keep the muscles in close apposition, and this can with certainty be done by properly suturing their external sheaths. To attain this end I was formerly in the habit of uniting the sheaths by interrupted sutures of silk-worm-gut placed in mattress fashion after the manner advised by Kelly. This proved most satisfactory, and has only now been abandoned by me in favour of the fine continuous suture of silk for the reason that the latter can be applied more rapidly. The method of suturing above described will almost certainly protect against future hernia, and I need hardly say that in bringing it to your notice I make no claim to originality.

The closure of the skin wound I have not as yet dealt with, and it is in connection with this that I desire to call attention to my recently introduced method which, so far as I know, is novel. I pass a subcutaneous silk-worm-gut suture immediately beneath the skin in the usual manner and thread either end through a perforated leaden plate similar to the one I now show. These plates are cut out of ordinary roof lead; in width they measure about two inches, while its length is made to correspond to that of the incision. The lead can be perforated opposite the ingress and egress of the suture by means of a strong surgical needle. Through these the ends of the suture are passed, and having been drawn taut are tied together over the plate. The plate should be sterilised, and both it and the skin be in a perfectly dried state before its application. Aseptic dressings are placed over the plate, and an abdominal binder applied in the usual manner, the parts being left undisturbed for foretun days. On the expiration of that time the dressings can be removed and will be practically unstained. The suture is now cut and the leaden plate lifted off. It does not adhere to the skin, but will be found to act after the manner of a smoothing iron in procuring exact apposition of the opposing edges, and preventing over-riding of surfaces. The plate affords a ready means of preventing the suture slackening, and does not permit the wound to pucker. Moreover, I feel convinced that the lead itself exercises a favourable influence on the healing process, for I cannot otherwise account for the perfection of the scar.

## The Out-Patient Departments.

### TOTTENHAM HOSPITAL.

#### *Dermatological Cases under the Care of*

G. NORMAN MEACHEN, M.D., M.R.C.P.

#### CASE I.—*Lichenoid Transformation of Scratch Marks.*

—The patient, a married woman, æt. 31, had suffered from an irritable eruption for about six months. Her general health had not been affected, and she had had no previous illnesses. On examination, there was discovered a profuse eruption of lichen planus, the lesions being typically flat-topped, shiny, and more plentiful upon the lower extremities, where their colour was somewhat dusky. No lesions were observed upon the buccal mucous membrane. There were several scratch-marks visible, as the rash was very pruriginous, and upon some of these it could be seen that the linear streak made by the finger-nails was thickly set with small papules showing all the characters of lichen planus. One recent scratch upon the right hand, which the patient stated was inflicted accidentally, also showed the papules in place of the usual superficial blood-crust which forms under normal circumstances as the result of a deep scratch.

Dr. Meachen remarked that the so-called lichenoid transformation of scratch-marks, occasionally met with in this disease, was a most interesting feature. As far as the pathology of the affection went, the condition was, in itself, an evidence that the morbid process was prone to attack those areas of the skin whose resistance was lowered or whose vitality was impaired. He instanced the case described by Dr. West, in which the lichen papules appeared in a scratch-mark inflicted by a kitten before any other part of the eruption appeared elsewhere. The only remedy which really did seem to possess a specific influence upon the course of lichen planus was arsenic, and this patient was therefore put upon three minims of Fowler's solution, thrice daily, to commence with. A weak tar lotion was ordered for local application.

CASE II.—*Prurigo Mitis.*—A little girl, nearly three years old, was brought to the hospital with a very irritable eruption which the mother stated had been present for about eighteen months. She had attended other hospitals. The child was said to be in good health, although its sleep was much disturbed at night by the irritation.

On inspection, the skin over the lower part of the trunk, thighs, and legs, and to a lesser extent over the chest and upper extremities, was covered by a profusion of small conical papules, many of which were surmounted by a blood-crust, indicating the irritable character of the eruption. The extensor surfaces were more affected than the flexor. On passing the hand lightly over the areas the firm nature of the papules could be felt. There were no urticarial wheals nor were there any eczematous patches anywhere. There did not appear to have been any great error in the dieting of the child, for the mother had endeavoured to carry out previous instructions. The bowels were habitually irregular in their action. The glands in the groins were not enlarged, and no other member of the family had ever suffered or was suffering from a similar complaint.

The diagnosis of this case rested upon the papular nature of the eruption, the absence of wheals or exudation, and its chronicity. Itching was always a well-marked symptom of the disease, and the scratching which it evoked was responsible for the secondary lesions which were plentifully seen in the present case. The affection usually commenced at or about the end of the first year of life, and sometimes persisted for several years. Geographical conditions and racial characteristics seemed to have an important bearing upon the prevalence of the disease, for it was distinctly rare in America and it was said to be relatively more frequent among children of the Jewish community.

The treatment of this affection sometimes taxed the ingenuity of the physician to the utmost. Sedatives

were often required at night, a draught of chloral and bromide being suitable for this purpose. Constitutional and hygienic treatment was necessary in the majority of cases, plenty of fresh air and good plain nourishment being enjoined. Cod-liver oil and malt internally was indicated in marasmic infants. To relieve the irritation, lotions of carbolic acid, 1 in 80, or of creolin, 1 per cent., were useful. This child was given 5 min. of the tinct. cinchonæ in the mist. mag. sulph. cum rheo, three times a day.

CASE III.—*Eczema of the Face with Catarrhs of Mucous Membranes.*—A little girl, æt. 3, had suffered from right otorrhœa for a fortnight, and was brought by her mother to the skin department with a "breaking-out" upon the face. A few days before this the right eye became inflamed. There was a typical weeping, papular and crusty eczema of the face, chiefly limited to the right side, but extending downwards a short distance upon the neck. The auricle was also involved, and there was an acute conjunctivitis with photophobia upon the same side.

The association of eczema in young children with various catarrhal affections of the mucous membranes was not unfrequently observed. A running at the nose was prone to lead to an eczematous dermatitis of the upper lip and adjacent parts of the cheeks, while a purulent discharge flowing from the external auditory meatus often determined the appearance and the distribution of an eczema in the immediate vicinity of the affected ear. In such instances the skin affection was clearly secondary to the other catarrhal conditions, and when these were cured the skin got well. Sometimes, however, parents will persist in the statement that the eczema appeared first. Believing, as we do, that eczema is a true cutaneous catarrh, whether it be produced by micro-organisms or not, it is not inconceivable that this morbid process should affect several anatomically allied tissues at the same time. Only upon this theory can we account for the appearance of simple or a phlyctenular conjunctivitis coincidentally with an acute facial eczema. Regarding an otorrhœa in the light of an exciting cause of the skin affection, it is useless to expect much improvement in the latter until the aural discharge be cured.

## Transactions of Societies.

### EDINBURGH MEDICO-CHIRURGICAL SOCIETY. MEETING HELD JULY 6TH, 1904.

PROFESSOR CHIENE, C.B., President, in the Chair.

MR. H. J. STILES showed a girl, æt. 7, on whom he had operated for a large abdominal tumour of long standing. It occupied the upper zone of the abdomen, and while its lower margin reached below the umbilicus, it was chiefly epigastric and extended below the left costal margin. At first sight it resembled a pancreatic cyst or a large hydronephrosis, but as it could be freely moved from below the ribs, and from one loin to the other, it was concluded that it was unconnected either with the kidney, loin, or pelvis. Eventually a probable diagnosis of mesenteric cyst was arrived at, and this was confirmed at the operation, when the cyst was found to be firmly adherent to the muscular wall of the intestine. It was formed of fibrous tissue, covered with peritoneum and lined with endothelium, and had probably developed from one of the lymphatics.

DR. EDWIN BRAMWELL showed (1) an interesting case in connection with Edinger's theory of the etiology of tabes. The patient was a watchmaker who had had syphilis ten years ago. He had dimness of vision and loss of accommodation in the right eye, and Argyll-Robertson pupil in the left eye. There were no other signs of tabes. Edinger's view of the etiology of tabes was that, while a specific infection is the predisposing cause, any excessive functional activity precipitates the lesion. In this case the patient habitually used his right eye a great deal. (2) A case of chronic poliomyelitis in a hammerman. The patient had

gradually progressive weakness of the right arm of three years' duration. Six months ago he had stopped work, and since then the condition had undergone arrest. There was marked atrophy of the upper arm, the biceps being very feeble, the upper part of the trapezius atrophied, its lower and middle parts gone. The supinator longus was also much wasted, and both the latissimi dorsi failed to react to electricity. The deltoid and triceps were intact. It was evident that the muscles involved by the atrophy were those used in the patient's occupation.

Dr. ALLAN JAMIESON showed a case of acne rosacea of the hypertrophic type affecting the nose. The condition had been much improved by slicing off thin layers of the superficial textures under adrenalin and cocaine. (2) A case of lupus vulgaris of five years' duration affecting the nose, upper lip, hard palate and gums. Treatment by the X-rays had had little effect, but the use of radium bromide for twenty-two hours in all had produced an almost complete cure.

Mr. F. M. CAIRD showed (1) a patient after removal of a large right-sided renal tumour (nephroma). The patient's hæmoglobin was down to 48 per cent., he had heart disease, bronchitis, and ascites, and was in a very precarious condition before operation. He had enucleated an enormous tumour of a somewhat rare nature, growing as it did from the adrenal and swallowing up the whole kidney. (2) A woman, æt. 54, who had heart disease, ascites, and bronchitis, and symptoms of chronic obstruction, from whom he had removed a carcinoma of the transverse colon. The tumour was the size of the fist, and had been taken away along with a piece of the bowel, the ends being reunited by end-to-end suture. (3) Coxa vara in a boy, æt. 7, who had had difficulty in walking for two years. He had a peculiar swinging gait, the hip-joints were freely movable, but abduction was impossible, and skiagrams showed that the neck of the femur formed almost a right angle with the shaft.

Mr. J. W. DOWDEN showed a man, æt. 60, two years after an extensive series of operations for epithelioma of the floor of the mouth, and (2) a patient two years after removal of epithelioma of the lip.

Dr. R. A. FLEMING showed a patient who, since 1901, had been subject to curious attacks of a sensation of suffocation whenever she laughed or coughed. Nothing could be found to account for the spasm, which in some ways resembled whooping-cough, there being a short, gasping inspiration and a long wheezing expiration with a cough between the two phases. The condition was obviously nervous and great benefit had followed the use of high frequency currents, though other remedies had previously done little good.

Mr. J. M. COTTERILL showed (1) a man, æt. 52, who had had a tumour of the liver for three years. The probable diagnosis was sarcoma, but removal of a piece of the growth for microscopic examination had revealed nothing definite. A month ago the patient had developed a large swelling of the epididymis, which suggested that the condition might be syphilitic. (2) A boy with congenital deformity of the ear, jaw, and face, and spina bifida.

Mr. A. SCOT SKIRVING showed a girl with peculiar arrest of development of the fourth metacarpal bone.

Sir THOMAS R. FRASER gave a communication on  
A CASE OF COMPLETE TRANSPOSITION OF THE VISCERA WITH CEREBRAL TUMOUR AND OTHER PATHOLOGICAL CONDITIONS.

After briefly referring to another case of the same condition, which had been under observation on a previous occasion, a description of this case, that of a man, æt. 24, in which the diagnosis had been made during life and confirmed after death, was given. The patient was already aware of his peculiarity, his attention having been drawn many years ago to the fact that his heart was beating on the wrong side. In consequence of this, he was seen by Dr. Bruce, of Glasgow, who had made the diagnosis and described the case in the *Glasgow Medical Journal* for 1895. He was admitted to the Royal Infirmary on account of pyuria and paroxysmal headache. On physical examination,

a complete transposition of all the viscera—heart, stomach, liver, spleen, and large intestine—was made out. He also had a supernumerary thumb on the right hand. The urine contained pus, but no tube-casts, and the diagnosis of pyelitis was made. Examination of the nervous system revealed the fact that he was right-handed, and that he had congenital anosmia. The headaches were of such a nature as to suggest intra-cranial pressure, but the diagnosis was not at first clear, and was only confirmed several months later when he returned to the Infirmary on account of their increasing severity, associated with blindness. He died somewhat suddenly without any further definite cerebral symptoms. On post-mortem examination a cyst, about the size of a marble, was found in the centre of the brain pressing on the left foramen of Monro, and the condition of the viscera referred to above as ascertained by clinical examination was confirmed. The rarity of cyst in this position was referred to, and the literature of transposition of the viscera shortly discussed. While many cases were upon record, in only a few had the diagnosis been made ante-mortem. A minute anatomical investigation of the viscera had been carried out under the supervision of Professor Cunningham, and beyond the fact that there was a complete transposition of the organs extending to the minutest arteries and nerves, kidneys, pancreas—in short, to all the structures of the body—no anatomical peculiarities had been detected.

The paper was discussed by Dr. EDWIN BRAMWELL, who mentioned a case of cyst of the brain in exactly the same locality, which had come under his notice some years before.

Dr. W. G. SYM read a paper on

METASTATIC GONORRHOEAL CONJUNCTIVITIS,

Ordinary conjunctivitis occurring in the subjects of gonorrhœa was a very acute inflammatory process indeed; it began unilaterally, and the second eye was infected from the first. There was great chemosis, profuse discharge, commonly ulceration of the cornea, and numerous gonococci were present in the pus from the eye. The symptoms of the metastatic form were quite dissimilar; it was more allied to the joint affections and iritis of gonorrhœa, was subacute with slight watery or mucoid discharge, few gonococci; while ulceration of the cornea was rare. He had seen two cases only, briefly as follows:—(1) A man had had gonorrhœa three months previously and the discharge had stopped three weeks before the eye symptoms set in; along with the conjunctivitis several joints became painful, these symptoms improved and then there was a relapse. There was moderate injection of the conjunctiva with secretion of watery muco-pus, a small peripheral ulcer of the cornea and some hyperæmia of the iris which might occur along with any corneal ulcer. The left ankle and wrist were inflamed. No bacteriological examination was made. (2) A male who had suffered from gonorrhœa for three weeks, but never very badly, as he had been carefully treated from the first. The possibility of direct infection was excluded. Conjunctivitis had been present for three days, but was not very severe—very much resembling a moderate case of ordinary catarrhal conjunctivitis. The ocular conjunctiva was injected, and the lids swollen. The patient complained of no rheumatism, but on being questioned admitted that he had had pain in the shoulder for about twenty-four hours, to which, however, he had paid little heed. Subsequently, other joints became involved. A few gonococci were found in the conjunctival secretion, though with some difficulty. Recovery under the use of sublimate lotion and protargol was complete, but the joints were somewhat obstinate. Direct infection here was excluded by the care which the patient had taken, the bilateral onset, and the presence of joint effusion. These two cases were the only ones Dr. Sym had met with, and the condition was not even referred to in most of the text-books. It had, however, been discussed at the Ophthalmological Congress at Utrecht, and at the British Medical Association Cheltenham meeting. The origin of the condition was uncertain; probably it

was due to the bacterial toxins rather than to the bacteria themselves, as dead cultures of gonococci produced a mild conjunctivitis in animals. Probably the disease was not very rare, and it was well that ophthalmologists and surgeons who saw many cases of venereal disease should bear in mind its existence.

Dr. LOGAN TURNER read a paper on

OBSERVATIONS ON THE OPERATIVE TREATMENT OF CHRONIC SUPPURATION IN THE FRONTAL SINUS.

The author first pointed out that a great deal had been written upon this subject, and that probably the literature would be still further increased owing to the fact that we had not yet arrived at a perfectly satisfactory method of dealing with these cases surgically. Relapses not infrequently occurred, a considerable number of post-operative fatalities had been recorded, and the question of disfigurement was a prominent one in connection with the removal of bone in the region of the forehead.

Many operations had been devised, but whatever might be the *technique* of the operation performed, there were two principles underlying the various methods of procedure. First, opening the sinus through its anterior wall, curetting the cavity and draining into the nose, an operation associated with the names of Ogston-Luc; secondly, obliteration of the sinus by the removal of the anterior bony wall of the cavity only, or of its anterior and inferior walls. Evidence was then brought forward to show that opening and draining the sinus was, in a large number of cases, an unsatisfactory procedure. Anatomical reasons were to be found in the varying extension of the sinus upon the forehead and into the roof of the orbit, and also in the recesses and partial subdivisions of the sinus which might be completely overlooked through a moderate-sized opening made in the anterior wall of the cavity. Again, the inability to deal thoroughly with the ethmoidal cells so frequently affected along with the frontal sinus led to re-infection of the latter cavity. Statistical tables were shown illustrating the failures that had occurred in the hands of different surgeons and a table was given showing how much more frequently death had followed the operation of opening and draining the sinus than when the obliteration method had been carried out. The obliteration operation was then considered, and the better results thus obtained were demonstrated. The question of comparative disfigurement in the two operations was discussed and illustrated by results of operative interference. Finally, the Killian operation was described and its merits discussed, and the hope was expressed that possibly this procedure might come to be recognised as a distinct advance in dealing with these troublesome cases. The paper was illustrated by a large number of lantern slides and stereoscopic photographs.

REPORT OF THE OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM ON SIGHT-TESTING BY SPECTACLE-MAKERS.

The Ophthalmological Society of the United Kingdom, having had its attention called to the fact that the Worshipful Company of Spectacle-Makers proposes to include the subject of sight-testing in the examination for its diploma, and to give certificates of efficiency therein, wishes to express its opinion that, while approving of any measures which tend to increase the efficiency of opticians in their technical work, it considers that it would be misleading and dangerous to the public to countenance any proposal to certify as competent to advise and prescribe for defects of vision anyone who has not had an efficient medical and surgical training. A diploma such as the Worshipful Company of Spectacle-Makers proposes to grant may lead the public to believe that its possessor is competent to diagnose and treat diseases of the eye, and thus grave consequences might follow. Errors of refraction often occur in association with diseases of the eye. The mere correction of the former by means of spectacles would ignore a condition which might destroy sight, or even leave the life of the patient in danger.

Moreover, many errors of refraction can only be accurately measured after the local use of a drug, which should only be employed or prescribed by a medical man, since its indiscriminate use is calculated to excite one of the gravest diseases to which the eye is liable. Finally, on general grounds it is undesirable and dangerous to encourage the public in the belief that affections of any organ of the body can be safely treated by anyone unacquainted with its anatomy and physiology, and with the various morbid conditions to which it is liable.

(Signed) JOHN TWEEDY,

## British Health Resorts.

[BY OUR SPECIAL MEDICAL COMMISSIONER.]

### II.—ILFRACOMBE.

ILFRACOMBE is the largest and most popular health station and holiday resort on the north coast of Devon. It lies in a natural basin and is surrounded by high treeless moorlands, except on the north side, which lies open to the Bristol Channel. On the east, protection is afforded by Hillsborough Hill, some 450 feet in height, while to the west stretches a succession of undulating hills. The southern limit of the urban sanitary district of Ilfracombe is constituted by a range of hills 600 to 800 feet in height. The marine slope ends more or less abruptly in rugged weather-worn cliffs. The soil is thin and the rocks are wholly shale over sandstone and grit. There are a few pockets of mountain limestone and a small amount of poor clay.

The climate is particularly mild and equable, due, in great measure, it is claimed, to the influence of the Gulf Stream. The Royal Meteorological Society have obtained a continuous series of records since 1875, and according to the last report of the medical officer of health, the average winter temperature is 44.9°; for the months of February, March, and April, 44.6°; and for summer, 57°. The daily range of temperature is 8.5°. Dr. E. J. Slade King's report also states the birth-rate as 17.9 per 1,000, and the death-rate 14.1 per 1,000; but excluding the deaths of visitors the true death-rate appears as 11.3 per 1,000. The infant mortality is equivalent to 134.6 per 1,000 born. The district shows no marked prevalence to special forms of disease. Phthisis is comparatively infrequent. A system of voluntary notification of consumption is in use. The isolation hospital is modern and well-equipped, but scarcely sufficiently distant from the newer part of the town. The sewerage and drainage have recently been much improved, and the new water supply which is to be drawn from Challacombe, on Exmoor, appears from our analysis to be of great purity and well suited for drinking purposes. The inhabitants are chiefly engaged in occupations dealing with the provision for visitors. There are large numbers of apartments and many good boarding-houses, but first-class hotel accommodation is limited. The marine walks and hill paths, together with the public pavilion, are designed to meet the wants of the holiday-maker rather than of the invalid. The beaches afford no sandy stretches and are generally unsuited to the requirements of children, but afford facilities for convenient bathing stations. There is also a well-equipped public swimming bath.

Ilfracombe is a particularly good centre during the summer season for coaching and steamer excursions. It is thus readily seen that the attractions of the place are more likely to appeal to the young and vigorous than to the aged and enfeebled.

Ilfracombe, however, can offer not a few conveniences for the invalid. Its equable and bracing climate, its easily accessible walks with numerous shelters and resting-places amidst picturesque surroundings, make for the reinvigoration of convalescents and the recreation of the overworked. Certain cases of neurasthenia could be sent here with advantage. It claims to take rank as a winter resort, but from all we

can gather the prevalence of wind would militate against its usefulness for many cases at that season of the year. Access to Ilfracombe may be obtained by a number of different ways. A direct service from London (Waterloo) is provided by the London and South-Western Railway, and during the summer months a through carriage is run from Paddington by the Great Western Railway. Visitors from the North and Midlands travel to Bristol, from whence they continue by rail on the G.W. system, or during the summer months by steamer. Visitors from Wales may often conveniently cross the Bristol Channel in well-equipped steamers starting from Swansea. In the summer season the comparatively vigorous traveller may obtain a pleasant mode of access by travelling to Minehead on the G.W.R., and thence proceeding by coach through the pleasant resorts of Porlock and Lynton to Ilfracombe.

We strongly recommend this bright, bracing and attractive town, which is rich in facilities for the building up of the natural powers of resistance, to the attention of physicians and all interested in what we may term the "prophylactic influence" of a wisely selected holiday resort.

For many useful particulars see:—

(a) Medical Officer's Report of the Urban Sanitary District of Ilfracombe.

(b) An Official Guide to Ilfracombe is also published by The Health Resorts Association, 2 Gray's Inn Road, High Holborn, London.

(c) A useful handbook to Ilfracombe and district is issued by Messrs. Ward, Lock and Co., London.

### Continental Health Resorts.

#### THE BRENNER-BAD IN TYROL.

AN AUSTRIAN HEALTH RESORT NEW TO MANY OF OUR READERS.

THIS Alpine Spa, although at an elevation of almost 4,000 ft. above ocean level, is really very accessible. It is located immediately on the main line of railway running from Italy to Germany, six hours from Verona, five hours from Munich, and by express trains only an hour and a half from the central and junction station of Innsbruck.

This route, either southward or northward from Brenner, is one of the most picturesque of the famed Southern Railroad of Austria, noted alike for the novelty and grandeur of the countries it traverses and for the comfort of its carriages.

Of itself, the Brenner ranks deservedly high amongst the most celebrated of Alpine Passes. The mineral springs, baths, and hotels are located at the most beautiful position in this notable Pass, and at the centre of attractive excursions by foot, carriage, or rail. Pleasant hill-sides and woods are around the place, rich pasture-lands, swiftly flowing streams, and exquisite Alpine flora. It has thus many attractions for the artist and botanist.

For those seeking a summer sojourn with a temperature unusually mild and agreeable for so high an altitude, and for those desiring a rest or air cure, the excellent hotels and novel surroundings at Brenner-Bad have many inducements. Completely sheltered by heights from northern and easterly winds, it lies open southwards to the glorious Italian sun, in this respect differing greatly from many mountain health-resorts, which are usually in confined valleys. At Brenner is a constantly changing air-current, revived and aromatised by passing through and over fields, forests, and sunny peaks.

Quite apart, therefore, from its medicinal waters, Brenner-Bad has good claims for favourable attention. Its Mineral Springs, too, have enjoyed for several hundred years local celebrity because of their unquestionable efficacy in even chronic cases of gout and rheumatism; in many cases of diseased limbs their use is specific.

In the year 1608, a prominent and patriotic patrician of the ancient city of Sterzing bequeathed to his ancestral town the bath buildings he had erected for

public benefit at Brenner. Hotels and other accommodations were gradually added thereto by the municipality of Sterzing which owned these Thermal Springs. In 1899, the property was transferred to the present company, who have erected up-to-date hotels, and new bath buildings, containing the latest and most approved appliances for hydrotherapeutic and electrotherapeutic treatment; so that to-day the Brenner-Bad offers the combined advantages of an exceptionally fine Alpine "climaterique cure" with a very valuable "mineral-water cure" added, combined with modern comforts, good resident medical attendance, and beautiful Tyrolean surroundings, picturesque and novel in life and characteristics.

Professor Barth's analysis of the solid residuum of 1 lb. (6,780 grains) of Brenner-Bad mineral water:—

Sulphate of potassium .. ..	0,128862

### France.

[FROM OUR OWN CORRESPONDENT.]

PARIS, July 17th, 1904.

#### A NEW SIGN OF PLEURITIC EFFUSION.

PROF. GROCCO has published a new symptom of pleuritic effusion, easy to discover and of considerable value.

When a liquid of any kind is present in the pleura, a dull zone of triangular form can be found by percussion on the opposite side. The internal edge corresponds to the vertebral spinous apophyses; the base, from one or two inches in length, corresponds to the point where the normal thoracic sonority ceases, while the external edge follows an oblique ascending line, intersecting the internal side of the triangle at the upper limit of the effusion. This dull surface varies in extent with the quantity of liquid, and diminishes when this liquid tends to absorption. The dullness is more marked near the median line and the base of the triangle; a decrease in the vesicular murmur is also perceived by auscultation.

Badnel and Siciliano experimentally studied Grocco's symptom and its varieties by slowly injecting liquid into the pleural cavity of corpses, and gave the following explanation—the pleural *cul de sac*, distended by the effusion, is displaced and, passing in front of the vertebræ, exceeds more or less the median line; it thus pushes before it the mediastinum into the opposite side of the thorax. At this point dullness will consequently exist, provoked by the presence of liquid contained in the distended pleural *cul de sac* and the displaced thoracic organs. The compression by the displaced heart of the lung, which becomes more dense, also favours the production of the dullness.

The mediastinal organs are much more displaced by effusions on the right side than on the left. The aorta, as everyone knows the most important organ of the mediastinum, is, when in normal position, on the left of the median line. Consequently in effusion into the right pleura, the artery becomes easily displaced towards the left, bringing with it the whole mediastinum; where the left pleura is affected, the aorta can only be pushed a little towards the right, while the other organs sliding over it fell to the right side of the thorax.

The new clinical sign described by Grocco is valuable for diagnosing slight effusion into the pleura. It permits particularly to distinguish spleno-pneumonia from pleurisy, which reveals itself by identical physical symptoms, and cannot be suspected until after several small operations with the exploring needle have remained without result; the absence of the triangle of Grocco will put down to spleno-pneumonia the symptoms attributed at first to the existence of a pleural effusion.

#### ADRENALIN.

A very interesting study of adrenalin by H. J. Noé, appears in the *Archives Gén. de Méd.* for June 28th, 1904, in which a full statement is made as to the history, the process of extraction, the physical and chemical properties, and the constitution of adrenalin, together with a process for the colorimetric estimation of the substance. In January, 1901, Takamine first announced his discovery in the suprarenal capsules of the base, to which he gave the name adrenalin. Later in the same year Von Furth perfected his process for the preparation of suprarenin, and obtained an iron compound in the form of an amorphous violet powder, and after elimination of the iron by acid he produced a substance which he declared was the same as Takamine's adrenalin.

Various considerations lead to the supposition that the name adrenalin does not correspond to products always identical in themselves and well defined chemically. These considerations led M. Canjon in his thesis read before the Paris Faculty of Medicine to state that "all these products differ considerably in their physiological action and in their toxicity. The different methods of extraction give substances very dissimilar, and to such a degree has this come that very experienced practitioners who have had occasion to use adrenalin from different sources either experience remarkable success or complete failure. The active principles of the capsules of different animals, oxen and sheep, for example, all having approximately the same appearance, and having chemical reactions in common, have not the same physiological action." Reviewing this part of the subject M. Noé remarks that it is necessary, to avoid misconceptions, to make use only of products of which one already knows the effects.

The process for the extraction of adrenalin is then considered, and considerable space is devoted to the physical and chemical reactions of the base. Adrenalin is very soluble in acids and forms salts which crystallise with difficulty; the hydrochloride, sulphate, tartrate and benzoate have been prepared, but the first named is preferred on account of its greater solubility in water. With regard to the constitution of adrenalin, M. Noé quotes Jowett, who confirms Aldrich's formula, which also had been adopted by Von Furth and Pauly. The last portion of the paper deals with a colorimetric process for estimating the value of the base, proposed by Battelli; but numerous critics, quoted by M. Noé, are of opinion that the process is very unsatisfactory.

### Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, July 17th, 1904.

At the Free Society of Surgeons, Hr. Braun spoke on

#### POST-OPERATIVE DISTENSION OF THE STOMACH.

He had seen five cases of acute ectasis of the stomach, two of them after extirpation of the vermiform appendix, two after laparotomy for ruptured tubal pregnancy and one after a gall-stone operation. This was

to be looked upon as primary atony of the stomach made worse by absence of vomiting; what was the cause of the reflex nervous phenomenon had not been yet explained. He had made experiments on the subject which were not yet completed, and had observed that one could blow up the stomach of a chloroformed animal through a gastric fistula without exciting vomiting. Vomiting came on more readily when the animal had not been anaesthetised.

The most important was prophylaxis, the mere washing out of the stomach as soon as the first symptom appeared.

Hr. Birchardt reported a case of enormous distension of the stomach after nephropexy. Death took place in a short time.

Hr. Körte had done gastro-enterostomy in a case of distension of the stomach coming on without a previous operation. The stomach remained distended. Death took place from necrosis of the wall of the stomach and peritonitis. The case was one of atony from over-distension.

At the Medical Society Hr. Orth showed

#### A CYSTICERCUS OF THE PIA MATER.

He had been interested to know whether there was any diminution in the frequency of this disease, and for the purpose of ascertaining he had gone through the registers of the Pathological Institute. From these he had learned that cysticercus of the brain had notably diminished since 1875, and especially during the past five years. He had only found one case during this latter period. He also showed an echinococcus situated in a branch of the portal vein, and thus stuck fast on its way from the intestinal canal to the liver. He had made similar inquiries in regard to echinococcus as he had done for cysticercus, and had ascertained that no material change in the frequency of its occurrence had taken place during the last thirty years.

The *Deutsch. med. Zeits.*, No. 53, relates a

#### CASE OF PURULENT PERICARDITIS TREATED SURGICALLY.

The patient was a man, æt. 28, who had been struck on the chest by a beam. After this he had a rigor, and his breath became short. The latter was so bad that the patient had to maintain the sitting position. A phlegmonous swelling was seen on the right side of the chest, and at a spot between the second and third ribs there was fluctuation. The lungs were healthy. In view of the excessive dyspnoea and lowered blood pressure, for the kidneys were scarcely acting at all, pericarditis *per continuationem* was suspected. The following day an incision was made at the level of the third rib, when it was ascertained that there was a large abscess just below the pectoral muscles and necrosis of the rib. As the swelling bulged forward here a scalpel was introduced at the spot, the scalpel entering the pericardium near the great vessels. The cardiac action was at first irregular, but as the abscess cavity drained the pulse became more regular again. About 1½ litre of pus was evacuated. The heart was floating above the abscess. Drains were inserted, but the cavity was not washed out. On the twelfth day the drains were removed; on the fifteenth the patient was allowed to sit up, and on the twenty-first he was discharged. Three months later the cardiac dimensions were about normal, the pulse being 72 to 76 when at rest, but rising to 100 when the patient moved about.

At the Society of Charité Aerzte, Hr. Ziehen showed a case of

#### APHASIA.

The patient was a woman, æt. 60, who had a hole in her bony skull. She was a drunkard and probably

syphilitic. Disturbances of speech came on suddenly. In going on to speak of some advance in our knowledge of aphasia he said there was a sharp distinction between the sphere of acoustic perception and that of acoustic recollection. The latter could be disturbed in a brain in which power of hearing was retained. Perhaps a word was recognised, whilst for understanding it other parts came into consideration. In such cases it was always of interest whether optic receptivity and recollection were retained. In the case before them the tract to the optic sphere was intact. Total loss of both was very rare. Exhaustion also played a certain part. Transference from Broca's centre to that of Werneck was absent. When it took place, the route need not be direct, a circuitous one over the optic centre was always possible. In reading there came into consideration—the visual sense, the reading centre (Naunyn), the sphere for sound images (Klangbilder) (Wernecke), and the object presentation in the visua sphere. The recording centre had been disputed, but the objection was not justifiable. The reading centre, however, presented only the optic recollection of the image of the letters. There was a difference here between educated and ignorant patients. Such disturbances as were present in the case before them were pathological—anatomically perhaps worse than they were from a clinical psychological point of view.

What the disease was was difficult to say: perhaps there was a tumour, perhaps syphilitic changes.

Hr. Seiffer showed

#### TWO CASES OF PERIPHERAL PARALYSIS.

The first patient had influenza, pneumonia, and phlebitis and wasting of the right upper arm, the latter from paralysis of the musculo-cutaneous nerve, from which all the parts supplied by the nerve were affected; only ten to twelve such cases were known. Trauma was generally the cause, but in two it was caused by infection.

The other case was one of paralysis of the deltoid from paralysis of the axillary nerve. It followed an operation on a cervical rib. There was no atrophy and no reaction of degeneration.

## Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, July 17th, 1904.

#### PSEUDO-HERMAPHRODISM.

At the Gesellschaft der Aerzte, Swoboda showed a child, *æt.* 1, with genitals that appeared at the first glance to be female, but a closer observation revealed a more complicated state of affairs in the addition of testicles and præputium arising from the vulva major. The urine was discharged from an opening at the lower part of the penis. Further investigation with sound and digit failed to reveal the sex. There was no justification for opening the gland for microscopic purposes, and hence the case was left undetermined whether the patient was male or female, leaving legislators to provide for a third abnormal sex.

Foges said the diagnosis of these cases was a very difficult task when the patient was so young. Happily, the functions of such glands were inactive, which further added to the difficulty, but he considered operative interference unwise at the present time.

#### TEARING OF THE MESENTERY.

Schnitzler exhibited a child, *æt.* 10, on whom he operated for internal rupture after being run over by a vehicle. On opening the abdomen a large rent was found in the mesentery with invagination of eight centimetres of small intestines, of recent

origin, which, he thought, might be caused by the contused wounding of the bowel producing a spasmodic action and final invagination.

Exner differed from Schnitzler in presuming the invagination to be a simple spasm. He considered it a physiological result due to the loss of co-ordination between the circular and longitudinal muscular fibres of the bowel.

#### ACNEFORM TUBERCULIDES OF THE SKIN.

Arising out of a previous discussion on atrophica cutis idiopathia, Ehrmann brought forward several cases bearing on the subject. The first was one having a variety of phenomena, but all pointing to a tuberculous form of the cutis. The neoplastic growths ranged from the size of a hempseed to that of a pea, having a bluish colour with a necrotic centre; along with these were larger erythematous indurations about the size of beans, having a dark red colour with a cheesy centre.

Alongside of these cases he brought a few of atrophica cutis idiopathia for comparison.

Sternberg said he had made a microscopic examination of the patients with the atrophica cutis idiopathia and found a state of hemosiderosis present.

#### UTERINE CARCINOMATOUS OPERATIONS.

Wertheim next treated the Society to a long history of uterine operations, comparing his own experience with other operators, ancient and modern. The best measure of the success in a uterine operation was the period of immunity after operation. The most successful operators removed the uterus, parametrium and all the glands in the region affected, which can only be done by the laparotomy method. He divided the period of recurrence into three for comparison. He had now fourteen cases over four years since operation, or 29 per cent. The corresponding numbers given by other authors are—Chrobak, 7·2 per cent.; Schauta, 5·1 per cent.; Zweifel, 9·5 per cent.; and Pfannenstrel, 6·8 per cent.

Those recurring between three and four years in his own experience was 27·5 per cent. survived; while Chrobak records 7·4 per cent.; Schauta, 6·6 per cent.; Zweifel, 10 per cent.; and Pfannenstrel 7·1 per cent. Surviving after two years were Wertheim, 31 per cent.; Chrobak, 8·5 per cent.; Schauta 8·6 per cent.; and Zweifel, 11·6 per cent. He thought these results were due to the advantage laparotomy had over vaginal extirpation. Discussion on the subject was reserved for a future meeting.

#### HÆMOLYSIS.

At the Congress für innere Medizin, Koeppé gave the results of his experiments on the solution of red blood corpuscles. The methods adopted in this inquiry go under different names, but the resulting phenomena are much the same. Hæmolysis signifies a previous morbid condition which has hitherto baffled the investigation of the experimenter as to the proximate cause, although the immediate cause is a rapid decline and death of the cell. In examining the immediate causes a series of conditions leading to dissolution may be cited and arranged *seriatim*:—(a) water hæmolysis, (b) caloric hæmolysis, (c) alkali hæmolysis, (d) acid hæmolysis, (e) fatty hæmolysis; and finally the sera, toxin and hæmolysin hæmolysis. The true cause of these changes in the blood cell or hæmolysis is the wounding or solution of continuity of the pellucid wall of the red blood corpuscle. This membrane contains a fatty or lipid constituent with an albuminoid coagulating substance. The water or hydro-hæmolysis is more of a mechanical agent than chemical, as it distends the cell by an internal osmotic pressure. Again mechanical injury is caused by cold or freezing, and thawing of the cell wall as well as by electric shocks

In caloric hæmolysis it seems to be due to a melting of the wall or solution of the fatty constituent. In acid hæmolysis the fatty constituent of the wall undergoes a catalysis in the alcohol formed from the acid, finally splitting up the fatty constituent. In the alkali hæmolysis a saponification in the alcohol with a resulting fatty salt is the final transformation. In all the sera hæmolysis the albuminoid constituent of the cell wall is the element attacked.

## The Operating Theatres.

### ST. MARK'S HOSPITAL.

**ABDOMINAL FIXATION OF THE SIGMOID MESO-COLON TO RECTIFY RECTAL PROLAPSUS.**—Mr. SWINFORD EDWARDS operated on a man, æt. about 60, who was suffering with procidentia recti, which had followed a Badenhauer's excision of the rectum for malignant disease eighteen months previously. The patient had been put to great discomfort owing to the rectum prolapsing some three or four inches from the sacral anus on the slightest exertion, so Mr. Edwards proposed to sling up, as it were, the lower part of the large intestine by means of an iliac incision, supplementing this operation, after the lapse of a week or two, by the repairing of the anus as is carried out for the repair of a ruptured perinæum. The ordinary incision was made in the left iliac region as for an inguinal colotomy, though the incision was placed a little nearer to the middle line and somewhat lower down. The muscles and aponeuroses having been divided in the direction of their fibres, the peritoneum was incised and the abdomen entered. The sigmoid flexure was brought out of the wound and pulled taut at its distal end, the slack being passed back into the abdomen. The tautened meso-sigmoid was now sewn by fine silk sutures to the peritoneum, and to the inner surface of the muscular wall, about half an inch from the lower lip of the incision, and the abdominal wound closed in layers. Mr. Edwards said that he should not rely entirely on this operation to cure the procidentia, although, no doubt, it would help in doing so; but he proposed, if all went well, to lessen the size of the sacral anus and thus bring two forces to bear for the relief of the prolapsed gut, the one being on the principle of *vis à fronte* and the other on the principle of *vis à tergo*. He remarked that he had carried out a somewhat similar operation some little time previously in which he had endeavoured to fix the rectum in a case of procidentia recti to the tissues about the coccyx, but as this was not attended with any success he had discarded it in favour of iliac fixation, of which he had had two successful cases.

The patient a fortnight after operation had shown no trace of any prolapse, but then he was still confined to his bed, and Mr. Edwards proposes to do the second part of the operation, namely, tightening up the anus, immediately.

### CANCER HOSPITAL.

**GASTRO-ENTEROSTOMY FIFTEEN MONTHS AFTER PYLOROPLASTY.**—Mr. BOWREMAN JESSETT operated on a woman, æt. 46, who had, in January, 1903, been admitted for symptoms lasting then for some two years—constant vomiting, nothing being retained on the stomach, and the woman was losing flesh rapidly. The weight at the time of the first pyloroplasty in January, 1903, was seven stones. At this operation, on opening

the stomach the pylorus was found tightly strictured; an old ulcer, partly cicatrised, was seen at the posterior edge of the pylorus. Mr. Jessett divided the pylorus longitudinally for about three inches, and then sutured the surfaces together laterally, first of all suturing the mucous membrane with catgut, and then the serous and muscular coats with fine silk. The patient made an excellent recovery, and was discharged about three weeks after the operation. She remained well for some nine months, after which the old symptoms began to return, but in November of the same year she had picked up four stones in weight, then weighing eleven stones. Since then, she had been gradually losing flesh again, and at Christmas vomited up about one and a half pint of dark fluid. In March, 1904, she was again admitted into the hospital, her weight then being nine stones, she having therefore lost two stones in the four months. When re-admitted she was in fairly good health, but complained of a good deal of pain after food, most of which she vomited shortly after taking it. Mr. Jessett then performed gastro-enterostomy. He opened the abdomen along the left line, the incision commencing about an inch and a half below the costal cartilages, and extending downwards about three inches. The stomach was drawn out and a loop of jejunum also hooked up. He then proceeded to fasten the jejunum to the anterior wall of the stomach, close to its greater curvature. He at first applied a continuous fine silk suture, passing through the serous and muscular coats of the stomach and the jejunum, enclosing in a circular form a space some three inches long by two wide, leaving the ends long and ceasing about two inches from the completion of the oval. He next incised the stomach transversely for two inches, and the jejunum longitudinally for the same distance, and, with a continuous suture, stitched together the cut surfaces of the stomach and jejunum, completing the junction and thus ensuring a free opening between the two viscera. He then with the first suture continued the fastening of the serous and muscular coats. Mr. Jessett next introduced a few stitches through the serous and muscular coats of the proximal end of the jejunum, fastening it to the stomach wall to prevent any kinking; finally, he brought together the parietal wound in four layers, *i.e.*, three layers of buried suture and one for the skin. Mr. Jessett said that he thought this case illustrated very well the effects of gastro-enterostomy as against pyloroplasty. He pointed out that it has often been a question how far the pylorus, after being stretched by Loreto's operation or divided and enlarged by pyloroplasty, may become contracted again; the present case, he thought, illustrated that in every instance of pyloric obstruction it would be wiser to at once perform gastro-enterostomy in preference to interfering with the pylorus. Mr. Jessett also drew attention to the method he had adopted in performing the gastro-enterostomy; he used no bobbins or Murphy's buttons, but simply fastened the jejunum to the stomach by two circular continuous sutures, one passing through the serous and muscular coats and the other fastening the cut edges of the stomach to those of the jejunum. He was of opinion that with few exceptions any short circuiting of the intestines or intestinal anastomoses might be performed perfectly safely and nearly as quickly by the means he had employed as by bobbins, plates, or buttons.

The patient left the hospital a month after operation, and is now in the enjoyment of fairly good health; the vomiting has entirely ceased and she has gained weight.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, JULY 20, 1904.

**SIGHT-TESTING BY SPECTACLE-MAKERS.**

THE Ophthalmological Society of the United Kingdom, albeit somewhat late in the day, has made a definite public announcement with regard to the proposed inclusion of sight-testing in the examination subjects for the diploma of the Worshipful Company of Spectacle-Makers. It has issued a report, signed by Mr. John Tweedy, the President, stating briefly the grounds of objection to the proposal in question. The first issue raised is the misleading value of such a diploma, which would induce the public to believe its owner to be competent to diagnose and to treat diseases of the eye. There is no need to point out to medical readers the disastrous consequences that must infallibly dog the footsteps of the unqualified dabbler in ophthalmic work. There is no branch of the medical art that demands greater experience and technical skill than that of ophthalmology. The recognition of the exact nature of the earlier stages of many such affections demands the instant application of various highly specialised methods of scientific investigation. It is precisely in such early cases that a sufferer would be likely to go to an optician, who, armed with just enough knowledge to be dangerous, would waste the precious moments in which the sight might yet be saved by the skilful promptitude of a trained ophthalmic surgeon. The mechanic, for that is the position of the optician when he is not a tradesman pure and simple, cannot be expected to recognise the signs, symptoms and purport of corneal ulcer, opacities of the various media, iritis, gonorrhoeal and other conjunctivitis, detached retina, and glaucoma, to mention a few only of the many urgent conditions that would infallibly come sooner or later under his notice. The thin end of the wedge of the Spectacle-Makers' Company has indeed led to a serious chasm—one that is fraught with danger to the public and

with injustice to the medical profession. As pointed out in the report, errors of refraction often occur in association with diseases of the eye. The mere correction of the former by means of spectacles would ignore a condition which might destroy sight, or even leave the life of the patient in danger. Considerations of that kind, however, are not wont to stay the hand of the amateur in medical matters. The resulting toll of suffering, disease and death paid annually by the inhabitants of the United Kingdom must be something appalling. The efforts of the constitutional law, on the one hand, to protect the people by insisting on proper qualification for medical practitioners is outweighed on the other by the almost absolute licence given to unqualified practitioners and patent medicine vendors. The report properly points out that on general grounds it is dangerous to encourage the public in the belief that affections of any organ of the body can be safely treated by anyone unacquainted with its anatomy and physiology, and with the various morbid conditions to which it is liable. It is to be hoped that the widest publicity will be given to this document. The public need education in the matter, not only of their eyes, but of the rest of their bodies, by the comparison of qualified medical practice with that of quacks. The encroachment of the Spectacle-Makers is but a specimen of what has gone on in a thousand other directions. Any sort of labourer or tradesman may, like the spectacle-maker or vendor, imagine he has the divine gift of healing. The road from the workshop or the tradesman's counter to the consultation room is easy, and the rewards lucrative. Nor is it possible to forget that a medical man has only recently resigned the position of examiner for the diploma issued by the Spectacle-Makers' Company. That gentleman was a member of the Ophthalmological Society, a body that could have put an end to such an anomalous position long since. Had the Society faced that matter squarely and fairly, as it should have done, years ago, their task of convincing the public would not have been so hard as they will find it to-day, when the unpleasant fact of that examinership is thrown in its teeth. The battle of the Ophthalmological Society, however, is that of the medical profession, and, as such, deserves the hearty support of every medical man in the United Kingdom.

**GAS POISONING.**

DURING the past few years members of the medical profession in Dublin have, from time to time, drawn attention to the danger to public health which results from a change in the nature of the gas supplied to the public for illuminant and cooking purposes by the gas company of that city. Up to 1900 the gas supplied was normal coal gas containing the normal 6 per cent. of carbon monoxide, but in February of that year the company altered the nature of the gas by adding a considerable quantity of carburetted water gas. Water gas is made by passing steam over red hot

coke, and is then carburetted by being charged with vapour of petroleum or other inflammable oil. It possesses advantages over coal gas in that it is cheaper and more easily produced to meet an emergency, while, especially when mixed with coal gas, it makes an excellent illuminant. It possesses, however, one very serious disadvantage-- *it contains 30 per cent. of carbon monoxide.* Very shortly after it was introduced by the Dublin gas company, without, be it said, any warning to consumers, Dr. Emerson Reynolds, then Professor of Chemistry in Trinity College, drew public attention to the dangers which might result. He pointed out that in case of accidental leakage of gas, through untrustworthy fittings or otherwise, the danger to life was far greater than when coal gas alone was used. His prediction has been amply verified, for we find that during the past four years no less than ten cases of gas poisoning have occurred in Dublin, with seven fatalities, while in the previous twenty years no case was recorded. Dr. McWeeney has collected particulars of the several cases, and published (a) them in a manner which should focus public attention on a serious danger. In all the cases poisoning followed on an accidental leakage of gas, though in some of them the cause of the leak was difficult to trace. In the first occurrence, for instance, gas was not laid on at all in the premises where the poisoning occurred, but the main in the street outside became broken, and the gas filtered through the soil into the house. Four persons suffered, with one death. In another instance a whole family was sacrificed in a clumsy attempt to defraud the gas company by short-circuiting the meter, and in another an elderly couple from the country, while staying in a city hotel, probably poisoned themselves by blowing out instead of turning off the gas. Again, a young man, apothecary in one of the city dispensaries, was asphyxiated in his bath-room owing to the use of a "geyser," which was probably insufficiently lighted. At present the gas in Dublin contains 16 per cent. of carbon monoxide; up to 1900 it only contained 6 per cent. As small a quantity as .2 per cent. of carbon monoxide in the air is dangerous, and with increased quantities Haldane has shown that the mortality increases as the cube of the increase in the proportion of monoxide. His investigations were made in Boston and Chicago, where the introduction of water gas has been followed by similar results to those that have occurred in Dublin. At present, however, in these countries the public is at the mercy of the gas manufacturers. The sanitary authority in Dublin, which has been appealed to, professes itself powerless to interfere to limit the proportion of carbon monoxide supplied in illuminant gas. If this is so there is urgent need for legislation, but in the meantime we believe the sanitary authority has power to insist that all fittings and gas-cooking apparatus shall be kept in proper order, and that gas mains shall be laid in the street with due care against accidental breakage.

(a) *Dub. Journ. of Med. Sci.*, July, 1904.

#### CENTRAL MIDWIVES' BOARD AGAIN.

THE doings of the Central Midwives' Board since it came into being have been such as to thoroughly justify all that was formerly predicted of the scheme to give midwives official recognition. We lately called attention to some of the ill-judged and over-bearing actions that it has already perpetuated, and showed how those actions were judged by the medical profession. At the last meeting of the Board a motion was brought forward by Dr. Cullingworth that a list of examiners under the Act should be prepared by the Board from those who were willing to serve when required. Dr. Ward Cousins moved a very proper amendment to the effect that no one but a registered medical practitioner should be appointed as an examiner. This amendment, which would have appeared superfluous in the ordinary way, so obviously necessary is it that the examiners should be medical men, was supported by Mr. Parker Young and Dr. Sinclair, but after some debate it was defeated by the votes of Dr. Cullingworth and the three female members of the Committee. This action, we venture to think, for sheer stupidity and offensive disregard of medical opinion, fittingly caps the egregious performances of the Board up to the present time. It is a deliberate and direct slight to the profession of medicine, and it cannot be too strongly resented by those who hold its dignity dear. Medical men have all along been opposed to the creation of a sub-order of practitioners on an independent footing, and it was only out of regard to the welfare of the poor—the question resolving itself into whether they should be attended by trained or untrained midwives—that they abated their opposition, conditionally on the training of these women being left in their hands. The Central Midwives' Board was constituted, and it has persistently endeavoured to show a disregard to all that is deemed essential by medical opinion. But there are limits to this policy, and it seems not unlikely that those limits will soon be reached unless the Board decides to mend its ways. However much it may wish to the contrary, it is only by and with the co-operation of the profession that the Act can be made to work, and if it continues to snub and override the profession it will find that its work may come to a standstill by medical men giving it the cold-shoulder. In the present instance the deliberate opinion of the majority of the Board is that it may be not only possible, but even advantageous, to appoint a midwife to sit side by side with medical men to examine candidates for admission to the register, candidates, be it remembered, who have been trained by medical men. In other words, the Board approve of the principle that a person who has had three months' "training" in midwifery shall sit in judgment on the work of qualified practitioners, and sees nothing incongruous in a professional man acting in subordination to the criticisms of such a person. The medical profession will think otherwise, and, if we mistake not, will show

its aversion in a very practical manner. The specious plea was advanced that a midwife or matron would know about nursing what a medical man would not. Whence, we wonder, have the nursing profession of the day obtained this knowledge in training except from the hands of medical men? The pretext is too flimsy to deserve serious consideration. Nursing is essentially and ultimately a medical question, and the trained nurse is taught, and generally recognises, that she is not an independent professional expert, but an assistant and subordinate to the qualified practitioner. No good nurse wishes to be anything else; she learns enough during her probation to know her own limitations. It is not so with the midwife and those who wish to push her and her practice. The midwife is to act in cases surrounded and attended with anxiety and danger on her own initiative and responsibility, and when she finds things are getting too much for her, to send for a medical man. The exaltation of the midwife and the degradation of the medical man is tacitly the underlying aim of a number of philanthropically-minded people who have interested themselves in the question, and it is an aim which is being fostered and forwarded by the action of the Central Midwives' Board. The doctor is to be ignored as long as possible, and called in—without any provision being made for his payment—when the midwife scents trouble ahead. That is the line taken by the Midwives Act, and the spirit of the Midwives' Board perpetuates the evil tradition. Let the doctors do the training, and the midwives, when they have had the benefit of it, help with the examining and see if the doctors are doing their work properly, forsooth. It is difficult to conceive how a medical man of Dr. Cullingworth's eminence can be found to acquiesce even passively in such a proposition, and we can assure him that Dr. Ward Cousins spoke no more than the truth when he said that he was convinced that the medical profession felt very strongly on the point. If the dangers to the poor entailed by the Act are to be obviated, it is only by leaving the whole question of preparing midwives for their work entirely in medical hands, and enforcing on them that the safety of the mothers and children whom they attend can be attained only by their recognising the vast inferiority of their knowledge to that of the practitioner. Such an end is not likely to be attained by putting midwives to sit cheek by jowl with medical men on examining boards. Dr. Cullingworth has incurred a great responsibility by deliberately voting for the subordination of qualified medical men to mere midwives, and, if we mistake not, he will have sooner or later to be called upon to render an account of his stewardship to the medical profession, to which he owes his position.

### Notes on Current Topics.

#### Beri-Beri as an Epidemic.

IN view of the serious outbreak of beri-beri

among the Chinese labourers in South Africa, our contemporary *Truth* does a public service in recalling the mismanagement shown by the Irish Executive during the epidemic which occurred in the Richmond Asylum, in Dublin, some years ago. The first cases occurred in 1894, and during that year no less than 174 cases appeared, with twenty-five deaths. The disease then apparently disappeared, but recurred in 1896, and in that year, and during the first half of 1897, over 200 cases occurred. From the first the medical staff pointed out to the authorities at Dublin Castle the impossibility of coping with the outbreak while the asylum was as scandalously overcrowded as it was at that time. Of this overcrowding it is difficult to convey an idea, but in most of the dormitories there was barely standing room between the beds, and many of the corridors had to be converted into dormitories by placing a continuous row of beds along the walls. In spite of the continual protests of the medical staff, the Press, and the public, it was not till August, 1897, that accommodation elsewhere was provided for some of the surplusage of patients. We trust that the Transvaal authorities will take to heart the lesson taught in Ireland, though, up to the present, the official telegrams appear of an unwarrantedly complacent nature, and hardly show a due sense of the seriousness of the situation.

#### Spontaneous Rupture in Ascites.

Nor the least complex among the problems of pathology is the mechanism of the production of those peritoneal exudations which, accumulated in any quantity, give rise to the condition known as ascites. The integrity of the portal circulation and the phenomenon of osmosis, in addition to being interdependent, are themselves influenced by other factors about which our knowledge cannot yet be said to be complete. The removal of ascitic fluid by mechanical means is a frequent operation, and the immense relief afforded by a timely paracentesis to a labouring heart is a constant source of satisfaction to the physician. Too often, though, the abdomen fills up again rapidly, necessitating repeated tapplings. In a few instances a gradual absorption of the fluid undoubtedly occurs, especially under the influence of a restricted diet and the application of graduated abdominal pressure. Spontaneous rupture of the abdomen with escape of the peritoneal exudation is an accident which is so rare that the case recently reported by M. A. Cochez (*a*) before the Société Médicale des Hopitaux is worthy of note. The patient was a man of fifty-two, who twenty years ago had contracted malarial fever. The liver then became enlarged. After his recovery he developed alcoholic habits, and three years ago ascites appeared, the liver being cirrhotic. He was tapped frequently, and after the forty-eighth puncture a small vegetation appeared just below the umbilicus. This gave way to a minute patch of ulceration, looking more like

(a) *Bull. et Mem. de la Soc. Med. des Hop.*, Paris, June 23rd, 1904.

granulation tissue. A month afterwards he was again tapped, and a week after this, the forty-ninth paracentesis, ascitic fluid was suddenly ejected through an aperture in the centre of the ulceration during a violent fit of coughing. The abdomen emptied itself completely, and a doctor who was hurriedly summoned closed the opening with collodion. The accident was regarded as a departure from the normal process of peritoneal cicatrisation, which was evidently in progress. M. Cochez considered such a contingency favourable rather than otherwise, as indicating an attempt of Nature towards a spontaneous cure. In the few cases of accidental rupture recorded in the literature, the perforation has nearly always been preceded by a gangrenous ulceration of the abdominal wall, not necessarily connected with the scars produced by puncture.

#### Responsibilities of Nursing Associations.

AN appeal case of considerable importance with regard to the legal responsibilities of nursing associations was decided last week in the London Law Courts. The Oldham Nursing Association sent a nurse to attend at an operation. By her negligence a hot-water bottle was allowed to lie in contact with the bare skin of her patient, who was burnt thereby, and who brought an action for damages. Plaintiff was awarded £300 damages by a jury at Manchester assizes. Defendants appealed on the ground that they were not in point of law liable for the acts of their nurses, who were, they contended, at the time of the alleged negligence, the servants of the lady they were attending. The Master of the Rolls granted the appeal, finding the Association was not liable for any want of ordinary care and skill on the part of the nurse they supplied. For the purposes of nursing the nurse thus sent was in no sense the servant of the Association, which, therefore, was not liable for her carelessness. Medical men should note this judgment. A special contract with the nursing home would tie down a nursing association to a proper responsibility for its nurses.

#### The Doctor in the School.

THE favourable reception which the petition in favour of the teaching of hygiene in schools met with at the Education Office is, in itself, an evidence that the urgent need of such instruction is at least recognised by the Government. The medical profession as a whole was fully represented by the large number of signatories, and such a petition could hardly fail to carry weight with those in authority. But it is not only by the teaching of hygiene and allied subjects by men and women who have been through certain courses of instruction themselves that we can hope to stay the tide of physical degeneration which threatens to submerge the coming race. The need for a qualified medical practitioner to be definitely attached to a school or group of schools has been urged before in the columns of THE MEDICAL PRESS AND CIRCULAR. In connection with this point attention may be

drawn to the most instructive report recently prepared on the Public Schools of Berlin and Charlottenburg by Mr. George Andrew for the Scottish Education Department. In these cities the fact has been recognised that the elementary school is incomplete without the services of a medical man. Wiesbaden was the first place in which the idea was adopted, and in 1901 ten doctors were appointed for this purpose in Berlin. Our own countrymen might well learn some valuable lessons from the newer schools in Charlottenburg, where the school doctor has his own room in the school buildings in which weighing-machines, and instruments for testing vision, &c., are kept. Periodical examinations of each scholar are made from the medical point of view, the parents being present at the first of these; records are taken and kept of the child's physical condition, and appropriate suggestions are made by the medical officer in charge as to diet and school treatment in general. A weekly bath is also given to each scholar, with the exception of the two youngest classes—a most excellent plan, well worthy of imitation. It is sincerely to be hoped that some such system as this will ultimately find its place in every Council school in this country.

#### Ocular Gymnastics.

THE avidity with which medical, or more generally pseudo-medical, details are devoured by the public is one of the characteristic features of the present age. No matter whether bone-setting, pain-killing, or beauty-restoring be the theme, whether it be possible or impossible, plausible or ridiculous, such subjects never fail to attract hosts of the superficial readers and thinkers of to-day. The marvel is that the editors of our newspapers and periodicals admit such articles to their columns. No space would be granted to descriptions of irregular methods of legal practice, for instance; why, then, are accounts of quackery and specious "cures" tolerated? One of the latest of these extravagances is a method for "restoring" sight without the aid of glasses; nay, further, for the painless and expeditious relief of actual cataract without operation. It is well known that the instillation of atropine into the eye will produce considerable improvement in vision in certain cases of cataract, but, of course, this is only temporary. The celebrated "Professor" of the new method does not, apparently, employ even this drug. He contents himself by applying pressure to the globe by means of a special apparatus, which has to be worn at frequent intervals. The explanation of such treatment is said to consist in reducing permanently the antero-posterior diameter of the globe. We are also informed that the blood is the organ of sight, a statement which is indirectly true, but it is difficult to comprehend how an atrophic optic nerve could be made to transmit visual sensations, however greatly increased its vascular supply might become. Massage of the globe is also performed, we presume with a similar

object in view. These gymnastics and "series of pressures" might be fraught with alarming results in conditions, for example, of acute glaucoma. It is a pity that M. De Dion did not confine his attention entirely to his electrical apparatus, in which branch of science he has met with acknowledged success.

#### **Tubercle Bacilli in the Breath.**

IT has generally been held and taught that pulmonary tuberculosis is infectious only through the medium of sputa, and that persons may live in close contact with tuberculous patients without undergoing any risk of infection, so long as they are not exposed to contamination with the sufferers' expectoration. But, like most of the cherished beliefs in medicine, this has been called severely in question, and Dr. Koelzer (*a*) has recently been taking steps to find out if it is not possible that bacilli are exhaled during quiet respiration. His method was to take patients suffering from active tuberculosis of the lung and get them to hold open Petrie dishes before their mouths for varying periods, without coughing or sneezing. He then placed covers on the dishes and examined them by culture and inoculation. Out of fifteen patients so tested he found tubercle bacilli in one dish only, and in that case the patient was suffering from advanced disease with laryngeal ulceration. There is an obvious fallacy about the single Petrie dish. Though one swallow does not make a summer, the result is nevertheless sufficient to make one consider whether Dr. Koelzer's conclusions may not possibly be justified. In his opinion it is possible that during quiet breathing tubercle bacilli may be freed from the muco-pus in the finer tubes by the bursting of the small bubbles produced by air passing through them—those bubbles that one hears as crepitations. The bacilli thus freed may be carried out in the expiratory current, just as they were originally carried in by the inspiratory current. On the other hand, the number disengaged and exhaled in this manner are very few, and probably are not factors of much practical importance in the spread of the disease, but in cases of laryngeal ulceration the numbers are likely to be considerably larger than in cases when the lung only is affected. It seems within the bounds of possibility that Dr. Koelzer is right; at any rate, this side of the question should always be borne in mind in cases where the patient is a husband or wife, and is often in close contact with a healthy person for many hours. It should certainly impress on medical men the duty of insisting that a tuberculous patient should sleep in a room by himself.

#### **The L.G.B. and Tramps.**

THE announcement that the President of the Local Government Board has appointed a Departmental Committee to investigate the subject of vagrancy will be received with great satisfaction by readers of THE MEDICAL PRESS AND CIRCULAR.

(*a*) *Zeits. f. Hyg. u. Infekt. Krank.* Vol. xlv, p. 2.

and by sanitarians generally. Time and again the serious medical aspects of the system by which tramps are allowed to roam the country at their own sweet will have been pointed out in our columns. These "sturdy beggars," as our Elizabethan ancestors would have called them, have been shown to be most potent agents for disseminating small-pox, and there is every probability that variola is only one of the pests for which they are responsible. From the economic point of view, the tramp is not only a disgrace to the community, but he exerts an evil influence on the labouring classes, and without unduly infringing the liberty of the subject it should be quite possible to restrict his activity to a considerable extent. From the medical point of view he should undoubtedly be subjected to the most rigorous supervision and regulation. Dr. Armstrong, of Newcastle-on-Tyne, has been advocating this for the last ten years, showing that more than half the outbreaks of small-pox are originated by the unwelcome presence and habits of tramps, and various authorities have been trying to get the Local Government Board to take the matter in hand. Everything comes to those who wait, and one must not be ungrateful now that this tardy inquiry has been set on foot. It would have been more reassuring had the Committee contained more than one medical man, but here again we must be thankful that Dr. Downes, with his wide experience of Poor-law administration, has been chosen. Let us hope that the inquiry will be thorough and the recommendations unhesitating, for the able-bodied loafer deserves little sympathy, and he has no right to constitute himself a standing menace to the health of useful and industrious people. At the same time, it is impossible to forget that the tramp is a product of society, and that his legal rights to maintenance have been recognised by the law of the land.

#### **Medical Men and Drink Legislation.**

THE drink question has recently been laid before the public in all its various bearings by the licensing proposals of Mr. Balfour's Government. There can be hardly any one great social question on which the medical profession is better qualified to speak with the voice of authority. The National Church has spoken with a somewhat wavering voice upon the matter, but on the whole its support of temperance interests has been emphatic. Why should not medical men speak out their collective mind as to whether Mr. Balfour's alterations in licensing law are likely to increase the facilities for drinking amongst our countrymen or the reverse? The fact that alcohol lies at the bottom of a vast mass of disease, crime, misery, and avoidable suffering amongst mankind is brought home daily, nay, hourly, to the medical man. Why should he not proclaim his opinion without regard to politics or creed, to brewers or any other class upon a point that touches more or less nearly the happiness of every man, woman, or child in the United

Kingdom? That the medical profession is able to take such a step was shown by the petition signed by 17,000 medical men and presented to the Education Department with a view of rendering the teaching of hygiene compulsory in State schools. There is little use, however, in allowing our labouring classes to sap their manhood and bequeath a broken constitution to their offspring, and then to trust to school lessons to mend matters. Regulate the parents' drink first, and teach the children afterwards. Begin at the foundation.

#### Caisson Disease.

EVER since it has been the custom to dig in the bowels of the earth in atmospheres of high pressure, something has been known of the condition which at present goes under the name of "caisson disease." The symptoms, which come on after the release from the high pressure chamber, are various, and, at first sight, quite disconnected. One of the commonest is a colicky pain which has given the disease its nickname of the "bends" among American workmen. Sometimes the joints swell, and there may be a violent pruritus, known in the vernacular as "fleas." Sharp muscular pains are common, and more serious symptoms are stupor, anæsthesia, coma, deafness, blindness, sudden death. It has been noticed that the symptoms do not occur if the period of decompression be gradual and prolonged, and with this precaution very high pressures can be borne without injury. The only treatment which has ever been effective is an immediate return to a high pressure, followed by very gradual decompression. The pathology of the condition was for long ascribed to minute hæmorrhages occurring in the spinal cord and elsewhere, but this view is now abandoned. The researches of Hoppe-Seyler, Paul Bert, and others showed that the true cause was the sudden return of the gas dissolved in the blood and tissues to the free state, owing to the sudden relief of tension. During the period of pressure, the blood, like the fluid in a closed soda-water bottle, contains large quantities of gas in solution; on the pressure being diminished, ebullition occurs, just as when the cork is drawn from the bottle. The chief gas concerned is nitrogen, for the absorption of oxygen is but little altered by atmospheric pressure, and that of carbon dioxide not at all. The frequency of the disease during engineering operations in America is becoming somewhat of a scandal, and as it can absolutely be avoided by reasonable care, it is time that the authorities should step in and insist on the necessary precautions being taken.

#### A Faith Cure by Fire.

A DRAMATIC episode was given last week by the *Daily Chronicle*, of a cripple who suddenly recovered the use of his limbs. The account relates to one Pat Shay, who for four years had suffered from paralysis of the legs, which compelled him to walk about on crutches. One night he saw fire issuing from a shop in Seven Dials, London. With the help of another man

he burst open the door, and then, flinging away his crutches, he dashed upstairs and brought down a baby. The two men between them rescued the rest of the inmates. This case appears to the *Chronicle* writer, as it would to the ordinary man in the street, in the light of a miracle. If the paralysis were muscular, due to peripheral neuritis, there is nothing surprising in the recovery. The "cripple" had most likely been using crutches for some time when he might have walked. Suppose this man Shay had been under the notorious "miner" surgeon or other unqualified person, the full credit of the "cure" would have been acquired in a case where cure was not needed. In a great proportion of instances it is from sufferers of this type that bone-setters and quacks gain their successes. Obviously the man Shay was perfectly honest in the belief that he was unable to walk until the fire showed him the contrary. The crippled British public, however, are not likely to resort to fires to test the reality of their disablement, although, from the point of view of the medical profession, they act little less foolishly in trusting to cancer-curers, faith-healers, unqualified electricians, bone-setters, herbalists, and the rest of the harpies that batten on the life blood of their credulous victims.

#### Formalin in Milk.

THE medical superintendents of the Poor-law infirmaries have been acquainted for some years past with a form of skin disease that occurs in epidemic form at irregular intervals. Savill was the first to describe such an outbreak, and on each occasion there has been reason to suspect milk as the causative agent. Last September one of these epidemics attacked the inmates of the Central London Sick Asylum at Hendon, and Dr. Monckton Copeman was sent by the Local Government Board to investigate and report. The recently published account of his inquiry shows that sixty-eight persons were attacked and that two died, and although this is a lower mortality than usual, it is sufficiently serious. Acting on the supposition that the milk supply was at fault, the patients were all put upon Swiss milk, and from that date they all began to recover. Attention was attracted to the fact that the original milk remained sweet for a long time, and this observation led to a search for preservatives in it, a search that revealed the presence of formalin. In the absence of any well-established action of formalin on the skin it cannot be demonstrably proved that this antiseptic was the etiological factor, but there being no other likely cause, the probability of formalin, or some product of delayed fermentation through its action on the milk being at the bottom of the trouble cannot be lightly disregarded. The subject deserves the earnest attention of sanitarians. The policy of putting preservatives in milk is a vicious one, and the difficulty of securing convictions against those who do so is

great, for the defendants in an action can nearly always call expert evidence to show that nothing certain is known on the subject. If it could be established that formalin has the power of setting up a condition of the kind that occurred at Hendon, the strongest measures would be justified with a view to putting down the unwholesome practice. During the present hot weather formalin solution is doubtless being drunk by the gallon by men, women, and—worse still—by children, and with Hendon's experience before our eyes, we cannot regard the prospect with equanimity.

#### Exit the Slate.

THE slate, with all its associations and traditions, is doomed, and in the course of a generation or so it will be as extinct as the dodo. The light of hygienic truth is slowly filtering through the red-tape barriers of the Board of Education, and for such fitful gleams as gain access to the recesses of its pigeon-holes we must be duly thankful. The facts that slates form a convenient medium for the transfer of pathological organisms from one child to another, and that the licking of slates, affording as it does the easiest and most ready method of deleting mistakes, is a dirty and insanitary habit, have often been pointed out. But custom is hard to break with, and no one in authority has yet had sufficient initiative to attempt to replace the old-fashioned slate by the obviously more convenient and cleanly substitutes—paper and pencils. Perhaps the future school-boy, with his smiling morning face, will go even more unwillingly to school when he knows that he will be deprived of the amusement of drawing portraits of his master that can be crased with a dab of saliva should the dominie's eye travel in his direction, but it is likely that his absences from school will not be so frequent when this hoary institution is relegated to the limbo of things forgotten. Lord Londonderry has not shown himself a brave or vigorous administrator since he went to the Board of Education, and there is plenty of room for well-directed zeal in his present post, but this little reform will serve to show that he is not altogether without imagination. We wish he could have given a more decided and encouraging answer to the medical deputation that waited on him last week to urge that elementary hygiene should form part of the ordinary school curriculum, but in the meantime we must take the abolition of the slate as a hostage for good intentions for the future.

#### PERSONAL.

ON July 15th, his Majesty the King visited Newmarket Workhouse, and after inspecting the hospital wards, made the following entry in the visitors' book: "It is nine years since I visited this union, and I find it vastly improved and in excellent order."

It is announced that Princess Victoria of Schleswig-Holstein, the eldest daughter of Prince and Princess

Christian, has been operated upon for appendicitis at the Prince Victoria Memorial Home, Windsor. The accounts of the progress of the Royal patient are satisfactory.

DR. WILLIAM MURRELL has been appointed Examiner in Materia Medica in the University of Glasgow.

M. A. CHAUVEAU has succeeded the late distinguished physiologist Professor Marey in the Directorship of the Institut Marey.

HIS MAJESTY has approved the appointment of Sir William MacGregor, M.D., K.C.M.G., C.B., at present Governor of Lagos, to be Governor and Commander-in-Chief of Newfoundland, in succession to Sir Cavendish Boyle, who has been appointed Governor of Mauritius.

At a quarterly meeting of the Council of the Royal College of Surgeons of England, Mr. John Tweedy was re-elected President for the ensuing year, and Mr. A. W. Mayo Robson and Mr. Henry T. Butlin were elected Vice-Presidents.

THE President of the Local Government Board, after consultation with the Home Secretary, has appointed a Departmental Committee on Vagrancy, consisting of the Right Honourable J. L. Wharton, M.P. (Chairman), Sir William Chance, Mr. J. S. Davy, C.B., Dr. Downes, Captain Eardley-Wilmot, Captain Showers, and Mr. H. B. Simpson, with Mr. F. L. Turner, of the Local Government Board, as Secretary.

ON the 14th instant, Mr. Sydney Stephenson presided over a large and distinguished gathering at the Hotel Cecil on the occasion of the annual dinner of the Society for the Study of Disease in Children.

MR. JOHN TWEEDY, President of the English Royal College of Surgeons, has revived the annual dinner of the Fellows of that body, and presided at the first dinner held on the July 7th, under the new arrangement in the Library of the College.

It has been proposed by the Berlin Committee for Cancer Research to found a special department in the new buildings of the Charité for the study of that malady under the direction of Professor von Leyden.

DR. E. MODDER, Assistant Colonial Surgeon, Ratnapura, Ceylon, goes to Kalutara in place of Dr. Spittal, who is now medical officer of Colombo.

PROFESSOR VON ESMARCH, of Kiel, has just met with a serious accident by falling out of bed and breaking his collar-bone. In spite of his advanced age his condition is said to be satisfactory.

THE list of the Honorary Medical Staff of King Edward VII.'s Hospital for Officers has been gazetted, the appointments being for five years from January 1st, 1904. Consulting Surgeons, Sir Thomas Smith, Bt., K.C.V.O., F.R.C.S.; Sir Frederick Treves, Bt., K.C.V.O., C.B., F.R.C.S., and a staff of twenty-five other well-known physicians and surgeons.

### Special Correspondence.

[FROM OUR OWN CORRESPONDENTS.]  
SCOTLAND.

SLANDER ACTION AGAINST SIR PATRICK HERON WATSON.—Judgment was given on the adjustment of the issues of this trial on the 12th inst., and notice of appeal has been lodged. Mrs. Jones or McEwan sues for two sums of £2,500, and Mr. Jones, her father, for £2,500. The issues proposed by the pursuers were to the following effect:—(1) Whether in October, 1901, the pursuer employed the defender as her confidential medical adviser to advise her as to her state of health, and in the matter of an action for judicial separation about to be instituted by the pursuer against her husband, and whether the defender, in breach of his

confidential employment in October, 1903, disclosed to pursuer's husband, his law agent, and the counsel engaged on his behalf to defend the action for separation, matters relative to the pursuer's health ascertained in the course of the said confidential employment. (2) Whether at the trial of the separation case the defender, in breach of his confidential employment, voluntarily gave evidence on behalf of Mr. McEwan, and disclosed matters relative to the pursuer's health, to her detriment. (3) Whether in October, 1903, the defender falsely and calumniously stated to Mr. McEwan, his agents, and his counsel that in October, 1901, the pursuer was bent on inducing premature labour so as to free her of any permanent reminder of his marriage. (4) Whether in October, 1903, defender voluntarily made a similar statement in open court in her evidence as a witness on behalf of Mr. McEwan. For the defence counsel contended that as regards the first issue, the alleged breach of confidence, being a disclosure in the course of precognition was privileged equally with testimony given in the witness-box. The whole case turned on the question of privilege, and absolute privilege with regard to a witness' statements in the box was in the interests of the public. If defender was entitled and bound to give the evidence he did in the witness-box, and was absolutely privileged, he could not be held liable for the relative precognitions. Moreover, the pursuer was not entitled to divide the wrong from which she said she had suffered into two parts and claim damages for each—for the alleged slander and the alleged breach of confidence. There was no allegation that the notes which the defender produced at the trial were other than genuine notes of his impressions two years previously, and how a gentleman producing such notes could be accused of acting maliciously counsel could not understand. In any case, even if his lordship should allow of issues, he asked that the case should be tried without a jury. For the pursuer, Counsel stated that the defender was not only in the position of an ordinary confidential medical adviser, but was confidential adviser in regard to a proposed litigation. It was common ground between the parties that Dr. Watson's opinion after he had examined the pursuer was adverse to her, that he was not asked to give evidence on her behalf, that pursuer's agents got intimation that the defender was to examine her on behalf of her husband and as a proposed witness for him in the action for separation, and that the pursuer's agent had brought pointedly before Dr. Watson, before he made his second examination of Mrs. McEwan, that he had previously been employed by her confidentially in connection with that very action. It was also common ground that the defender disclosed to Mr. McEwan not only results of his second examination, but the results of the first, including the contents of the notes. As to precognition being privileged, no one could force a witness in precognition to say anything, and had the defender adopted that course nothing would ever have been heard of it, because it was quite evident that the husband would never have called him as a witness without knowing what he was going to say. Lord Kincairney, in giving judgment approved of issues (1) and (3). After reviewing the circumstances under which the action arose, he said that though the pursuer stated that the defender's statements were made maliciously, there was no averments from which malice could be inferred, and the idea of actual malice seemed preposterous and not in the case at all. The defender pleaded against the duplication of issues, but he saw nothing objectionable in this, there being a sufficient difference in the time and circumstances in which the words objected to were spoken, in private and at the trial, to warrant a separate issue for each occasion. Further, it seemed legitimate to put breach of confidentiality in one issue and defamation in another, as one issue might fail, and the other succeed, or the damages might be totally different in the two cases. There were, therefore, four issues to be disposed of. He had little difficulty in disallowing the fourth—an issue for defamation for evidence given in court on oath. Nothing was more

clearly settled than that in such a case the protection of a witness was absolute, whether his words were true or false, *bona fide* or malicious. He saw no ground for disallowing the third issue; the pursuer did not say that it referred to the precognition of the defender by pursuer's husband, and he did not see that that could be assumed. Even if it were, however, he had no doubt, that no absolute privilege attached to words spoken in precognition, and he was not prepared to say that they were privileged at all. He did not think malice could be added to that issue. The second issue was covered by the principle which afforded absolute protection to a witness, and was disallowed. The greatest difficulty was as to the first issue, but he thought it must be allowed. There seemed to be no other Scottish authority than a case in 1851, which was, however, quite conclusive, and, sitting in the Outer House, he considered he must follow it. The judgment applied to the action of Mr. Jones, the issues in his case being the same as in Mrs. McEwan's, except that the issue as regards confidentiality was omitted.

#### THE DIMINISHING BIRTH-RATE.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—The question of the diminishing birth-rate, which is so universal in almost all civilised European States and in English-speaking colonies, is, in my opinion, the greatest question in the domain of hygiene.

Notwithstanding the interesting statistics put forward in your issue of July 13th, by Dr. David Walsh, I think it is now well ascertained that, in the words of Dr. Billing, late Registrar-General of the United States, the recent fall in the birth-rate in civilised States or its most important cause is "the deliberate and voluntary prevention of child-bearing on the part of a steadily increasing number of married people, who not only prefer to have few children, but know how to attain that wish." Dr. Billing's views are readily seen to be true for the cities of the United States, for the "Statesman's Year-Book of 1902" mentions that the birth-rates per 1,000 persons in 1900 were, in New York, 22'50; in Chicago, 17'11; in Philadelphia, 20'50; in Saint Louis, 18'12; in Baltimore, 15'79; in San Francisco, 14'75; and in Cincinnati, 17'26. Compare these low birth-rates with that of London, 28'5; and recollect that in New Zealand, confessedly the most prudent of all countries in its birth-rate, where the birth-rate has fallen since 1880, when it was 40 per 1,000, to 26 per 1,000 in 1900, and Dr. Walsh may perhaps confess that Dr. Billing's account of the diminishing birth-rate is the true one. Ireland is an exception, for there, curiously enough, the marriage-rate is extremely low, whilst the births to each marriage are very high. I conclude that this is due to the power of the Catholic priesthood in Ireland, which is so diminished in France that a Bishop of that church lately had to petition the Vatican to forbid French priests to threaten communicants with censure who employed the methods referred to by Dr. Billing for keeping their families within their means of feeding them.

This new view of family life dates from 1877, when the important case of *Reg. v. Bradlaugh and Besant* came before the courts, and when I gave evidence for the defendants. In London, since then, some districts show a notable diminution in their birth-rates. Hampstead and Kensington, which in 1877 had birth-rates of over 35 per 1,000, have at present birth-rates of from about 18 to 20 per 1,000 inhabitants; while indigent districts, such as St. George's-in-the-East, have birth-rates of over 40 per 1,000. Now, high birth-rates in our cities mean high infantile mortality and crowding into purlieus like those of London, Dublin, Manchester, and Glasgow. The death-rate from phthisis, for instance, is six times as high in the poor streets of Brussels as in the wealthy classes living near

the park of that city, according to the late Dr. Janssens. I notice that Dr. Taylor, of Birmingham, thinks that the health of the wife is likely to suffer if she has only three or four children or less. But, of course, infinitely greater danger to the health of mothers and children is caused by large families when wages are low. In the Metropolitan Free Hospital, when it was situated in Whitechapel, I found that 100 married women over the age of forty-five had produced 720 children as a rule; and of these more than half had died in early childhood. On the other hand, Dr. Lutaud, of Paris, has shown in a letter to Mr. Hausmeister, of Stuttgart, that the wives of 100 medical practitioners of Paris gave birth to only 150 children—*i.e.*, to less than two children to a marriage. I found a similar state of things to exist in 1878 when I made an inquiry among French medical men on this point.

I submit to Dr. Taylor that the excellent physicians and surgeons of Paris cannot believe with him that small families are very hurtful to the health of their wives; but even were there a good deal of truth in his views it would be a remedy far worse than the disease to recommend more children to persons already overburdened with the care of those they were responsible for. I may perhaps, add that the health of children could not suffer from parental prudence if the three children required were born in the early years of the marriage. As to men, French physicians totally deny any injury done to their health by the innocent means they adopt to keep their families within their means of educating them. Marriage (*pace* the Catholic Church) is far more hygienic than singleness, which, as Sir Benjamin Brodie once said, produces "so many evils that he could not mention them, but which were even greater than the evils caused by prostitution." I presume he referred to masturbation and melancholia, etc.

Economically, however, it is out of the question for the people of any European State like ours to think of having large families with impunity. The censuses of the United States give us a clear proof of the population law, so well explained in 1798 by the great economist T. R. Malthus; for, in the year 1800 the population of the States was 5,308,000 and in 1830, 12,866,000; that is, it far more than doubled in thirty years, although between 1800 and 1830 there was scarcely any immigration from Europe into the States. Since 1800, while the inhabitants of the United Kingdom increased from 16,345,000 to 41,605,000 in 1901, or only about two and a half times in a century, the population of the United States increased from 5,308,000 in 1800 to 75,820,000 in 1900, or about fifteen-fold in that century.

The evident deduction from these facts is that we, in old countries like ours, must check population somehow, voluntarily or involuntarily; and the only question we have to solve is this—What is the least painful check we can devise? War, pestilence, and famine are intolerable; late marriages painful, and productive of prostitution and venereal contagion; emigration a delusion, as it removes one sex to the colonies and leaves the other in Europe, and because it tends to make people trust to a broken reed, besides becoming yearly more and more unattainable. Experience shows that we are even more crowded—as are the Germans—than ever with all our colonisation.

Hence we are now in the position to confess that we had better make up our minds that the best check to population consists in the producing—by *all* classes—whether rich or poor, of very restricted families such as four children as a maximum, or perhaps three or less on an average to each married couple, even although that restriction may occasionally be thought to slightly deteriorate the health of a few. "Of all evils choose the least" is the only true philosophy of the *homo sapiens*, and morality means for us moderns that conduct which tends towards minimising the preventable sorrows of our race. I am, Sir, yours truly,

C. R. DRYSDALE,

Consulting Physician to the Metropolitan Hospital of London.

### THE LUNACY QUESTION.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—What we want to do now is to arrange properly between doctors, lawyers, lunatics, and their friends or relatives. Doctors a few years ago were afraid to sign certificates, after the case of Weldon *v.* Whislow and Semple, and many feel now that they run risks in signing, even in undoubted cases. Where there is the least doubt no medical certificates can be obtained. When it was possible for a patient to be taken off to an asylum on the simple showing of two doctors' certificates, and nothing more, cases of malpractice did occur. Lunatic asylums were not nice places and Charles Reade showed them up.

Thank goodness, "tempora mutantur"; but how much of this is due to the medical profession is not very clear. Mrs. Weldon did some good, perhaps, but Dr. Semple's friends felt sorry for him. All that a doctor should be asked to do is to give a certificate of the mental condition of the case, much in the same way that he does of the physical, when filling up a form of insurance. There should be no doubt in the minds of friends, relatives, or lawyers about the doctors' perfect honour and honesty, and in this the readers of THE MEDICAL PRESS will agree.

I am Sir, yours truly,

R. L.

### THE MIDWIVES' INSTITUTE.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—In accordance with the request contained in the paragraph in your issue of 14th instant headed "The Midwives' Institute," we are instructed to say that the Incorporated Midwives' Institute never has been in any way connected or affiliated with the Midwives' Society referred to in such paragraph and consequently has not been absorbed in such Society. We are also instructed to request that you will, in your next issue, give publicity to this letter.

I am, Sir, yours truly,

BROWN, RINGROSE & LIGHTBODY.

18th July, 1904. Abingdon Street, London, S.W.

[We have much pleasure in inserting the above statement.—Ed.]

### THE ANNUAL TEMPERANCE BREAKFAST.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Will you kindly allow me to invite the attention of the profession to the Annual Temperance Breakfast which will be given by the National Temperance League at Oxford, on Thursday morning, 28th inst. The occasion will this year be of exceptional interest, in view of the recent memorial to the Educational Department, and of the evidence which we were enabled to present to the Physical Deterioration Committee of the Privy Council. I shall be glad if those who can attend will kindly apply for tickets at our table in the Reception Room.

I am, Sir, yours truly, JOHN TURNER RAE, Sec.

### Presentation to Professors Coffey and Ryan.

LAST week the governing body of the Catholic University School of Medicine with many of the past and present students met for the purpose of presenting two of the professors, Drs. Coffey and Ryan, with tokens of friendship on the occasion of their approaching marriages. Sir Christopher Nixon, Dean of the School presided, and while regretting that his colleagues' devotion to service would not in future take first place in their affections, he expressed the "respect which all entertained for their intellectual attainments, the admiration felt for their high personal character, for their unassuming charm of manner in itself an attribute of genius, and for their kindness of manner, which enforced the affection of all, colleagues, professional brethren, and students." Addresses were read to both gentlemen by the secretary of the Students' Committee and replies were made. Many scientific workers, to whom the labours of Dr. Coffey and Dr. Ryan in physiology and chemistry respectively have made them known, will join in the good wishes they have received from their immediate associates.

**Obituary.**

DR. W. A. M'KEOWN, BELFAST.

It is with great regret we record the death of William Alexander M'Keown, of Belfast, one of the best-known medical men in the North of Ireland. Though in indifferent health for some time, a serious result was not expected, and his sudden death on the 9th inst., was a shock to many. He was about sixty years of age, and had been in active practice as an ophthalmic surgeon since 1870. In this branch of surgery he made some notable advances, which are invariably connected with his name. Of these the most important were the introduction of the use of the magnet for the removal of metallic bodies from the eye-ball, and more recently his operative treatment of immature cataract. At the time of his death he had just accepted an invitation from the authorities of the Johns Hopkins Hospital to pay a visit to Baltimore, and demonstrate his method of procedure in this operation. He was intimately associated with all medical organisations in the North of Ireland and had been President of the Ulster Medical Society as well as of the North of Ireland Branch of the British Medical Association. Outside his surgical work, Dr. M'Keown was well known on account of the keen interest he took in all educational matters. On most points regarding the thorny subject of Irish education, primary, intermediate, and university, he held strong convictions, and he took care that they were known. Of vigorous courage and honesty of purpose, he was an acute controversialist, a hard hitter, and a good fighter. He was fixedly opposed to denominational education of every kind, and was, in consequence, a strong opponent of any scheme for the establishment of a Roman Catholic University in Ireland, while at the same time his objection to the clerical management of schools often brought him into conflict with the ministers of his own—the Presbyterian—Church. Not only by his professional brethren and the public of the North of Ireland is his death deplored, but by all those with whom, whether as ally or as opponent, he was brought into touch in public life.

GEORGE WILLIAMS PARKER, M.R.C.P.  
LONDON.

A CABLEGRAM from Georgetown, British Guiana, states that Dr. G. W. Parker, who arrived there from London in February in order to make collections of plants for Kew, and medicine plants for the British Pharmaceutical Society, has succumbed to an attack of malaria. Mr. Parker was cruising on a steam yacht when he was seized with fever. He was brought on shore in an unconscious condition, and died four hours later. Dr. Parker was formerly Court physician to the Queen of Madagascar. He was educated at St. Thomas's Hospital, London, and took the L.R.C.P. Lond. in 1872, the M.R.C.P. Lond., in 1883, and M.R.C.P. Edin, in 1878.

GEORGE ALDRIDGE GEORGE, M.R.C.S., L.R.C.P.

We regret to record the death, at Bournemouth, of Dr. G. A. George, formerly of Dorchester. He had been suffering for some time from diabetes, and on Monday week went to London to consult a specialist. He was the eldest son of the late Mr. Josiah George, Jun., of Romsey, a well-known brewer. He himself early in life had experience of banking, and was for a time manager of a branch bank in India. The failure of that banking business turned his attention into another channel—the main channel in which the current of his life thereafter flowed. Coming back to England, he resolved to study for the medical profession, and entered University College Hospital, London, where he passed as Licentiate of the Royal Colleges of Surgeons and Physicians in 1877.

**The Cholera in Persia.**

ACCORDING to a *Times'* telegram, the mortality from cholera in Persia is gradually decreasing, but there are still over 200 deaths daily. The districts surrounding Teheran are suffering severely.

**Laboratory Notes.**

BOVININE.

THE place of invalid restorative foodstuffs in the sick-room is now one of the commonplaces of medical practice. We have pleasure, therefore, in giving the following analysis of one of the best known of these products. A sample obtained by us yielded the following results:—

Total solids, 21.1 grammes per 100 c.c.

Mineral matter, 1.5 " " "

This mineral matter contained a little common salt, and the remainder appeared to be almost entirely phosphate of calcium.

The total solids, or residue left on drying, was almost entirely of a nitrogenous nature, and an estimation by Kjeldahl's method showed the sample to contain 18.2 grammes per 100 c.c. of albuminoids. As it was found that the preparation coagulated on heating, it appears to be a meat juice prepared by the cold process. We are opinion, considering the above facts, that this preparation should be of high nutrient and stimulating value, and we therefore have pleasure in commending it to the notice of our readers.

**FRIEDRICHSHALL.**

FRIEDRICHSHALL now enjoys a classical reputation in the field of medicine. This natural mineral water is described as a "pleasant, mild, and certain aperient." We are able to testify to this from personal experience, and a use of it extending over some years has confirmed the good opinion we have always held of it.

Its action depends on the sulphates and chlorides of sodium and magnesium that it contains, and we have now again analysed it with results that differ very slightly indeed from an analysis we made some years ago. The composition of the water is roughly as follows:—There are about two and one half per cent. of solids, which consist of the sulphate and chlorides of sodium and magnesium.

The taste is far from disagreeable, considering the amount and character of the salts present. However it is to be explained the fact remains that the mineral salts naturally occurring in waters of this character are more efficacious and less unpleasant to take than solutions of the same salts artificially prepared.

**ANGOSTURA BITTERS.**

WE have examined a sample of this well-known brand of bitters procured from the original manufacturers, Messrs. J. G. B. Siegert and Sons, and consider that the results we have obtained in the laboratory, combined with a practical experience extending over more than ten years, justify us in stating that the claims made for it by the makers are in no way exaggerated. As many imitations of these well-known "bitters" are put up by chemists and other manufacturers, some of which contain cinchona preparations and various kinds of bitter principles, it is obvious that a standard preparation compounded by the original makers is much to be preferred to fictitious imitations. The original preparation has frequently been examined and approved by well-known analysts, and in the present case we have ourselves carefully analysed and searched for all possible deleterious substances and have found them entirely absent. The preparation contains alcohol to the extent of about 50 per cent. of absolute alcohol, and about 6 per cent. of solid residue, and only 0.5 per cent. of mineral matter, which shows that the bitters are purely vegetable in their composition.

**Literary Notes and Gossip.**

"THE Queen Newspaper Book of Travel" (London: Horace Cox, 1904. Price 2s. 6d.), is a dainty little volume, handy in shape, concise in matter, eminently practical in service, and is a *resumé* of travel information that has appeared in the pages of the *Queen* from 1894 up to the present year. Useful particulars of various health and holiday resorts in the United Kingdom, Europe, and even Africa, are given, arranged in

convenient alphabetical form. It is evidently a guide book for the wealthy traveller, but also contains hints and suggestions which should be of value to many a physician when selecting a suitable resort for his patients. \*\*\*

WE understand that Dr. Ralph W. Leftwich has thoroughly revised his "Index of Symptoms," of which a third and considerably enlarged edition will be published by Messrs. Smith, Elder and Company immediately. The last edition had a somewhat bald appearance from the multitude of unbroken columns. This has been remedied by breaking up the last chapter on "Methods of Diagnosis," and inserting its different parts under their respective headings. \*\*\*

THE Royal Statistical Society announces that the subject of the essays for the Howard Medal, which will be awarded in 1905, with £20 as heretofore, is "A Critical Inquiry into the Comparative Prevalence of Lunacy and other Mental Defects in the United Kingdom during the last Fifty Years." \*\*\*

"THE Seaside and Inland A B C Holiday Guide" (London: Wentworth Publishing Company), is a well-arranged, concise, but somewhat scantily illustrated handbook of useful information for tourists and holiday seekers, which should prove of much service to those desirous of readily gaining trustworthy information regarding many of our British health stations. Medical men will find this little manual useful for purposes of rapid reference. \*\*\*

"WHERE to Stay" (London: The Gordon Hotels, Limited) claims to be the official guide to the best hotels in the United Kingdom and abroad. It is an excellent alphabetically arranged illustrated guide, which should prove invaluable to travellers; and physicians having to advise patients in the choice of desirable residential quarters in various health resorts would do well to have a copy of this little work within reach. \*\*\*

New editions of two important standard works have just made their appearance—viz., a fourth edition of Dr. Dawson Turner's "Manual of Practical Medical Electricity," and a second edition of Messrs. Robson and Moynihan's "Diseases of the Stomach and their Surgical Treatment." In the former, Röntgen rays, Finsen light, radium, and High-frequency currents receive fuller treatment, and thirty fresh illustrations have been added; and in the latter volume the authors state that "the whole work has undergone most careful revision," and many new illustrations have been added. Both works are issued by Messrs. Bailliere, Tindall and Cox. \*\*\*

THE *Journal* of the Royal Army Medical Corps, edited by Colonel David Bruce, F.R.S., R.A.M.C., contains many papers of scientific and literary excellence. Among the articles may be specially noted those on "Enteric Fever" by Captain E. Blake Knox, R.A.M.C., and by Captain W. S. Harrison, R.A.M.C. The former deals with the spread of enteric fever by urine and its prophylaxis, and the latter with our present position with regard to enteric fever in India. These papers are of value in attacking the ever-present problem of enteric fever in India. A paper on "Sleeping Sickness in Uganda" is contributed by Colonel Bruce. \*\*\*

NURSE GOLDIE'S "Notes on Home Nursing," is a useful repertory of practical hints compiled for the benefit of untrained persons who are called upon to render first aid in emergencies or nursing assistance to the sick in their own homes. In such a small volume the author could not possibly attempt to systematise, but she has managed to touch on all the points likely to be of interest to the general reader. We have our doubts as to the utility of giving directions for bandaging without the help of illustrations, but in such a dainty volume really there is no room for the latter. In short, these "Notes" constitute a very handy portable work of reference for family and general use. \*\*\*

A PAPER of considerable importance was communicated at the last meeting of the Royal Society by Sir Thomas R. Fraser, M.D., F.R.S., of Edinburgh, and Major R. H. Elliot, of the Indian Medical Service, who have been conducting a research into the action of snake venoms. They find that the most deadly of all substances of this nature which they have examined is the venom of the sea-snake, *Enhydrina valahadiensis*—resembling, but more lethal than, that of the cobra. This sea-snake has, of course, nothing to do with the so-called sea-serpent, and is chiefly found in the Indian Ocean. \*\*\*

#### Society for the Relief of Widows and Orphans of Medical Men.

At the quarterly Court of Directors of this Society held on Wednesday last, the President, Mr. Christopher Health, being in the chair, two new members were elected, the deaths of three members reported, and two gentlemen had ceased to be members of the Society. A grant at the rate of £50 per annum was made on the application of a widow. The deaths of two widows were announced; one aged 81, had been in receipt of grants since January 1877, and had received £1,540 from the Society, her husband had only been a member ten years, paying 20 guineas; the other, who had just entered her 101st year, had received £1,245, having been on the funds of the society since January 1882, the husband had paid 32 guineas subscriptions. The death of an orphan was reported, who had been on the Copeland Fund since 1866, and had received £452. A legacy of £1,000 had been paid by the executors of Mrs. Du Pasquier. The expenses of the quarter amounted to £52 12s. 6d. \*\*\*

#### Royal University of Ireland.

THE examiners have recommended that the following candidates be adjudged to have passed the First Examination in Medicine, Summer, 1904:—John B. Aickin, Thomas P. Carroll, James K. P. Clarke, Michael Connell, Victor L. Connolly, Gertrude C. Corscadden, Nicholas Cunningham, George Deery, Elliot P. Dewar, Charles Dickson, William P. Dunne, B.A., Michael P. Fitzgerald, Hugh J. Grant, Edmund J. Harty, Joseph Horan, John C. Johnson, Thomas Kennedy, Peter J. Keogh, Joshua Keyms, Alan Kidd, William C. M. Lewis, William P. MacArthur, Samuel W. M'Combe, Thomas C. MacGowan, Mathew J. M'Grath, Michael M'Niff, Henry H. MacWilliam, Patrick J. Mockler, Kenneth F. Mulligan, Ulick J. G. Mulligan, Daniel F. Murnaghan, Harris Newman, Peter H. O'Connell, William M. J. O'Connor, William D. O'Kelly, William F. O'Regan, Alexander Patton, John F. Rahilly, Alfred H. Rentoul, Robert H. Robinson, John A. Sinton, William Speedy, Robert S. Taggart, Gerald J. W. Tierney, William Tyrrell, Bruce A. West, John M. Williams, Joseph A. L. Wilson. \*\*\*

The undermentioned candidates have qualified on their answering to present themselves for the further examination for Honours in the subjects set after their names. Those qualified in two or more subjects may present themselves for the Honour examination in all subjects:—James K. P. Clarke, zoology; Charles Dickson, chemistry; William P. Dunne, B.A., zoology and physics; Michael P. Fitzgerald, botany; Hugh J. Grant, chemistry and physics; John C. Johnson, botany, chemistry, and physics; Joshua Keyms, physics; Alan Kidd, botany; William C. M. Lewis, chemistry and physics; William P. MacArthur, chemistry; Henry H. MacWilliam, botany, zoology, chemistry, and physics; Kenneth F. Mulligan, botany, zoology, chemistry; Peter H. O'Connell, physics; William D. O'Kelly, botany, zoology, chemistry, and physics; Alfred H. Rentoul, botany and zoology; Robert H. Robinson, botany and chemistry; John J. Sheil, physics; John A. Sinton, botany, zoology, and physics; Bruce A. West, botany and physics. \*\*\*

The examiners have recommended that the following candidate be adjudged to have passed the examination for Diploma in Sanitary Science:—Dennis J. Collins, M.B., B.Ch., B.A.O., Royal Army Medical College, London. \*\*\*

## Notices to Correspondents, Short Letters, &c.

**✉** CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive Signature or Initial*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

ORIGINAL ARTICLES or LETTERS intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

CONTRIBUTORS are kindly requested to send their communications, resident in England or the Colonies, to the Editor at the London office; if resident in Ireland, to the Dublin office, in order to save time in re-forwarding from office to office. When sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

THE *Dail Chronicle* states that last week near University College Hospital, the body of an infant was found wrapped in paper, on which was written: "To the Professor of Anatomy, Middlesex Hospital."

T. P. O'CONNOR, in his *Weekly*, quotes the following verses anent a notorious quack of the last century from the "Epitaph on a Fair Patient of St. John Long's." "St. John Long was a Tipperary man, one O'Driscoll, who was first employed by Sir Thomas Lawrence, then by doctors for whom he prepared anatomical drawings, and then by a gullible public whom he doctored himself. The young lady on whom Ingoldsbys wrote the epitaph died from the exhaustion of a frightful wound in her back produced by the embrocation:

Hic jacet in terra  
Pulchra puella:  
Volvit esse melior  
Dum fuit wella.

Qua causa mortis  
Infelix virgo?  
Aqua fortis  
Urens a tergo!  
Medicus? Nequaquam.  
Sed pictor signorum,  
In Tipperaria  
Inops bonorum.

Nunc dives auri  
Sedet sublimis  
In curru, celebratus  
Prosa atque rhyms!

Ah! virgo infelix!  
Hic intus jace  
In longum a Longo  
Requiescat in pace!

"T.P." could not resist adding an English epitaph on St. John himself with as happy a pun upon his name as "in longum a Longo":

Behold, ye quacks! the vengeance strong  
On deeds like yours impinging;  
For here below lies *St. John Long*,  
Who now must be *long singing*.

C. H. SEES (Brighton).—We do not really recall the name of one really famous scientific man in the New World or the Old who does not accept Darwin's theory as to the evolution of man from lower forms of life. There were a few distinguished scientists in opposition some years ago, but death has removed them from the scene.

### THE INEBRIATES ACT.

A SUBSCRIBER.—Dipsomania is not regarded in law as a form of insanity, so that it is difficult to apply compulsion. Under the recent Act means are provided for dealing with confirmed inebriates, but they still fall short of requirements. It is not even regarded as a sufficient reason for judicial separation.

A FOURTH YEAR'S MAN.—(1) Aillingham's "Operative Surgery" would answer your requirements admirably, and you might supplement this with "The After Treatment of Operations" by J. Lockhart Mummery. (2) Phillip's "Materia Medica and Therapeutics." (3) May, Swansy or Lawson, on "Diseases of the Eye."

A STUDENT OF SOCIOLOGY.—Your letter will appear in our next issue.

## Meetings of the Societies, Lectures, &c.

WEDNESDAY, JULY 20th.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chenies Street, W.C.)—4 p.m. Mr. J. Smith: Clinique. (Surgical.)

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chenies Street, W.C.)—4 p.m. Mr. Hutchinson: Clinique. (Surgical.)

THURSDAY, JULY 21st.

MOUNT VERNON HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST (7 Fitzroy Square, W.)—5 p.m. Dr. H. Scharlieb: The Administration of Anaesthetics in Affections in the Respiratory System.

## Vacancies.

Ayr District Asylum.—Assistant Medical Officer.—Salary £120 per annum, with board, furnished apartments, attendance, and washing. Applications immediately to the Medical Superintendent.

Berkshire Asylum, Wallingford.—Second Assistant Medical Officer. Salary £140 per annum, with board, furnished apartments, attendance, &c. Applications to Medical Superintendent.

Carlisle Non-Provident Dispensary.—Resident Medical Officer. Salary £150 per annum, with apartments (not board). Applications to the Honorary Secretary, Mr. G. A. Lightfoot, 23 Lowther Street, Carlisle.

Combined Sanitary District of West Sussex.—Medical Officer of Health. Salary £650 per annum to include all travelling expenses. Applications to A. C. Coole, Solicitor 9 Carfax, Hoveham.

Dorset County Hospital, Dorchester.—House Surgeon.—Salary £100 per annum. Applications to W. E. Groves, Valetta, Icenway, Dorchester.

Stirling District Asylum, Larbert, N.B.—Assistant Medical Officer. Salary £150 per annum, with board, &c. Applications to the Medical Superintendent.

Township of Toxteth Park.—Resident Medical Officer. Salary £100 per annum, with board, washing, and apartments. Applications to J. Moulding, Clerk to the Guardians, 15 High Park Street, Liverpool.

Wolverhampton and Staffordshire General Hospital.—House Surgeon. Salary £100 per annum, with board, lodging, and washing. Applications to Edmund Forster, House Governor and Secretary.

## Appointments.

BARTLETT, R. C., M.B.E.C.S., L.E.C.P.Lond., Certifying Furgreen under the Factory Act for the Romsey District of the County of Hants.

BUSHNELL, F. G., M.D.Lond., D.P.H.Cantab., Pathologist to the Sussex County Hospital.

JOINTON, HENRY M., B.A., M.B., Chief Demonstrator of Anatomy in Trinity College, Dublin.

TAYLOR, GERRARD C., M.D.Cantab., D.P.H., Medical Officer of Health of the Urban District of Finchley.

WALKER, H. J., M.B., M.S. Edin., Certifying Surgeon under the Factory Act for the Brighton District of the County of Sussex.

## Births.

BUZZARD.—On July 15th, at 74 Grosvenor Street, W., the wife of E. Farquhar Buzzard, M.D., of a daughter.

CROCKER.—On July 13th, at Gort House, Petersham, Surrey, the wife of J. Hedley Crocker, M.D., of a daughter.

DIXON.—On July 12th, at Lynwood, Haven Green, Ealing, the wife E. Halstead Dixon, M.B.Lond., of twin daughters.

## Marriages.

LEGGATT-ANDERSON.—On July 14th, at St. Mary Abb'tt's, Kensington, Allen Worth Leggatt, son of the late H. Bethune Leggatt, to Lucy Hosack, second daughter of Izzet Anderson, M.D.Edin., of 23 Arundel Gardens, W.

OLIVER-BIGGS.—On July 12th, at All Saints' Church, Peckham, S.E. J. Latham, elder son of John B. Oliver, M.D., of 59 Parkfield Road, Liverpool, to Nellie third daughter of C. H. W. Biggs, Esq., of Glebe Lodge, Champaign Hill, London, S.E.

## Deaths.

KENNY.—On July 10th, at West Coker, near Yeovil, Jane Kenny, widow of the late John Kenny, Esq., of Dublin, surgeon, aged 87.

MARSHALL.—On July 13th, at Church House, Mitcham, Edward Marshall, M.R.O.S.E., L.S.A., aged 78.

## OPERATIONS.—METROPOLITAN HOSPITALS.

WEDNESDAY.—St. Bartholomew's (1.30 p.m.), University College (2 p.m.), Royal Free (2 p.m.), Middlesex (1.30 p.m.), Charing Cross (3 p.m.), St. Thomas's (2 p.m.), London (2 p.m.), King's College (2 p.m.), St. George's (Ophthalmic, 1 p.m.), St. Mary's (2 p.m.), National Orthopaedic (10 a.m.), St. Peter's (2 p.m.), Samaritan (9.30 a.m. and 2.30 p.m.), Gt. Ormond Street (9.30 a.m.), Gt. Northern Central (2.30 p.m.), Westminster (2 p.m.), Metropolitan (2.30 p.m.), London Throat (9.30 a.m.), Cancer (2 p.m.), Throat, Golden Square (9.30 a.m.), Guy's (1.30 p.m.).

THURSDAY.—St. Bartholomew's (1.30 p.m.), St. Thomas's (3.30 p.m.), University College (2 p.m.), Charing Cross (3 p.m.), St. George's (1 p.m.), London (2 p.m.), King's College (2 p.m.), Middlesex (1.30 p.m.), St. Mary's (2.30 p.m.), Soho Square (2 p.m.), North-West London (2 p.m.), Chelsea (2 p.m.), Great Northern Central (Gynaecological, 2.30 p.m.), Metropolitan (2.30 p.m.), London Throat (9.30 a.m.), St. Mark's (2 p.m.), Samaritan (9.30 a.m. and 2.30 p.m.), Throat, Golden Square (9.30 a.m.), Guy's (1.30 p.m.).

FRIDAY.—London (2 p.m.), St. Bartholomew's (1.30 p.m.), St. Thomas's (3.30 p.m.), Guy's (1.30 p.m.), Middlesex (1.30 p.m.), Charing Cross (3 p.m.), St. George's (1 p.m.), King's College (2 p.m.), St. Mary's (2 p.m.), Ophthalmic (10 a.m.), Cancer (2 p.m.), Chelsea (2 p.m.), Great Northern Central (2.30 p.m.), West London (2.30 p.m.), London Throat (9.30 a.m.), Samaritan (9.30 a.m. and 2.30 p.m.), Throat, Golden Square (9.30 a.m.), City Orthopaedic (2.30 p.m.), Soho Square (2 p.m.).

SATURDAY.—Royal Free (9 a.m.), London (2 p.m.), Middlesex (1.30 p.m.), St. Thomas's (2 p.m.), University College (9.15 a.m.), Charing Cross (2 p.m.), St. George's (1 p.m.), St. Mary's (10 p.m.), Throat, Golden Square (9.30 a.m.), Guy's (1.30 p.m.).

MONDAY.—London (2 p.m.), St. Bartholomew's (1.30 p.m.), St. Thomas's (3.30 p.m.), St. George's (2 p.m.), St. Mary's (2.30 p.m.), Middlesex (1.30 p.m.), Westminster (2 p.m.), Chelsea (2 p.m.), Samaritan (Gynaecological, by Physicians, 2 p.m.), Soho Square (2 p.m.), Royal Orthopaedic (2 p.m.), City Orthopaedic (4 p.m.), Great Northern Central (2.30 p.m.), West London (2.30 p.m.), London Throat (9.30 a.m.), Royal Free (2 p.m.), Guy's (1.30 p.m.).

TUESDAY.—London (2 p.m.), St. Bartholomew's (1.30 p.m.), St. Thomas's (3.30 p.m.), Guy's (1.30 p.m.), Middlesex (1.30 p.m.), Westminster (2 p.m.), West London (2.30 p.m.), University College (2 p.m.), St. George's (1 p.m.), St. Mary's (1 p.m.), St. Mark's (2.30 p.m.), Cancer (2 p.m.), Metropolitan (2.30 p.m.), London Throat (9.30 a.m.), Royal Ear (8 p.m.), Samaritan (9.30 a.m. and 2.30 p.m.), Throat, Golden Square (9.30 a.m.), Soho Square (2 p.m.).

## Original Communications.

### COLOTOMY & COLECTOMY. (a)

By FRANK T. PAUL, F.R.C.S.,  
Surgeon, Royal Infirmary, Liverpool.

THE operation of colotomy has always attracted much interest. In my earlier days, when laparotomies were regarded with a serious suspicion, colotomy was the most popular of abdominal operations, and ranked in the appreciation of surgeons with lithotomy or the ligation of large arteries. From 1878 to 1889, when opportunity offered, I did, as other surgeons did, the classical lumbar operation; but when H. A. Reeves, Harrison Cripps and Herbert Allingham roused our attention in this country to the advantages of anterior colotomy, I followed their lead, and soon became convinced that it was correct.

There is no need now to revive the discussion as to which is the better operation. The first place was soon conceded to anterior colotomy, and year by year its success has become more firmly established.

Some ten years ago the value of colotomy in cases of rectal cancer was discussed at this Society. At that time several of the most experienced members of our Medical Institution were only prepared to advocate it as a means of giving relief when the most urgent and distressing symptoms were present. I remember it was classed with gastrostomy and gastro-enterostomy for malignant stricture as dangerous to life, and producing other ills almost if not altogether as unpleasant as those it was designed to relieve.

We may truly say now that we have changed all this, not only for colotomy, but for gastrostomy and gastro-enterostomy as well, but especially as regards colotomy. And one feels now that it is right to recommend the latter in any case of rectal cancer unsuitable for excision in which distressing symptoms are present or are indicated. Indeed, enthusiasts (and I may include myself) for high operations in extensive rectal cancer seem to be inclining again to substitute a permanent iliac colotomy for these very serious and wide operations; or to do it as a preliminary, and so lessen the risk of the subsequent proceeding.

Modern colotomy has unquestionably gained in favour, and this gain is due to two causes:—

1. Lower mortality.
2. Improved artificial anus.

The latter has, I consider, been the more important factor, for when a patient is labouring under a mortal disease it is more a question of comfort and the capacity to continue one's daily avocation than the simple prolongation of a more or less miserable existence. In the discussion to which I have referred, it seemed to be strongly felt that the discomforts of the artificial anus were frequently as great as those of the malignant ulceration. The want of control over the evacuations, the dependence upon assistance after each movement of the bowels, and the rather frequent occurrence of prolapse certainly rendered the life of a colotomy patient a far from happy existence. Now usually

very fair control is established in most cases, and prolapse hardly ever occurs; whilst with an anterior opening the patient can attend to himself a condition of independence which is greatly appreciated by the good, hopeful, deserving class of patients. I have no sympathy with those who give in. It is the duty of all of us not only to live but to work as long as we are able; and it is, as we all know, quite possible for any colotomy patient, not otherwise disabled, to do his daily work, whether active or sedentary, when the artificial anus is a good one.

Among the various suggested methods for doing iliac colotomy it must be conceded that, at any rate in England, Mr. Harrison Cripps' is that which has met with most general favour. Indeed, Mr. Allingham, who advocated a rival method, has of late accepted the former, except in cases in which the sigmoid mesentery is long, and the patient may be expected to survive a considerable time. In my judgment, Mr. Allingham's present position is a wise one. The variability of the anatomical conditions of the sigmoid flexure is such as to render it impossible that the same method of dealing with it can be the best for every case. And it certainly seems the fact that when the flexure is voluminous and its mesentery long, Cripps' method, however carefully accomplished, is very likely to be followed by a moist, patulous anus, over which it is difficult to create any control, and through which prolapse of bowel is very probable. Allingham's procedure is undoubtedly rather more severe; but it results in an excellent orifice, and the increased comfort when the operation is properly indicated is well worth the increased risk.

One desires from a colotomy—

1. Relief.
2. Safety.
3. Comfort.

First, as to relief. In cases of obstruction immediate relief is urgent. This perhaps applies to 20 per cent. of the cases; less when the disease is in the rectum, but more when it is in the colon. When the operation is undertaken with the necessity of giving immediate relief, I urge the glass-tube method, and I may do this with more confidence now than in 1891, when I first introduced it; for not only has my personal experience of the method been fairly considerable since that time, but I gather that it is now generally practised under these circumstances. Cripps' and Allingham's operations do not provide for the immediate opening of the bowel, but I have practised both operations many times and under all sorts of circumstances in conjunction with the glass tube, and have no reason to think that these operations are rendered appreciably more dangerous thereby. If this experience is correct, and it is true—as I believe it to be—that opening the bowel at the time of the primary operation does not appreciably increase the risk of life, then it is certainly a desirable addition in most cases; for not only is it convenient that the bowel should be open and free for the passage of flatus and fæces, but the wound in the abdominal wall may be smaller, a point of some importance, and the operation is completed at one sitting. There is no occasion for the subsequent incision and later paring of the mucous membrane required in Cripps' operation,

(a) Read at the Liverpool Medical Institution, Feb. 12th, 1903.

and no subsequent clamping and removal of bowel as in Allingham's. I therefore distinctly recommend that in doing either of these operations the glass tube should be used and the bowel opened at once, whether obstruction is present or not.

Next as regards safety. When the patient is in an exhausted condition, Cripps' operation, with or without the tube, should be selected, as the removal of bowel, especially if the mesentery be thick, increases the risk. Should obstruction be present, in introducing the tube every precaution must be taken to avoid leakage. In all cases both the bowel and the tube should be attached to the abdominal wall, the bowel by passing at least two green-gut sutures between it and the deep muscular aponeurosis, and the tube by passing its silk ligatures through the skin and knotting them. Then, if the tube is accidentally dragged on, it is well and safely anchored, and when it comes away, if the adhesions between the bowel and the parietal peritoneum are weak, they are backed up by the green-gut sutures.

As regards comfort, the essentials are—(1) A high operation, a small wound, and opening the highest portion of colon available, as recommended by Harrison Cripps. (2) The formation of a good spur. (3) Embodying the principle of Allingham's operation, whenever the sigmoid flexure is voluminous and its mesentery long, and the patient sufficiently robust to make this wise. (4) The use of a good plug, and the cultivation of a regular habit of bowels. After various trials with trusses and belts, I have come to use an aluminium mushroom plug made for me by Mr. Reynolds, of Liverpool. The plug or stalk is slightly bulbous, and long enough to pass through the whole depth of the abdominal wall. The head or flange is oval-shaped and wide; it is slightly concavo-convex, to fit the abdominal surface. A single layer of soft lint, with a hole in the middle for the stalk, is placed under the flange, and a good pad of cotton-wool above it, the whole being kept

ALUMINIUM COLOTOMY PLUG.

in place by a narrow abdominal belt such as I use after appendicectomy. This is the cleanest and far the most comfortable and effective apparatus I have yet tried.

In 1898 I designed an operation to give better control over the artificial anus. It involved using Madelung's method of closing and returning the rectal end of the bowel into the abdominal cavity, while the upper end was brought out at a distance after having passed between the muscles—in fact, after the principle of Hahn's or Frank's gastrostomy. The operation was effective but dangerous. It was unnecessarily severe, and in passing the bowel between the muscles septic infection was liable to occur. For these reasons I soon abandoned it, and I think now that sufficiently good control can be obtained by ordinary methods.

The details of a colotomy by the glass-tube method are as follows:—

1. The incision is made in accordance with accepted principles, but may be smaller, that is,  $1\frac{1}{2}$  to 2 inches, according to the condition of the abdominal wall and the bowel.

2. If the mesentery be very short, the bowel is firmly drawn out and a running suture of medium thick silk inserted round an oval area involving as much of the circumference of the bowel as possible, so as to ensure its posterior wall being well brought up to the surface to form a good spur. The enclosed area is then gripped with two catch forceps, incised, the tube plugged with wool inserted, and the ligature tied. A second silk ligature is then simply tied over the first to render it more secure, and is knotted on the opposite side of the

tube. Two or more green-gut sutures are next passed between the outer coats of the bowel and the deep tissues of the wound, and finally the ends of the silk ligatures are passed through the skin and tied so as to secure the tube in case of roughness or accident. Usually the wound is too small to need any further sutures. The parts being septic are well powdered with iodoform, and dressed with cyanide gauze and wool as usual, and a binder split to transmit the tube is firmly applied. If the bowel be empty, a light plug of wool is kept in the tube. If loaded with formed motion a sponge bag containing some iodoform wool or wool sprinkled with eucalyptus oil is attached. If with loose motion a short piece of Down Brothers' thin wide indiarubber tubing is attached to the glass tube and allowed to fall into a basin at the patient's side.

3. If the mesentery be long and the patient in good condition, the loose loop of sigmoid flexure should be drawn out, the mesentery ligatured separately, a large tube fastened into the top end and a small one into the bottom end, and then all the redundant bowel cut away. It is better not to ligature the mesentery together with the bowel to the tubes, as, unless the grip is very tight, some of the vessels are liable to draw out, and smart hæmorrhage may result. It will be found much safer to tie the mesentery in two or three sections by itself. When the sigmoid mesentery is of medium length either method may be used, but in all cases when doing Cripps' operation, care must be taken to insert the tube into the highest portion of bowel which can be brought out of the wound, and to include the whole or almost the whole circumference of the bowel.

Usually on the fifth day the tube is ready to come away. When this is the case, indicated by leakage beside the tube, the silk sutures are cut and it is withdrawn.

4. Subsequently, the patient is kept in bed, the motions being passed into the dressings until the wound is healed, when the plug and belt are worn.

*Colotomy in other regions.*—For some time I maintained it was our duty to do colotomy as low down in the bowel as we could, consistently with being well clear of the disease. Now I am inclined to think that there are only two good colotomies, sigmoid and transverse. In the few cases in which I have had to do the latter it has answered very fairly well. Not so well as sigmoid, but decidedly better, I consider, than the lumbar operation. Right iliac colotomy I do not like at all; the motions are liquid, and quite uncontrollable. I never do it except in cases of obstruction, and then only in the hope and expectation that subsequent enterectomy or short-circuiting will be possible. When the cæcum is opened only a small tube should be used, one of  $\frac{1}{2}$  to  $\frac{3}{4}$  inch diameter being sufficient.

It has been said that subsequent trouble will result if either the sigmoid or the cæcum is opened and attached in the middle line. I have had to do this occasionally, and in practice no inconvenience has resulted. One would never choose this position, but at any time there may be urgent reasons why one should accept it.

The operation of colotomy is so closely associated with that of colectomy that I can hardly treat of one without reference to the other. Often when colotomy only is intended before exploration, colectomy is ultimately undertaken, or the reverse may be the case; while, as I have stated, it is no unusual thing for me to cut away several inches of colon, with the simple object of improving the character of an artificial anus. When, however, the original intention is colectomy, there are a few additional points which need careful consideration. The chief of these are, the exact location of the disease and the restoration of the continuity of the bowel.

It is a great misfortune that malignant disease of the colon is so very undemonstrative in its early stages. Recently, in one week, I was asked to see three cases, all too late for operation; that is, in all the tumour was hopelessly adherent to neighbouring important structures. This form of cancer is one of the least malignant with which I am acquainted; and could one obtain the cases early enough, as happens more

frequently in the rectum, the results would be excellent. In its first stage, however, it apparently sets up no recognisable symptoms, and I have no doubt it often exists for several months, or a year or two, according to the type of growth, before any evidence whatever of its presence is afforded. The earliest symptoms are frequently those of intestinal indigestion, brought about by some difficulty in the contents of the bowel passing the diseased part. They are flatulence, slight colicky pains, some distension, and irregularity of the bowels. In other cases there are no obstructive symptoms at first, but mucus and perhaps blood appear in the motions. At a later stage some obstruction is usually present, characterised by increasing constipation, with attacks of colicky pain. Loss of flesh occurs, and ultimately a tumour is discovered in some cases, while in others the surgeon is called in because complete obstruction has supervened. The clinical details are influenced by the character of the growth. From 35 to 45 or 50 the disease is generally of the fungating type, and produces more of a tumour than an ulcer. In these cases there is often no obstruction, but plenty of mucus and blood in the motions. The abdomen is not distended, and if carefully palpated the tumour might usually be discovered much earlier than it is. Still one must bear in mind that the patient suffers little, and frequently makes no complaint until it is too late. Indeed, it is sometimes the discovery of the tumour by the patient himself that leads him to consult his doctor. From 50 to 70 or 80 the growth is usually of the chronic ulcerating type, producing the ring stricture. In these cases the symptoms are almost entirely due to obstruction, which in the end generally becomes complete, owing to the narrow lumen at the strictured part (often only transmitting a No. 10 catheter) becoming blocked by some coarse undigested substance in the *faeces*.

When distension is absent a tumour is often present, and in this way the disease is usually located in the younger class of patients; but after obstruction has once set in, it is rare to be able to detect a lump, and one must be guided in other ways in locating it. Probabilities are of no help. One must never cut down over a particular region because that is statistically the most probable site of the disease. In the absence of stronger evidence exploration in the middle line should be the practice. The best aids to diagnosis are the capacity of the bowel below the stricture, the condition of the *cæcum* and colon as made out by percussion and palpation, and the evidence afforded by pain and peristalsis. The patient is often quite conscious of the site of the stricture, having many a time felt a colicky wave of peristalsis pass away at a particular spot with a gurgling sound, as gas and liquid were forced through the stricture. And when the bowel is much hypertrophied, one may see the peristaltic wave gather and run on until it comes to a stop at the stricture. The enema, too, is a great help when the disease is low down. As the result of experiment on the dead subject, I believe the bowel will hold something like two pints with an obstruction in the sigmoid flexure; but in actual practice one finds that half a pint to a pint is all that is tolerated, usually the former, and that it is returned at once without motion. Under these circumstances the tumour is in the most favourable place for operation. When it is higher up large quantities of injection may be introduced and retained. One has then to be guided chiefly by palpation and percussion of the regions of the large bowel, and if nothing definite can be made out a middle-line exploration should be undertaken.

When the tumour is located it must be freely exposed, and if suitable for removal the mesentery in connection with the part involved is carefully divided, so that the diseased coil of bowel may be brought out of the abdomen. The subsequent steps of the operation depend upon the mode of union to be attempted, and in regard to this I continue to differ strongly from those who consider primary end-to-end union by suture or button the proper course to adopt as a routine practice. That it is the neatest and most satisfactory to the surgeon when the patient lives I do not doubt; but it

is certainly more dangerous, without ultimately being at all more efficacious than when the ends of the bowel are brought out, and the continuity of the canal subsequently restored. When this is done it is a rare thing to lose a patient who is not at the time of the operation seriously depressed as the effect of several days' obstruction of the bowels. In this connection I may, as a surgeon, warn my medical friends that a patient after ten days' obstruction in the lower bowel is in much worse case than his pulse and appearance seem to indicate. One is asked to do colotomy under these circumstances with the assurance that the patient is in excellent condition. It is true that he is quite fit to bear the operation, but when he dies a few days later, death should be ascribed to the absorption of toxins, which is the cause of it, and not to the operation, which has had nothing to do with the unfortunate result.

I commenced operating by bringing out the ends of the bowel in 1892, and after ten years' experience am strongly confirmed in my opinion that it is the right thing to do. I know nothing against it, except that the patient has the discomforts of an artificial anus for a few weeks, and the course of the case is prolonged by about a month—small evils compared with the gravity of the disease and the risks of end-to-end union. It has been suggested that stricture might result from

incomplete removal of the spur, but such has not proved to happen in any of my cases.

After dividing the mesentery the subsequent steps of the operation are of the simplest. The tumour being well drawn out of the abdomen, the ascending and descending portions of the colon are made to lie side by side, like the barrels of a double-barrelled gun, in which relationship they are lightly sutured together for quite three inches inside the abdomen. Outside the abdomen a colotomy tube is ligatured into the upper end and a smaller tube into the lower end, when the diseased part is cut away, of course quite bloodlessly. A few fine sutures may be used to attach the bowel to the parietal peritoneum at the bottom of the wound, and if the incision has been long, its ends are brought together with fishing-gut sutures.

In many cases the operation is very little more severe than colotomy. Five or six days later the tubes separate, and at the end of three weeks, as a rule, the

carefully prepared spur may be clamped. I once had a warning that this should not be done too hastily.

CLAMP FOR REMOVING SPUR AFTER ENTERECTOMY.

After complete obstruction the bowel is liable to be in a very septic and irritable condition, and so long as the spur feels thick and hard to the finger I believe it to be unwise to apply the clamp. As a rule it is supple throughout, and under these circumstances may be clamped at any time. One clamping is very likely to be insufficient, and if there is a considerable ridge still apparent at the bottom the clamp should be applied again. It need not be kept on each time until it comes away, as its work is thoroughly effected in forty-eight hours, when it is probably safer removed than left *in situ*. Messrs. Down Brothers have recently made me a new clamp, which has proved very useful. The compression is maintained by a steel spring on a projecting arm, which can be disengaged to facilitate introduction. As soon as the spur is completely destroyed the artificial anus is closed. The entire operation has been completed in twenty-four hours, but usually six to eight weeks must be allowed for it. In cases of malignant disease of the colon in which the mesenteric glands are involved I used to give a most depressing prognosis, but have now met with a few in which such a prognosis was not justified. About five years ago I removed a cancerous tumour of the sigmoid, together with several enlarged glands in the attached portion of the mesentery. The glands were as large as filberts, and I thought the case quite hopeless; nevertheless she is still in excellent health, and continuing her vocation as a domestic nurse.

Nearly three years ago I removed the cæcum and lower part of the ileum from a gentleman, æt. 37, for a soft malignant growth. The lump was the size of a fist, and several glands were enlarged, one measuring an inch and a half in diameter. Here, again, I gave a bad prognosis. He recovered well from the operation, and a year later was in such excellent health that his medical friend, Dr. Heatherley, refused to countenance any longer a pessimistic outlook. He came to me and said, in effect—"Look here, you must do something for this fellow. He must not be condemned to die in this sort of way. How about X-rays?" Well, I do not think we have at present any information which warrants us to suppose that X-rays would influence the course of such a case, so I suggested that if the patient was willing to lay up for a month I would explore the abdomen, ascertain what the present condition was, and do what seemed to be best in his interests. This was decided on; and one day, after quite half an hour's exploration, I succeeded in discovering and extracting one small gland the size of a split pea, which on microscopical examination showed no malignant change. Another year and a half passed and the patient is still as well as ever—so well, in fact, that he at once agreed to come here with Dr. Heatherley to show us that we

know almost as little about the prognosis as about the treatment of cancer. (a)

## ON THE NECESSITY FOR SCHOOL HYGIENE. (b)

By J. C. McWALTER, M.A., M.D., D.P.H. Dub.

THE sense of parental responsibility has been greatly lessened by the operations of a Compulsory Education Act, and now the public look to educational authorities for that training of the child, both mental and physical, which may fit it to be a good citizen. The need for some knowledge of reading and writing is surely not more pressing than the necessity for the development of a vigorous and healthy frame, for sound teeth, for well-developed muscles, for keen eyes, for steady nerves. As all these can be obtained or improved by intelligent training, an obligation rests with the local authorities to supply not only competent instruction in literary or technical subjects, but skilled advice available for the proper physical development and examination of the pupils.

Not only does compulsory education demand the possession of the child for half the day, but it monopolises it for all the period during which the parent might otherwise obtain expert advice regarding its teeth, its eyes, its nose, its throat, its chest, its spine, &c., and thus the parents can scarcely be blamed if they neglect these matters and allow the children to grow up comparatively deteriorated specimens of humanity.

The comparative ease and cheapness with which the examinations of a medical attendant can be effected in a school should be a sound economic argument for their more universal adoption. It is possible to get the services of an ophthalmic surgeon of considerable skill to overhaul the eyesight of every scholar in a school of a couple of hundred in a comparatively short time, and for a moderate fee, although the services of such a specialist would normally be outside the powers of the family of any one of the scholars. Skilled rhinologists are available to detect the various abnormalities of the naso-pharynx, and so save a lifetime's discomfort to many a child. The numerous osseous abnormalities which deform so many of our young scholars are notoriously easy of rectification or prevention where the skill of an orthopædic surgeon or of a scientific instructor of gymnastics is utilised.

A cry has gone forth from almost every doctor in the kingdom calling on the Government to provide for the regular scientific teaching of young scholars in the principles of temperance and hygiene, and thus the foundation of healthier and happier homes must be laid. The Socratic principle, that vice is due to ignorance, and not to innate depravity, is becoming recognised as the proper guiding rule for the State when it takes on itself the training of children, and this principle is perhaps even more potent when dealing with physiological than with psychological sins. Habits of hygiene, acquired in the school days, are obviously of much more influence than spasmodic efforts to attain sanatorial righteousness when attempted in later life.

The researches of Dr. Kerr seem to incontrovertibly prove that a grave deterioration occurs in the health of children whilst at school, for which the system of education is responsible. Thus he found that whilst about 10 per cent. of school children had various defects of vision, only about 3 per cent. were abnormal on entry. It was proved that the vision of 7 per cent. of school children had become affected by some circumstances of their training—circumstances which should be avoidable and preventable under an enlightened scheme of examination by competent medical officers.

(a) Dr. Heatherley tells me that this summer he made fifty runs in a cricket match—not a bad performance for a man without a cæcum.

(b) A Paper read at the Folkestone Congress of the Royal Institute of Public Health, July 21st, 1904.

It is well known that scarlet fever, measles, whooping-cough, mumps, phthisis, and such ailments as ring-worm, ophthalmia, and itch ensue on the aggregation of children at the most susceptible ages in ill-lighted, ill-ventilated, and often dirty school-rooms. The deaths from measles occur almost entirely under the age of five years, and in nine cases out of ten epidemics may be traced to the infant departments of schools. Seventy per cent. of scarlet fever cases are stated to occur among children who would attend such schools. In some districts, 25 per cent. of the cases of diphtheria are between the ages of three and five, and nearly all the cases of whooping-cough occur in children attending school. Regarding phthisis, statistics are less exact, but there is little doubt that numerous deaths, classed as due to convulsions, typhoid fever, brain fever, and the like, are really cases of tuberculous meningitis, contracted in school-rooms, whilst the larger part of deaths classified as due to bronchitis, under the age of ten, are really examples of broncho-pneumonia of a tuberculous origin, and the *fons et origo mali* is a source of infection in the school-room.

In his Harben Lectures given this year, Dr. Hueppe asserts that the three factors which give rise to consumption are predisposition, stimulus, and condition. Now in our schools children come together from all kinds of homes—from the most depraved and filthy to the more highly respectable. Some of them are half starved, and some not physically fit to acquire any knowledge. Where such a crowd of children is huddled together, there is a slow undermining of health from the want of fresh air, which soon establishes a favourable condition for the development of phthisis; the predisposition is only too often in the family, and the immediate stimulus is fairly sure to be brought in unless the children are periodically inspected and the more delicate ones removed. When an inspection can be made at the beginning of every term, every child in the room should be examined by a medical officer, and those suffering not only from infectious disease, but from itch, ringworm, vermin, &c., those apparently unfit to receive instruction through delicacy, or those in any doubtful condition, could then be sent home and not readmitted until they produced a certificate from their own doctor that they were fit to resume. The problem of excluding phthisical children is a grave one, but is best dealt with by a *periodical weighing* of all the children, which can easily be done by an intelligent teacher under the direction of the medical officer. If a periodical progression, according to a given scale, be not observed, the child must be subjected to further examination.

Then open-air instruction ought to be availed of far more freely than at present. Nothing is more notorious than that phthisis and other communicable diseases prevail to an enormous extent in many parts of the country where all the natural advantages make for the most perfect health; but the healthiness of dwellings and schools is often in the inverse ratio to the salubrity of a locality. The worst examples of sanitation in schools and rooms is found in the best parts of the country. I am constantly shocked by the number of cases of phthisis which I find in a seaside village which ought to be a health resort; even a few home industries there appear to be mere foci for infection. The morbid horror which certain country people exhibit for air or light in their bedrooms, and their contemptuous disregard for sanitation, are of course the cause. If the teacher of the village school was compelled to conduct his operations in the open air, where practicable, his health and that of his charges would alike benefit.

A valuable means of detecting the incipient signs of ill-health is obviously the weighing-machine. No teacher can be expected to exhibit such proficiency as to enable him to detect diphtheria or adenoids or astigmatism, but every school superintendent is competent to take the weight of his pupils periodically, and to see if they answer to a certain scale. It is, of course, well ascertained that no surer sign of disease exists than insufficient increase in the weight of a

growing child, and there is always a proportionate increase when every function is normal. Children who fall below their average can easily be brought under the notice of the medical attendant and subjected to a more thorough examination.

Again, the age at which the child must be sent to school ought to be not five but six years, and no infant under five should be accepted. It is thoroughly proved that children who start schooling at six or seven years rapidly overtake those who commenced at four or five, and to admit infants of such a tender age is merely a concession to the laziness of the parents who seek to get rid of them for five hours a day.

Dr. Martin, of Gloucester, sagely suggests that cases where it is sought to exclude children from school because of their generally dirty or verminous condition should be treated by graduated pressure. First he suggests that an informal notice should be sent the parents, apprising them of the facts, and if this did not avail a formal intimation that the child would be excluded until the trouble was remedied.

When one speaks of a systematic examination of a school the question of cost at once jumps into prominence. Dr. Martin proposes to give the medical officer a guinea for a complete examination of a school of from 50 to 100 pupils, and two guineas where the number goes up to 300. As such a complete examination need not take place oftener than once a term, its cost is not prohibitive. In his district the average attendance is 87.5 per cent., and he calculates that a gain of 2 per cent. resulted from the periodical medical examination of the scholars, which meant in that county £1,600 a year.

Habits of cleanliness are of far more educational value to the children who attend our elementary schools than most of what they are taught to learn. It should, therefore, be strenuously insisted on that every school be provided with an adequate lavatory. To have, as is so often the case, a couple of towels for a hundred pupils is, of course, to propagate disease and uncleanly ideas.

The Royal Commission on Physical Training has already recommended that provision should be made for the regular medical examination of school children; but a practical and complete scheme for inspection is still wanting, and it should be the function of a body so representative of every school and class of sanitarians as the Royal Institute of Public Health to supply it. Many authorities consider that a child should be thoroughly overhauled at least three times during its school life, but, on the other hand, the cost of such a scheme would be very high, as it is calculated that the whole time of a medical officer of health would be taken up examining the school children of a town of 100,000 (say with 16,000 school children). But obviously, a Congress such as this will lead to the better informing of public opinion, when the cost will no longer be regarded as unprofitable.

## LARGE FIBRO-CYSTIC TUMOUR OF THE UTERUS

(WEIGHT 28½ LBS.).

REMOVED BY ABDOMINAL HYSTERECTOMY; FOLLOWED BY GANGRENE OF THE RIGHT LEG. (a)

By FRED. BOWREMAN JESSETT, F.R.C.S.,  
Surgeon to the Cancer Hospital, Brompton, &c.

E. G., æt. 54, married 33 years, five children, youngest æt. 22; has not, so far as she can perceive, reached menopause.

Six years ago an exploratory operation was performed at a London hospital for "flooding and tumour." According to the report from the surgical registrar, "a large uterine fibroid was found. Nothing further was done." Soon after leaving the hospital she had two floodings, more since. Now, the abdomen gets very big, no pain, but patient is unable to get about properly.

(a) Paper read at the British Gynaecological Society, July 14th 1904.

Varicose veins in legs for last three years, and occasional ulcers. General health fair, but is losing flesh. Constipated; menstruation regular every four weeks, lasting about a week; loss slight.

*On Admission.*—Florid, but thin. Abdomen enormously distended, umbilicus flattened, old median scar below it. Large mass occupying practically whole abdomen, dull on percussion, no thrill, not tender. Superficial veins distended.

*Per Vaginem.*—Uterus low down and cervix directed to right. Mass felt through posterior fornix.

She was admitted into the Cancer Hospital on Wednesday, June 1st, and on the 7th Mr. Jessett operated: An opening about three inches in length was made in the middle line below the umbilicus for exploration. The tumour was found to be firmly adherent to the parietes, but by using some considerable force the parietes could be peeled off. The whole scar tissue was removed by an elliptical incision, and the abdominal incision enlarged to enable the hand to pass round the tumour, when it was found to be quite free behind and the intestines well pushed up and not adherent. Mr. Jessett then, by bringing his hand up from behind, was enabled to peel the parietes quite free from the tumour, which was then readily shelled out, not, however, until the parietal incision had been prolonged from the pubes quite to the ensiform cartilage. The omentum was adherent to the tumour and had some very large veins. This was ligatured in segments and cut across. The broad ligaments were then tied and divided; the uterine arteries secured, and the cervix uteri cut across, after having stripped down an anterior and posterior flap of peritoneum. There was a considerable amount of oozing, so Mr. Jessett packed the cavity with iodoform gauze and brought the end out of the lower angle of the parietal wound.

The patient suffered a good deal from shock during the operation and after the removal of the tumour, which weighed 28½ lbs.; so Mr. Keyser injected four pints of saline fluid into the median basilic vein, and a subcutaneous injection of strychnine was also given. After stitching up the peritoneum, two pints of saline fluid were introduced into the peritoneal cavity before finally closing the parietal wound.

The patient was returned to bed and seemed as well as could be expected. She, however, complained of a good deal of pain in her right leg, which was somewhat dusky and cold. This was wrapped in cotton-wool and flannel bandages. Had a fairly good night, but showing signs of some collapse, two pints more saline fluid were given by the arm, and small quantities of saline fluid and brandy and beef-tea administered by the rectum.

*June 8th.*—Pulse small, but good; temperature normal. No distension; gauze drainage removed. No sickness or vomiting. Ordered brandy, milk, and lime water by the mouth, which she retained. General aspect fairly good. Leg still somewhat discoloured but warm. Not so painful. Rectal feeding continued.

The patient gradually improved from day to day, the abdomen keeping quite flaccid. Bowels opened, kidneys acting well, and she takes plenty of nourishment.

*June 13th.*—Patient expresses herself better and stronger, takes all nourishment. The leg, however, is quite gangrenous from the knee downwards, being discoloured and cold, due undoubtedly to impeded blood supply, the skin being dry and shrivelled. No sensation below the knee. There are a few blebs. The limb is kept wrapped in boric lint, dusted with boric acid powder and the whole enclosed in a quantity of cotton wool.

The line of demarcation is just above the patella, tending downwards and backwards to about two inches below the joint posteriorly. The patient continued to improve daily, and on June 21st, fourteen days after the operation, with the assistance of Mr. Churchill, I amputated the leg at the junction of the upper and middle third of the thigh. She bore the operation remarkably well, and suffered very little from shock.

Before the operation she had a nutritive enema of brandy ʒj, beef-tea ʒij, administered.

*June 22nd.*—Has passed a good night and taken a small amount of nourishment. She has also been sustained by nutritive enemata. Ordered beef-tea, egg and brandy, milk and champagne.

*June 23rd.*—Stump dressed, a good deal of oozing from the drainage-tubes; stump looks well. Patient's condition generally satisfactory. Pulse good quality, but very quick. Temperature normal.

Patient gradually lost ground and died on Sunday, the 25th, four days after the amputation, and nearly three weeks after the removal of the tumour.

*Post-Mortem.*—The abdominal wound was quite healed and firm. There was some suppuration in the stump. The external iliac was found to have a firm clot in it extending from its junction with the common iliac for about one inch downwards.

The kidneys were both much diseased and degenerated; this was not suspected, as the urine was tested before the first operation, and only showed very slight traces of albumin; possibly the pressure of the tumour may have had something to do with this.

This case is of interest on account of the size of the tumour and also in respect to the gangrene of the leg. That this was caused by the plugging of the external iliac there can be no doubt, but it is difficult to understand why this artery was plugged as there was no sign of its being involved in the ligature or twisted. Could it have been caused by the pressure of the tumour? But, even then, why was not collateral circulation established? It has been suggested that these clots may be the result of bacterial infection. In this case it could hardly have been so, as the patient complained of pain, and the leg was somewhat dusky within an hour of the completion of the operation.

## DETACHMENT OF THE CHOROID.

By ROBERT DWYER JOYCE, F.R.C.S., &c., &c.,  
Ophthalmic and Aural Surgeon to the Richmond Hospital, Dublin,  
and St. Michael's Hospital, Kingstown.

A LADY, æt. 59, consulted me recently for blindness of her right eye.

The patient is healthy, no cardiac or renal trouble; she suffers, however, frequently from constipation. There is no history of a blow or injury of any sort to the eye, nor was it ever inflamed more than the ordinary redness from a cold; but the patient fell—not very violently apparently—on the back of her head about eighteen months ago. Patient says quite distinctly that her right eye was always better than the left for distance as well as for near work (she used to shut the left when threading a needle, &c.), but one evening, about three months ago, she discovered that it (R.) was blind. She was greatly frightened. Her sister at once took her in hand, and poulticed the eye with bread and water continuously for a whole day and night; without avail, however, as she did not succeed in making a cure. Patient wears —1.25 sph. glasses, both eyes, for distant vision.

Present condition:—R. eye: vision = 0 (when full sunlight was reflected into the eye she said she "thought she saw something").

L. eye: vision =  $\frac{6}{20}$  >  $\frac{5}{20}$  with — 1.5 sph. C — 0.25 cyl. ax. hoz. R. eye is quite normal superficially, but the pupil, 4 mm. in medium light, was larger than the other. With the ophthalmoscope (direct method, i.e., without any intermediate lens) retinal vessels can be seen when viewed from a distance of about ten inches from the eye. With the indirect method, the whole fundus is seen to be occupied by two large bulging abrupt prominences, separated

from one another by a very deep furrow, nearly vertical, but slightly inclined towards the nasal side, above. From the position of this furrow the optic nerve head would be situated in it, but it was not visible. The two large prominences were almost the colour of the ordinary normal fundus, but were slightly more yellow, and gave, in places, the idea of translucency. They were covered by the retina, the vessels of which were perhaps a little darker than normal. Besides these, however, the close characteristic network of the choroidal vessels could be seen without difficulty over the upper and also over the inner part of the nasal prominence, and they were situated in the same plane as the retinal vessels. I was unable to see any trace of choroidal vessels elsewhere. No undulatory movements of the prominences were visible when the eye moved, like those seen in simple detachment of the retina.

The tension was down (-1). I could detect no disease of any visible part of the retina, but the walls of the retinal vessels were thickened. The anatomical condition in this case is evidently large detachment of the retina corresponding to the two prominences, with two small detachments of the choroid, situated at the places where the choroidal vessels were visible.

Detachment of the choroid, following extensive loss of vitreous, or injury, is not very uncommon, but pure idiopathic cases, like the above, are among the very rarest diseases of the eye.

### Transactions of Societies.

#### BRITISH GYNÆCOLOGICAL SOCIETY.

MEETING HELD THURSDAY, JULY 14TH, 1904.

DR. H. MACNAUGHTON-JONES, Vice-President, in the Chair.

MR. CHRISTOPHER MARTIN exhibited the following specimens—(1) Bone crochet hook removed from the abdominal cavity; (2) and (3) Two specimens of Arrested Development of the Uterus; and read the following notes:—

1. My first specimen is a foreign body which I removed from the abdominal cavity in December last. It is a portion of a bone crochet hook about five inches long. The patient was a widow, æt. 48. She had missed her periods for a few months, and believed she was pregnant. With the object of procuring abortion she got a bone crochet hook, and having sharpened it to a point, pushed it up into the uterus. It slipped from her fingers and she was afterwards unable to get hold of the end of it. It worked its way right through the uterus and became free in the peritoneal cavity. She became alarmed, and consulted her own medical man, who sent her to me, and when I examined her a fortnight after the occurrence, I could feel the foreign body lying in the left iliac fossa quite apart from the uterus. She was a very thin woman, so that it was quite easy to palpate it. She was not pregnant. I opened her abdomen and found this bony rod lying in the left iliac fossa, completely embedded in the omentum. It was easily removed, and she made a good recovery from the operation. On looking at the uterus I could see on the posterior aspect, just above the level of the internal os, a round, depressed scar—evidently the spot through which the rod had passed. There were a few adhesions between the omentum and the small intestine, but there were no signs of inflammation in or around the uterus itself. When I saw her she was in a very strange mental condition bordering on insanity. She was firmly convinced that she was pregnant and that she would still have to be confined, and would have to go to prison for attempting to procure abortion. I saw her again about two months ago, and then found

that she had developed cancer in the breast, which, however, she refused to have removed.

2. The next specimen illustrates one variety of arrested development of the uterus. The patient was a single girl, æt. 18, who had never menstruated. About the age of fifteen the usual external signs of puberty appeared, and she began to have monthly attacks of pain in the pelvis, lasting for a few days. These monthly pains gradually increased in severity until she saw me. When I examined her I found her a well-developed girl as regards figure and mammae. The vulva was normal, but there was no vagina except a small cul-de-sac about half an inch deep. On passing the sound into the bladder, and finger into the rectum, it was evident that nothing intervened except the vesical and rectal walls. I opened her abdomen and found that the uterus was represented by two small solid muscular bodies, one on each side of the pelvis. Each of these bodies received at the upper end a small Fallopian tube and a well-marked round ligament. Below, each body faded away in the cellular tissue between the bladder and the rectum. The right body was better developed than the left. The ovaries were well developed and apparently normal. There was no structural connection between the uterine body of one side with that of the other; they were, indeed, separated by a gap of two inches. As I was anxious to stop the monthly paroxysms of pain, I removed both the ovaries, together with the Fallopian tubes and the representatives of the uterus. The patient made a good recovery; she has since remained well and is quite relieved of her old pains. It is evident that in her case the two ducts of Müller did not coalesce, whilst the uterine and vaginal portions were arrested in their development and did not form mucous canals. A week or two ago the patient came again to see me, looking very well, and she informed me that she was thinking of getting married, and was anxious to know if I could make her a vagina.

3. The third case is one in which the uterus was bicornuous—the right horn being distended with menstrual fluid and not communicating with the rest of the uterine cavity. The patient was a single girl, æt. 21, anæmic and delicate, who consulted me on June 1st, 1904, complaining of violent pain in the right lower abdomen at each period, lasting the whole of the time and continuing some days afterwards. Menstruation occurred every three weeks, was scanty and only lasted three days. On examining her I found a mass about the size of an orange, in front of and to the right of the uterus—a mass which I took to be tubal or ovarian. I took her into the hospital and on June 18th I opened her abdomen. I found the mass to be the right horn of a bifid uterus. It was tense and globular, and evidently contained fluid. It was separated from the rest of the uterus by a bridge of fibrous and muscular tissue. The distended right horn, right tube and ovary were very adherent. I removed them by dividing this bridge and was able to save the rest of the uterus with the left ovary and tube. The patient made a good recovery and returned home on July 10th.

Dr. HEYWOOD SMITH said that it was remarkable how often sounds or other instruments passed through the uterine wall without setting up any mischief. One lady he knew had brought on her own miscarriage thirty-five times, and on several occasions nearly lost her life from severe flooding; she used a long knitting needle for the purpose. Malformation or displacement of the kidney was so often associated with arrested development of the uterus that he would like to know whether Mr. Martin had examined the position of the kidneys.

Mr. BOWREMAN JESSETT suggested that the last specimen might possibly be a fibroid or myoma of the Fallopian tube; it did not, in his opinion, resemble a bicornual uterus.

Dr. ROBERT BELL (Glasgow) mentioned a case he operated upon for a tumour which he took to be a subserous fibroid of the uterus or possibly, as its attachment was at the cornu, of the Fallopian tube, and he removed it under that impression. The woman had been pregnant two years previously, and the pregnancy

had terminated suddenly, a fact which he did not ascertain till after the operation. On a section being made of the tumour it was found to contain a four and a half months fetus in perfect preservation. The tumour weighed four pounds and had all the appearances of a fibroid.

Dr. H. MACNAUGHTON-JONES (Chairman) said that it was remarkable what a variety of instruments could be used to procure abortion; he had known the handle of a toothbrush successfully employed for the purpose. One of the unpleasant consequences which might follow such attempts was that imputations quite unfounded might be cast on the ordinary medical attendant. In a uterus examined by Mr. Bland-Sutton and himself there was a perforation, and a portion of cotton wool was found in the abdominal cavity. The woman had been attended by a midwife, but the consequence to her ordinary medical man was very disastrous. Mr. Martin's second case was of much interest; among five cases of total absence of the uterus and ovaries he (Dr. Macnaughton-Jones) had himself published, two were in children and in one of them he had succeeded in making a very fair artificial vagina; in the other, particulars of which he had read to the Society at a former meeting, the abdomen was opened for inflammation of the appendix, which was bound down to the floor of the pelvis. Before the operation he had been able by a vesico-rectal examination to determine the absence of the uterus and ovaries. He might refer to one of the three other adult cases as it had a bearing upon the question of making an artificial vagina, as von Ott and others were reported to have done successfully. In his own case he had not been able to make a good vagina and a rectal fistula was left. He was able to close the latter successfully, but had to sacrifice the substitute for the vagina he had made. Before the operation the mental condition of the patient was such as to cause grave anxiety; she had become hysterical and almost delusional, and was greatly reduced in strength; after the plastic operation her health improved greatly and she became, and has remained, robust and well. It therefore seemed that the production of even a small artificial vagina might have a good effect. He was not sure that Mr. Martin's third specimen was a uterus, and suggested that it should be examined by a pathologist.

Mr. MARTIN, in reply, said that there was nothing to lead him to suppose anything anomalous about the kidneys, and examination of their position would have involved a larger incision than he cared to make. A section had now been made of the third specimen and the centre evidently consisted of inspissated blood-clot, which, he held, supported his view that it was the occluded horn of a bicorned uterus filled with retained menstrual blood. The specimen had been hardened by formalin, but when removed the tumour was quite flaccid. Dr. Macnaughton-Jones had referred to the medico-legal aspect of the first case. If it had proved fatal, it might have been his duty to decline to certify. It was remarkable how little trouble the very sharp piece of bone had caused; perhaps it had been cleansed of any infectious germs in its passage through the muscular wall of the uterus, but the mental state of the woman might partially account for her immunity. Insane women were curiously tolerant of abdominal injuries, and in many instances had opened their own abdomens and yet recovered without any bad symptoms from conditions that, in all probability, would have led to fatal peritonitis in others. He was convinced that the third specimen was an occluded horn with retained menstrual blood, but he would be pleased to have it examined by a pathologist, as suggested, and would submit a report to the Society.

Mr. BOWREMAN JESSETT reported upon a case of  
GANGRENE OF THE LEG AFTER ABDOMINAL  
HYSTERECTOMY

for the removal of a large fibro-cystic tumour, and showed the tumour removed. Notes of this case will be found on page 85.

Mr. JESSETT also showed a  
MYOMATOUS UTERUS, REMOVED BY ABDOMINAL  
HYSTERECTOMY,

illustrating the presence of sub-mucous, interstitial and sub-peritoneal growths, and read the following note:—

A. H., æt. 50, married, no children or miscarriages, was seen by me in consultation with Dr. Smyth, Colebrook Road, on June 2nd, 1904. *History:* For about two years has had aching pains in the groins, especially the left, and in the back. Of late has noticed a swelling in her abdomen. Has had a brownish discharge for last six months. Complains of morning sickness, nausea, and pains in the upper abdomen after meals. No hæmatemesis; no increase in micturition; menstruation regular monthly, lasting a week, less copious, with pain for one or two days.

*Examination.*—The abdomen is distended at the lower part by a large, very hard mass, extending to within one inch of the umbilicus, and not mobile; no tenderness; a hard knob is felt in the right side, mobile. Rest of tumour smooth, and apparently wedged into the pelvis. *Per Vaginam:* Cervix high up and to the left. Body of uterus not distinguishable. Mass, filling both fornices, continuous with abdominal tumour. On bimanual examination, the tissue is very fixed, only very slightly mobile. On June 14th, I opened the abdomen by the usual incision, and, by means of a Doyen hysterectomy screw, with some difficulty lifted the tumour out of the abdomen, and removed it by the sub-peritoneal method. The patient made an uninterrupted recovery. On section of tumour it was found to contain several large sub-mucous, intramural and sub-peritoneal fibroids.

Mr. CHARLES RYALL said that Mr. Jessett was to be thanked for showing the giant myoma again, and for the further history of the case, especially as it had turned out unsuccessfully, for much more was generally to be learned from one failure than from many successes. Apart from the immense size of the tumour, the remarkable point was the extent and extreme intimacy of its adhesions to the abdominal wall. The cause of the gangrene was very obscure; the early onset of the symptoms contradicted the idea that it was due to bacterial invasion at the time of the operation. He thought that the gangrene might possibly be due to thrombosis of the common iliac extending down to the bifurcation and then along the external iliac, or to dislodgment of an embolus in the aorta, owing to the manipulation of the tumour at the time of the operation.

Dr. HEYWOOD SMITH mentioned that many years ago a patient of his did perfectly well after hysterectomy for nearly a fortnight after the operation, and then fell back dead while sitting up to have her dinner, the cause of her death being a pulmonary embolus. In that case the tumour had been a very large one. The occurrence of embolism after abdominal operation was a question of deep interest. Possibly it was more frequent in connection with large tumours where the blood supply was very large, and the vessels subjected to pressure, and perhaps to tension, at the time of the operation.

Dr. J. J. MACAN reminded the Fellows that though gangrene was uncommon, if not unique, after abdominal operations, it was by no means so after childbirth, affecting various parts of the body, but most commonly the lower extremities. In a recent number of the *Centralblatt* there were abstracts of articles on the subject by Schaeffer and Wormser, and both of them agreed in attributing it to infection. In Mr. Jessett's case it seemed that infection, if it had any influence, must have existed before the first operation.

Dr. RICHARD SMITH asked whether there had been any œdema of the leg, and what had been the after treatment.

Dr. MACNAUGHTON-JONES, jun., suggested that the pain complained of by the patient two hours after the operation could hardly have been due merely to local œmæmia, and that there might have been some pressure on the nerve as well as on the artery.

Dr. ROBERT BELL remarked that in a blood-vessel, so far as he understood it, coagulation could only occur

in the presence of a foreign body. In healthy blood-vessels coagulation would not take place, but inflammation in a vein or artery would act as a foreign body, and would produce the catalytic effect which caused the formation of a clot. In a case such as the one Mr. Jessett had brought before them, some injury might have occurred to either the innominate vein or artery, but if to the former the embolism would have been in the pulmonary artery rather than in the iliac, and he therefore thought that there must have been some lesion of the iliac artery to account for the clot.

Mrs. SCHARLIEB mentioned a case in which arrangements had been made to remove a very large fibroid, but two days before the proposed operation the patient was taken exceedingly ill with thrombosis of the left femoral vein, and the operation had to be postponed *sine die*. The patient had not suspected any phlebitis or other trouble in her leg, and there had not been any recent operation or manipulation in her case.

Dr. BELL explained that he by no means suggested that Mr. Jessett had injured the artery. Mrs. Scharlieb's case supported his own theory that the pressure of a large fibroid upon the iliac vessels might cause sufficient irritation to cause the formation of a clot, and thus produce the same effect as a foreign body.

Dr. MACNAUGHTON-JONES said that he did not conclude that there had been any injury to the iliac artery during the removal of the tumour. Large tumours pressing upon the great vessels of the pelvis undoubtedly sometimes affected these vessels injuriously, and it was more than possible that in the present case, especially considering the co-existent kidney disease, there had been an obstructive arteritis and that the manipulation necessary during the operation had loosened a clot already formed. He had himself shown pelvic tumours after the removal of which there had been œdema of the leg, inability to walk and other troubles.

Mr. JESSETT, in reply, said that there had not been before the operation any swelling of the legs, such as would naturally have been attributed to pressure of the tumour. The patient, it was true, had varicose veins, but not to any extent worth noticing. Pressure sufficient to interfere with the arterial circulation must, he thought, have interfered with the venous also, and would then have caused considerable swelling of the legs. Although the clot in the external iliac extended about an inch up to the bifurcation, the internal iliac was free, and it was difficult to understand why the collateral circulation was not sufficient to carry on the nutrition of the limb. In his opinion, the only explanation of that was that during the operation, perhaps owing to nervous shock, the woman lost very little blood, the general circulation was impeded, and the *vis a tergo* was insufficient to drive the blood through the leg, and a clot gradually formed which increased the difficulty. It had also crossed his mind whether the saline solution, of which the patient received a considerable quantity, had been absolutely sterile. There was no moisture in the gangrene whatever, the leg was simply dried up for want of nourishment. Dr. Macnaughton-Jones, jun., had suggested that there had been pressure on the nerve as well as on the blood-vessels to account for the pain. It was possible; we were all familiar with the sensation of "pins and needles" which supervened on the removal of pressure. Still in his own opinion, the arrest of the blood supply was the cause of the pain from the commencement.

Dr. HEYWOOD SMITH (Vice-President), having taken the chair,

Dr. MACNAUGHTON-JONES read a paper on ACCESSORY FALLOPIAN TUBES AND THEIR RELATION TO BROAD LIGAMENT CYSTS AND HYDROSALPINX, and showed some specimens illustrative of the origin of hydrosalpinx from accessory Fallopian tubes. Sampson Handley had criticised Kossmann's view that broad ligament cysts are neither parovarian nor cystic dilatations of the Wolffian diverticula or ducts, but are derived from accessory Müllerian ducts (sacroparasalpinx serosa). Handley and Shattock

had demonstrated from specimens in the College of Surgeons Museum the origin of accessory hydrosalpinx from the pronephric funnels of the Müllerian duct. Handley also showed that enucleable broad ligament cysts, developed above the tube, were derivable from accessory Fallopian tubes. Alban Doran had anticipated Kossmann in his surmise that such cysts were of Müllerian origin. Hamilton Bell, from the examination of a cyst removed by Cullingworth, supported Handley's contention. The histological analogy between the accessory and the ordinary hydrosalpinx was complete.

These histological analogies were typically shown in the first of Dr. Macnaughton-Jones' specimens. The cysts were derived from the Fallopian tube. The ovarian fimbria was absent, and its place was taken by two cysts.

The second specimen Dr. Handley reported to be undoubtedly an accessory Fallopian tube, the important point in this instance being that both the pedicle of the cyst and its wall were muscular, and the cyst was lined with ciliated and columnar epithelium.

The third specimen was very interesting, and though not microscopically examined, there was little doubt of the nature of the cysts. When one of these was held up against a strong light, the plicæ could be seen through its wall. In this instance there was a cyst in the free edge of the broad ligament, attached to which were two small flattened cysts, while hanging from the peritoneal folds there were two small cysts and an accessory Fallopian tube. These latter, Dr. Handley considers, represent in abnormal number the pronephric funnels. He also showed with the epidiascope other specimens illustrating the paper.

He exhibited a form of clip to which a small weight was attached by aluminium bronze wire, intended to supersede the use of forceps in keeping the cut edges of the peritoneum in position after opening the abdomen.

Dr. HEYWOOD SMITH said the only criticism he would offer of the cases described by Dr. Macnaughton-Jones was as to the word accessory. When speaking of accessory organs one had in mind an organ parallel in function to the one described, such as an accessory mamma or accessory kidney. He suggested that in the case mentioned by Dr. Macnaughton-Jones the word diverticulum or aneurysm of the duct should be used. They were really excrescences which seemed to be cut off, but evidently had the same foundation as the tube itself.

Dr. MACNAUGHTON-JONES said he could not agree with Dr. Heywood Smith in his criticism.

Dr. JERVOIS AARONS showed

#### A NEW UTERINE MOP,

reading the following note:—The difficulty and length of time wasted in removing the wool from the ordinary Playfair's probe after it has been used led me to try and devise some means by which the mop might be more easily and quickly removed. It occurred to me that a cap of some absorbent material which would fit over a conical sound would serve the purpose, and such a cap, or mop, I have had made; this slips over a conical or tapering metal sound, and is held in position by a small ring catch, which effectually prevents it from leaving the sound. The dry mops weigh 13 grains ('79 grammes); after being used they weighed 39 grains (2'5 grammes); they are, therefore, sufficiently absorbent for the purpose. The advantages over the ordinary Playfair's probe are: (1) Ease and rapidity of dressing the probe; (2) ease and rapidity of removing the mop after use; (3) they are easily sterilised; (4) the tapered part of the sound being made of plated copper can be bent to any desired shape. The caps and the probe were made for me by the Galen Manufacturing Co., Ltd., and I am indebted to them for the way in which they have carried out my ideas.

Dr. HEYWOOD SMITH concurred as to the difficulty in getting the cotton wool off the Playfair probe, unless one had the knack of rotating it in a direction contrary to that adopted when putting it on. The

present device was useful because the ring got on in its place.

#### THE SOCIETY FOR THE STUDY OF DISEASE IN CHILDREN.

THE Provincial Meeting took place at Bristol on June 18th, Dr. THEODORE FISHER in the Chair. Prior to the meeting clinical cases were shown at the Hospital for Sick Children, St. Michael's Hill, and at the Medical Library, University College.

Dr. D. S. GERRISH showed some remarkable examples of "Progressive Muscular Atrophy" of the family type. He had been able to trace the disease back through five generations, and over forty members of the family had been affected. The usual history was that up to the age of 23 years the patients had been remarkable for their physique and muscular strength, but after that age the extensor muscles of the leg began to waste, chiefly the anterior tibials and the peronei. The condition slowly and steadily increased, and by the fiftieth year it had extended to the extensor muscles of the arms. Sensation had never been affected, but the reaction of degeneration was present. Although their hands were affected the patients retained their grip, but extension became very weak.

Dr. BERTRAM H. ROGERS read notes of a case of "Congenital Stricture of the Oesophagus." An infant, *æt.* about 2, began to suffer from vomiting, the condition getting rapidly worse, and being accompanied by emaciation. No definite physical signs of disease were present save much mucus in the lungs, and over-distension of the cervical veins on crying. Test meals showed that most of the food entered the stomach, but part seemed to be retained in the oesophagus. The use of X-rays and an oesophageal tube threw little light on the nature of the case. The child died from an increase of the bronchial trouble and dyspnoea. At the necropsy there was found a fairly tight stricture about an inch from the lower end of the oesophagus.

Mr. H. ELWIN HARRIS showed three cases—(1) "Congenital Absence of the Left Ear with Facial Paralysis"; (2) "Congenital Absence of the Left Eye with Cleft Palate and Hare-lip"; and (3) "Intra-uterine Amputation of Three Extremities, with Webbed Fingers on the Hand of the only Limb." The last case was a very remarkable one, as both legs were absent from 1½ inches below the hip-joint, and the left arm was removed flush with the shoulder-joint. On the stump of the right lower extremity was a very minute leg in which one could trace a rudimentary knee-joint, ankle, and foot. He did not know any satisfactory explanation of such deformities, and did not think that the theory as to amniotic adhesions was conclusive.

Mr. CLEMENT LUCAS expressed his disbelief in the theories current as to intra-uterine malformations such as maternal impressions, amputation by the funis, &c. He thought that if any satisfactory theory could be formed it would be one in which the nervous system played an important part.

Mr. GEORGE PERNET thought that such a theory as that of maternal impressions was a nuisance to science, and should no longer be tolerated.

Dr. J. MICHELL CLARKE showed a case of "Hydrocephalus" in which recovery had occurred. The illness probably began at the age of six months, and the patient had been under observation for some years. Intelligence had never been affected, but there had been marked weakness of the muscles of the trunk and lower extremities. After three years improvement set in, and the only traces of disease visible were the large size of the head and some signs of partial degeneration of the pyramidal tracts. The treatment had been by small doses of grey powder, continued over long periods.

Mr. C. A. MORTON read the notes of a case of HYDROCEPHALUS IN WHICH DRAINAGE OF THE VENTRICLES into the subdural space was established. The method of operation was that introduced by Mr. Watson

Cheyne, in which a communication is established between the distended ventricle and the subdural space, so that the fluid may be readily absorbed by the meningeal veins. The patient was an infant, *æt.* 7 months, suffering from congenital hydrocephalus. The first operation consisted in turning down a flap on the right side of the skull below the anterior fontanelle, and introducing a piece of fine rubber tubing, one end of which was passed into the ventricle and the other between the dura mater and the cortex. The flap of dura mater and membranous skull was then replaced and stitched carefully, so that all oozing had ceased at the end of twenty-four hours. On the eleventh day after the operation the head, which had been much smaller as the result of the operation, again showed signs of enlarging. A few months later the operation was repeated on the opposite side, the head still increasing in size. A small rectangular metal tube was first employed, but as the fluid would not flow through it, a rubber tube was inserted. Some leakage from the operation wound continued for a few days, and the cranial bones were over-riding. The temperature ran up to 105° on the evening of the tenth day, and the baby died. At the necropsy the brain was found to be lying about an inch from the cranium all round. There was no meningitis, and the drainage-tubes appeared to be acting well. Mr. Morton commented on the fact that although the drainage of the ventricle had been maintained continuously for two months after the first operation, yet the head had increased in size from excessive fluid pressure.

Dr. JAMES TAYLOR congratulated Dr. Clarke on the successful result in his case. It was not often that one saw a case of recovery from hydrocephalus, even after surgical measures, and for a case to recover after medical measures was rarer still. He had noted in some cases of recovery from hydrocephalus that the child seemed abnormally sharp and above the average in intelligence.

Dr. G. A. SUTHERLAND thought that recovery in cases of congenital hydrocephalus was not so very uncommon, the commonest underlying cause being syphilitic meningitis, and the cure being effected by a prolonged mercurial course. As regards the acquired cases, many of which dated from an attack of non-tuberculous basilar meningitis in infancy, he thought that medical measures were useless, and that the most hopeful line of treatment was by surgical intervention on the lines described by Mr. Morton.

Mr. CLEMENT LUCAS also viewed the condition of hydrocephalus as due to mechanical obstruction, and had made various attempts to remove the ventricular fluid. He had tried to drain the ventricle into the tissues beneath the scalp, but had not found absorption take place in that region. As regards other operative measures, it seemed impossible at present to descend to the base of the brain, but he thought advances would be made in that direction, for it was only necessary to let the fluid communicate sufficiently freely with its proper arachnoid space for the cases to be cured.

Dr. GEORGE CARPENTER agreed that many of these cases were syphilitic in origin, and had seen at least half a dozen of them cured by mercury and chalk.

Mr. J. LACY FIRTH showed a case of "Congenital Dislocation of the Hip," which had been under treatment by the Lorenz method for four months.

Mr. A. H. TUBBY thought that this method would only bring about cures in comparatively slight cases, namely, those in which the head was quite near to the acetabulum, and was of a good shape, and the acetabulum was widely open. The results, so far as they had gone, might be classified under three heads—(1) actual reposition, (2) good or fair results, (3) no result at all. He could not state the actual number of repositions, but it was comparatively small. The results which were good or fair were those in which the posterior displacement had been altered to an anterior displacement, but without complete reposition. Such patients walked better, some shortening disappeared, and they lost the lordosis. If anything like

excessive force was called for he thought that it was the surgeon's duty to desist, as when force was employed it was almost certain to result in a bad dislocation.

Mr. PAUL BUSH showed a child with extroversion of the bladder. A portion of the mucous membrane had "skinned over" under the constant application of a saturated solution of boracic acid. He proposed doing the old operation of turning over an upper central flap, and covering this by sliding two lateral flaps over it.

## British Health Resorts.

### III.—BUDLEIGH SALTERTON.

[BY OUR SPECIAL MEDICAL COMMISSIONER.]

ALONG the semi-circular sweep of the southern seaboard bounded by Portland Bill on the east and Start Point on the west, there are many places of merit as desirable health stations. Among these, Budleigh Salterton deserves mention. It is near to the estuary of the Exe and close to the mouth of the River Otter, and only five miles from popular Exmouth. It is a quiet little town of modern construction, which the extension of the South-Western Railway, opened in 1897, has made conveniently accessible. Well sheltered on the north it is less open to the south and south-east, and presents the usual advantages of a warm southerly seaside resort. The climate is mild and equable. The rainfall is moderate, the mean average of seven years being 26.82 inches. The soil is good and the roads dry speedily. Much sunshine usually prevails. Considerable improvement has been made to meet the needs of the health seeker. There is no pier or ambitious pavilion, but the front is conveniently laid out, and the visitor needing quiet and willing to lead a simple life will find much to attract on its cliff paths and inland wooded lanes. There are good golf links near at hand and the district is rich in drives, and offers many attractive walks. The water supply of the town is good and it is proposed to increase it. The drainage appears to be fairly satisfactory and it is proposed to carry the outfall sewer another 48 feet from the shore. (a)

Budleigh Salterton, with its population of about 2,000, is a desirable holiday resort for the wearied worker or town dweller, and it is very suitable for children. At present it cannot offer any very particular advantages for the luxury-loving invalid, but for the fagged brain and jaded body it can provide rest and means for enjoyable open-air life.

Dr. T. N. Brushfield, in his attractive little guide, claims that Budleigh Salterton is well fitted for the treatment of many cases of pulmonary consumption, the equable temperature and mild winters being particularly suited for the conduct of open-air life, so essential for the patients. "The climate benefits many cases of spasmodic asthma often modifying and lessening the painful attacks, especially in those who come from inland places."

Rheumatism is rare and rheumatic subjects, perhaps owing, at least in part, to the absence of a clay subsoil, do well. Cases convalescing from zymotic diseases should do well here. Delicate and rapidly-growing children will find ample opportunities for health-giving occupation out of doors. Invalids and aged will find the peace and quiet peculiarly attractive. Efforts are being made to develop Budleigh Salterton as a winter resort.

The hotel accommodation is at present somewhat limited, but furnished apartments in good positions can usually be obtained. Budleigh Salterton is easy of access. It is 170 miles from London and is reached by the London and South-Western Railway, *via* Sidmouth Junction and Tipton St. John, or through Exeter and Exmouth. During the summer months a fast train leaves Waterloo at 11.20, reaching Budleigh

Salterton at 3.59. Fortunately for the peace and quiet of this desirable resort there is no Sunday service of trains.

PARIS, July 24th, 1904.

### POISONING BY CAMPHORATED NAPHTHOL.

M. GUINARD sounded a cry of alarm at the meeting of the Société de Chirurgie, *à propos* of injections of camphorated naphthol. A patient, *æt.* 28, of otherwise healthy appearance, entered the hospital for a voluminous cold abscess on the right side of the neck. The purulent collection was tapped with Potain's apparatus, giving issue to a certain quantity of pus, which was immediately replaced by an ounce and a half of camphorated naphthol, introduced by a cannula. Five minutes after, the patient was seized with epilepsy, initial cry, biting of the tongue, sanguineous saliva from the lips, clonic spasms followed by tonic spasms, with general stiffness and threatening asphyxia. After several struggles, the patient succumbed, in spite of every artificial means used in such cases.

After this accident, M. Guinard searched in medical literature for any similar cases, and found eight deaths and fourteen cases of grave poisoning. Now this agent is very frequently employed by practitioners for tuberculous ganglions. Of the eight fatal cases collected by M. Guinard, four were previously published, and in no case was it possible to incriminate the quality of the liquid injected nor the dose employed. In the fatal cases cited the dose was 5 c.c. in two patients, in others 10, 20, or 25 c.c., and in one only  $\frac{1}{2}$  c.c. was used.

The symptoms of poisoning were generally the same, epileptic seizures, convulsions, fainting, face congested, with respiratory trouble, arhythmic pulsation of the heart, death.

These symptoms occurred very rapidly after the injection—from a few minutes to three-quarters of an hour. In five of the above cases they were observed two minutes after the injection. Death followed in ten minutes in one case, and one, two, or three hours in the others.

What is the toxic agent? asks Dr. Guinard. Is it the naphthol, the camphor, or the mixture of both these agents?

Numerous experiments were made on animals to find an answer to this question, and the following conclusions were arrived at:—

1. Camphorated naphthol possesses toxic properties.
2. The camphor alone produced the symptoms of poisoning, as camphorated naphthol represents an intimate molecular combination, and that the camphor was more soluble than naphthol; it is, therefore, rational to attribute to the camphor the symptoms observed.
3. It is demonstrated that camphorated naphthol is more toxic than spirits of camphor, camphorated oil, or naphtholated spirit taken separately.
4. As naphthol alone is toxic to some extent, it may be inferred that when combined with camphor the toxic properties are greatly increased.

In face of such evidence, M. Guinard rejects systematically all preparations of camphor and naphthol, regarding them as highly dangerous and by no means indispensable to the cure of tuberculous ganglions.

### DIAGNOSIS OF ATAXY.

The incipient stage of ataxy, says Dr. Milian, is extremely insidious, or hidden behind some functional symptoms leading the unwary astray. One patient

(a) "Summary of the Reports of Medical Officers of Health for South Devon" (1902). By William Harvey, F.R.C.S. Exeter: Devon County Council Offices, 1903.

will complain of lancinating pains, which he attributes to rheumatism; another of gastric trouble resembling ulcer of the stomach, and so on. Yet it would be of the greatest interest to the patients if the diagnosis of locomotor ataxy were affirmed at the outset, as, if the mercurial treatment has any chance of success, it is at this stage only. To reach this end it is necessary that the syphilitic patient be followed more or less for five, ten, or fifteen years, and that he should pay periodic visits to his physician to have his nervous system examined. It is for the physician to watch for any symptoms of ataxy.

The examination should bear upon the sensitiveness of certain regions, the reflexes and the condition of the muscles.

Sensation to pain is the most important symptom to study, and a simple pin is sufficient for the purpose. The regions more or less insensible to pain are the little finger, the soles of the feet, and the breast, both in man and woman. There is generally also delay in the perception of the sensations, especially observed in the points furthest from the centres.

The muscular sensation is also affected at the incipient period of the disease; the patient loses the notion of the position of his limbs. In placing one leg over the other in the bed, the patient is unable to tell, eyes closed, their respective positions. In the upright position, the loss of muscular sensation is revealed by the impossibility of maintaining the equilibrium with closed eyes. This sign, known as that of Romberg, can present every degree, from simple oscillation to falling. This sign affects, but to a lesser extent, the muscles of the trunk and the arms. If the patient lies on his back, the legs and thighs drawn up and embraced by the two arms, he will roll to the right or left in his bed as soon as he shuts his eyes.

These different troubles of the cutaneous and muscular sensitiveness should be sought for with care as they are very important in the diagnosis of ataxy.

As regards reflex action, that of the skin is of but indifferent importance, but it is quite otherwise with the tendons, for its abolition is one of the cardinal signs of the malady.

It was for a long time believed that the abolition of the patellar reflex (Westphal's sign) was the first symptom of ataxy, and to a certain extent the idea was correct, but Babinski has shown that the abolition of the reflex of the tendon of Achilles was still more important. It consists as follows: The patient kneeling on a chair, the Achilles tendon is smartly struck above its insertion. The gastrocnemius muscle contracts, producing extension of the foot. One should not be contented consequently, as often happens, to strike the knees of a patient, and because the patellar reflex is present conclude that the patient is not ataxic. An individual can be affected with the disease with the patellar reflex intact, if that of the tendon of Achilles be abolished.

The examination of the patient terminates with the search for the sign of Argyll-Robertson, which consists in the disappearance of the contraction of the pupils in the light; this sign is of great value. Dufour performed an autopsy on a man who had presented the sign of Argyll-Robertson as the only clinical symptom of locomotor ataxy, and he found the anatomical lesions of the malady of Duchenne, that is to say, sclerosis of the posterior roots.

With this systematic exploration of the patellar and Achillian reflex, luminous reflex, sensitiveness of the sole of the foot, the mammary region and the little finger the malady can be recognised at its outset.

## Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, July 24th, 1904.

At the Surgical Congress Hr. Beck, Carlsruhe, spoke on

### CHRONIC COLITIS AND ITS TREATMENT BASED ON SURGICAL EXPERIENCE.

He said that in chronic colitis the accompanying nervousness was not its cause, but a secondary symptom. The patient could not maintain the diet recommended. He had seen and treated for months and years 500 cases (170 men and 330 women). The most important thing was the recognition of the etiological factor, and the treatment must correspond to this. The causes were (1) Diseases of the appendix, the gall-bladder, the other abdominal contents, the uro-genital organs. He had seen 149 such cases. (2) Circumscribed diseases in the colon, such as carcinoma (31 times), tuberculosis (7 times), actinomycosis (twice). (3) Acute gastritis, alcoholism, nicotinism and other harmful effects on the stomach, such as gastroptosis. The majority of cases were those of women suffering from uro-genital affections and changes in the abdominal interior from pregnancies; 257 cases were treated successfully by operation. Of the 243 cases not operated on operation was recommended but declined in 120. No improvement had taken place in these cases. Cases caused by abuse of alcohol and tobacco, cirrhosis of the liver and chronic nephritis were not cured. In six cases the whole of the colon was put out of action by ileo-sigmoidostomy. Five of these cases were cured; one in which Murphy's button was employed died.

At the Society f. innere Medizin, Hr. A. Plehn reported

### TWO CASES OF TUMOUR OF THE CENTRAL NERVOUS SYSTEM.

The first was that of a young woman, æt. 23, who had passed through the usual illnesses, had suffered from visual disturbances for a long time after diphtheria, but had finally lost them. From her childhood her voice had been nasal, hearing on the left side was bad, and she had been anæmic for a long period. In January, 1903, she had a child which was healthy but had snuffles. There were no symptoms of syphilis. Since March, 1903, she had complained of headache, which extended from the forehead to the occiput, and was accompanied by vomiting. There were loss of appetite, wasting and weakness of sight. She was admitted into hospital in September last. Examination showed swelling of the inguinal glands and those of the neck, slight difference in the pupillary reaction and broad nodules in the skin of the abdominal wall and over the scapula, which were believed to be fibromata. The nervous system was otherwise sound. An ophthalmological examination showed changes in the fundus oculi, the papillæ were only recognisable by the course of the vessels, slight clouding. As these symptoms roused a suspicion of syphilis, pot. sod. was given, and as some improvement appeared to follow it, the dose was raised to 7 grms. pro die and inunction was begun. After this the general symptoms improved very much, and particularly those in the fundus oculi. Syphilis was now thought certain. The patient was discharged from hospital, but reappeared two months later with the condition very much worse. She complained of violent headache, especially in the neck, and of great disturbance in hearing and seeing. Examination showed the same condition as before, but with perforation of the left tympanum; there was also purulent

catarrh of the middle ear, although there was none when she was in hospital before. The former diagnosis of syphilis could not therefore now be maintained, the symptoms pointed rather to tumour in the brain and probably in the posterior fossa. Potassium iodide was again given as it was also useful in tumours that were not specific, with improvement in the symptoms. Lumbar puncture showed an intraspinal pressure of 400 mm. of mercury, which sank to 270 when 8 ccm. of cerebro-spinal fluid had been drawn off. Still violent headaches and vomiting came on. On puncture a few days later the pressure was reduced from 270 mm. to 110, when serious trouble arose. In one night following there was extreme collapse. Two days later there was sudden extreme difficulty of swallowing and bulging forward of the right velum palati and the right part of the wall of the pharynx. These symptoms gave rise to a suspicion of pus; they subsided to some extent, however, later and remained stationary from February to June 22nd last, when the patient died from collapse. During the whole course of the disease there were no disturbances of the nervous system, except towards the last slight facial paralysis.

The second case was that of a man who was admitted into hospital on June 3rd in a state of stupor. So far as could be got out of him he had had a stroke about three weeks before. There was slight left-sided paresis, circumscribed œdema of the face, nose, forehead, and both eyelids, the veins of the skin in the parts dilated and tortuous. Later on there was blocking of the ophthalmic vein at the base of the orbit, and it was assumed that the compression was caused by a neoplasm. Lumbar puncture was performed, but scarcely any fluid escaped, possibly in consequence of obliteration of communication from the brain to the cervical canal by a tumour. The urine was normal. Eventually the man died.

Hr. Bender observed that the chief interest of the cases rested on the slight correspondence between the clinical symptoms and the anatomical condition. In the first cases there were widespread tumours in the peripheral and central nervous system, and in the second carcinose necrosis of the skull, but no tumour in the brain itself. The tumours in the first case were fibro-neuromata, the chief tumour being in the meninges of the cerebellum.

## Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, July 24th, 1904.

### THEORY OF THE STREPTOCOCCUS SERUM.

At the Congress for innere Medizin, Menzer drew attention to his sera of streptococci, which he had not transmitted through animals before applying them to acute rheumatism with excellent results. They are especially useful in that form of transmissible rheumatism. He has recently applied some of this serum in mixed tuberculous cases with equally good results, but he would like to have more experience in the latter before dogmatizing on the subject.

Aronson thought that the febrile reaction obtained by Menzer was due to the transmission of a toxin into the system. The serum used by himself caused no fever.

Wolf was of opinion that the fever might be the result of an endotoxin.

Michaelis asked Menzer if he used the same serum for articular rheumatism as he did for the tuberculous cases. If this were so there must be a great difference

in the streptococci, as the purulent result of tubercle is very different from articular rheumatism, where no pus ever occurs.

Menzer said the serum from the same animal contained different streptococci. If Aronson got no reaction or fever with his serum the probability is that it was below the necessary strength!

### CROUPOUS PNEUMONIA.

Stuertz gave a history of his experiments with the sputa of croupous pneumonia on white mice, which died in the same manner. The virulence and clinical symptoms were the same in both mice and men, which led him to believe that this test might be of prognostic value in forecasting the result of a case when the attendant is placed in the difficult and doubtful position of depending on the varying symptoms that are usually manifested in these doubtful cases, where one exacerbation after another points to intervals of morbid progress and ultimate exhaustion.

### HEPATIC LEVULOSE UREA.

Strauss said that he had examined upwards of a hundred cases with levulose in the urine, and found that 80 per cent. of these cases suffered from hepatic disease, which left 20 per cent. for genuine alimentary levulose. Sachs, under his own guidance, had demonstrated that with levulose in the muscles no distinction could be discovered between glycogen and dextrose. Again, Schrot was unable to isolate levulose from a mixture of pancreas and muscle, while dextrose was easily distinguished. He concluded from these results that the synergia of muscular movement had no part in the production of levulose. This was diametrically opposed to Schlesinger's experiments on dogs. He found that it was easier to obtain the levulose product than dextrose. Whatever the cause may be in dogs, the hypothesis is negatived in man.

### OCULAR SYMPTOM IN DIABETES.

Krause drew attention to hypotonia, or peculiar ocular symptoms in diabetic coma that are never generally acknowledged, which appears about fifteen or thirty-two hours before death. This symptom does not appear in morbus Basedowii, Addisonii, uræmia or other febrile attacks of an obscure nature, where sudden comatose conditions often arise and may require to be differentiated. It presents itself in both bulbi, but how to explain it Krause would not presume to hazard an opinion. He had to admit exceptions, as in eighty diabetic cases of coma that ended fatally eighteen had no hypotonia during life. He suggested that the symptom might be caused by low pressure in the blood-vessels produced by hydration or hæmatic dyscrasia. This hypothesis could not be borne out by experiments on animals, as dogs treated with acetone, acetic-acetone-ester,  $\beta$ -oxybutyric salts, and phlorodizin never had the symptom during life, although the drugs administered had been used differently, sometimes by the mouth, at other times subcutaneously. Other dogs had the pancreas removed, the animals dying of diabetes; but no hypotonia was present at any time. The anatomical examinations of the bulbi revealed no morbid condition in the eye itself.

### MOTOR FUNCTIONS OF THE VAGUS.

Starck gave the results of his research on the motor function of the vagus. The elements in this phenomenon were cardio-spasm, paralysis of the œsophageal muscles, and atrophy of the vagus. He divided his experiments into two positions, *viz.*, resection of the nerve above the hilus, or division of nerve into the lung, and that below the hilus. Section of the nerve always removes the inhibitory action on the cardia, but this is not of long duration, and must be considered temporary.

Resection of the nerve below the hilus of the lung produced no dilatation of the œsophagus; neither did it cause any weakening of the heart. When the section was made above the hilus, on the contrary, dilatation and tachycardia resulted. Vagus atrophy may therefore be charged with producing dilatation of the œsophagus when no hypertrophy of the muscle is found, as a paralysed muscle is not likely to become so. He concludes with the assertion that when we meet with hypertrophy and dilatation in the œsophagus we may affirm that the cause is not degeneration of the vagus.

### The Operating Theatres.

#### CHELSEA HOSPITAL FOR WOMEN.

**ABDOMINAL PANHYSTERECTOMY FOR CARCINOMA OF THE BODY OF THE UTERUS.**—Dr. A. GILES operated on a woman, æt. 53, with the following history: Six weeks before admission she had been under the care of Dr. Townsend Barker, complaining of hæmorrhage, for which he asked Dr. Giles to see her. The uterus was found at that time only slightly enlarged, and it was decided to dilate the cervical canal and explore the uterine cavity, as there seemed to be a probability of carcinoma of the body of the uterus. This was done, and some rather soft fragments were removed by the curette; they were sent for microscopical examination and report to the West End Pathological Laboratory, and Mr. Eastes reported that the growth was carcinoma. It was then decided that she should go into hospital for hysterectomy. The patient, though married, had had no children, and the vagina was rather narrow. In view of this fact and of the situation of the growth in the body of the uterus, the abdominal route was decided upon. The operation performed was panhysterectomy by Mr. Bland-Sutton's method, and both appendages were removed in one piece with the uterus. The method referred to is as follows: The broad ligaments are clamped off with forceps in the usual way and divided up to the side of the uterus, the uterine arteries are seized with forceps, the bladder reflection is turned down in front, and a small peritoneal flap is fashioned behind. The uterus is divided just above the point where the uterine arteries are seized, but the line of division, instead of being carried straight across the uterus as in the ordinary supra-vaginal amputation, is made to pass downwards and inwards on all sides, so that eventually the vagina is opened and all that is left behind of the cervix is a thin outer shell, and the portion removed shows a tapering lower extremity tipped by the os externum and a small portion of the vaginal mucosa surrounding it. The arteries are then tied off, and the peritoneal flaps brought together by a continuous suture of fine silk. The abdomen is closed by the usual triple layer method. Dr. Giles said that this case was a very suitable one for the method employed, because this allowed for the complete removal of the uterus and appendages in one piece, and much more satisfactorily than could be done by vaginal hysterectomy. When carcinoma affected the cervix it was of course necessary to remove the whole of the vaginal covering of the cervix, and this could be done properly from the vagina, but in a case where the growth affected the body of the uterus the removal of the vaginal covering was less important than free removal of the broad ligaments. The advantage which Mr. Bland-Sutton's method of panhysterectomy presented over other methods was that as the dissection was carried out within the outer capsule of the cervix, there was no possibility of injuring the ureters or the bladder. The method was devised for dealing with uterine fibroids, but was useful also

for cases of carcinoma of the body of the uterus. The whole organ in this case was small, affording an example of that interesting class of case in which carcinoma develops in an atrophic uterus after the menopause.

The patient made an uninterrupted recovery, and left hospital on the seventeenth day after operation.

#### ST. GEORGE'S HOSPITAL.

**OPTICAL IRIDECTOMY.**—Mr. H. B. GRIMSDALE operated on a girl, æt. 25, who had been suffering from severe recurrent iritis, as a result of which the iris became totally adherent to the lens and the pupil blocked with lymph. Mr. Grimsdale pointed out that an operation was necessary for two reasons: in the first place, to re-establish communication between the posterior and anterior chambers and thus to prevent the onset of secondary glaucoma, and, in the second place, to form a new pupil, since the natural one was useless for visual purposes owing to the lymph on the lens capsule; vision had been reduced in each eye to recognition of the movements of the hand at two feet distance. He also said that this necessity governed the choice of operation, as ordinarily to prevent glaucoma the surgeon would make his coloboma in that part of the iris which would be covered by the upper lid; but here it was necessary that the gap in the iris should be exposed. Mr. Grimsdale made an incision with the keratome, having an extent of about eight millimetres in the lower and outer quadrant of the cornea; he then introduced a pair of Dr. Wecker's scissors closed through the wound until the points reached the pupil. Then they were allowed to open slightly, and a small fold of iris sprang up between the blades. On closing the scissors this fold was cut off and withdrawn with them. The same operation was then performed on the other eye. A drop of atropine solution was instilled into each eye, and a pad and bandage applied. Mr. Grimsdale said this was a form of operation devised by Mr. Brudenell Carter, but not very frequently performed. It seemed to him by far the most suitable for such cases as the present. The size of the artificial pupil and its position could be selected, and varied at the surgeon's will. It was most important for good vision that the iridectomy should be small, and he reminded the onlookers that a small iridectomy suffices in secondary glaucoma. If the iris be drawn out of the wound with forceps the fold that is cut off is necessarily larger than the part excised in the method he had employed, and, further, the natural pupil is often partially freed from its attachments to the lens so that two functional pupils remain, giving rise often to diplopia. It had been objected to the method that a wound of the lens capsule, and consequent traumatic cataract, was not unlikely. If the points of the scissors were allowed to enter the pupillary region such an accident might occur, but, if they were kept, as he advised, outside the pupil, it was difficult to see how such a *contretemps* could happen. As to the result of the operation, he referred to a case which had been treated in this way two months previously. The patient, a boy, æt. 12, had a similar defect in his left eye to that of the present patient. His vision was only capable of counting fingers at two feet distance. A fortnight after the operation it had risen to  $\frac{5}{6}$ .

#### Exposing a Scarlet Fever Patient.

At Malvern, Frank Ganderton, of independent means, residing at Malvern Link, was summoned at the instance of the District Council for failing to notify that his son, aged five years, was suffering from scarlet fever, and also for exposing the child to the danger of the public health. The evidence showed that the child was in bed for a week, was sick, had sore throat, swollen glands, and rash. Whilst in the desquamating stage the child was sent to school. The parents swore that they had no suspicion of scarlet fever. The Bench inflicted a fine of £2 and costs.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, JULY 27, 1904.

**THE DIMINISHING BIRTH-RATE.**

THE birth-rate of any given community clearly affords data of great value as regards the moral and materia' welfare of its citizens. It does not follow, however, that the significance of variations in the birth-rate is always rightly interpreted. So far as that goes, indeed, the whole matter appears to be on the borderland where laws are beginning to loom from the dense mists of half knowledge and speculation. Hence it is in the highest degree desirable that the laws which govern the birth-rate should be freely and adequately discussed by competent observers. Unfortunately, the subject has been generally tabooed because of its close relationship with the prevention of conception among married folk. If that be a great social evil, as many moralists would have us believe, it is surely a mistaken policy to ignore its existence. The sounder attitude of our moral teachers would be to gauge as far as may be the true inwardness and the full relations of that particular practice before arriving at a working decision. The Church has ignored prostitution, but that vice stalks rampant through our streets, and exacts a terrible toll of misery and destruction from the innocent as well as from the guilty. But signs are not wanting that the clergy of the United Kingdom are ready to speak out upon the birth-rate question. The Bishop of Ripon and other distinguished churchmen have spoken publicly upon the decline of the birth-rate, as brought forward by Dr. Taylor, of Birmingham, in an address published in our own columns in March of the present year. The publication of that article has given rise to universal interest and discussion in all classes of society. The main conclusion was that the decline of the national birth-rate was due to practices of prevention among married persons, and that the unfortunate practice in question was attended by

evil results both physical and moral. Great credit is due to Dr. Taylor for his courage in bringing forward a difficult subject in so clear and delicate a way. His article raised momentous issues, and was clearly inspired by a strong personal sense of social and moral obligation. His audience was primarily medical, and his communication published in a medical journal. His views, however, have not been allowed to pass unchallenged by his own profession. His contentions are analysed critically and discussed in two articles by Dr. David Walsh, published in the issues of THE MEDICAL PRESS AND CIRCULAR for July 13th and 20th. It is impossible to enter at length into the various points raised in the second paper. Briefly, Dr. Walsh admits that there has been a fall of 5·2 per 1,000 persons living during the past half century. At the same time he says there is no evidence to show that the fall is due to a condition exclusively affecting married life. A similar decrease of births has affected illegitimacy, a fact not considered by Dr. Taylor; yet that, taken with the ever-increasing later period of the marriage age, would together account for a great deal of the fall. The birth-rate of 1900, again, is practically the same as that of 1840. Thirty years of rapid increase were followed by thirty years of fall. Is it possible that the United Kingdom is nearing its limit of supportable population, and that the falling birth-rate is a delicate index of waning prosperity? There is little doubt that preventive methods prevail in the higher ranks of society. Probably it is only a question of time for similar practices to permeate to the poorer classes. A crucial question is how far this kind of "intellectual limitation" of families overlaps the moral obligations of the citizen. The subject is one of the most complex, and at the same time most important, that could engage the attention of the social, the scientific, and the moral reformer. In our opinion, Dr. Walsh deserves careful attention when he suggests that the soundest remedy for a waning birth-rate may possibly or probably be found in laws that lead to greater equality in the distribution of wealth, and of opportunity to the individual citizen.

**IS A HOMŒOPATH A QUACK?**

AN interesting libel action was lately tried in Germany, the plaintiff being Dr. Mende-Ernst, a homœopathic practitioner of Zürich, and the defendant Dr. Spartz, the editor of the *Muenchener medizinische Wochenschrift*. Dr. Spartz's journal had published an article in which Dr. Mende-Ernst was referred to as "the well-known charlatan and homœopath," a conjunction of designations to which the latter look strong exception, so much so that even after Dr. Spartz had published an announcement that Dr. Mende-Ernst was a duly qualified medical graduate of Zürich he found himself sued for libel by the indignant homœopath. A number of witnesses, including von Winkel, the great authority on forensic medicine, were called by the defence to show that,

however well a man might be qualified in the view of the law, from the point of view of scientific medicine he deliberately placed himself on a level with charlatans when he embraced and practised the exploded system of Hahnemann. von Winckel quoted the amusing dictum of Müller that the principles of homœopathy seemed to him to be about the same as if after a man had been run over by a wagon he should be treated by having a toy-cart run backwards and forwards over him three times; and he showed, moreover, how homœopathy is used to hoodwink and deceive the public, just as much as frank charlatanism is. Spartz, in his evidence, dwelt on the fact that homœopaths were in reality worse than quacks, in that they had been instructed in the scientific basis of medicine and had eschewed it in favour of ridiculous doctrines, such as that the "intellectual vital force was dynamically out of time," and that it was inconceivable that any man who had been taught pathology could act so from conviction. The other scientific witnesses spoke to the same effect, saying that from the point of the profession homœopaths rank as quacks. As it happens, however, the Bavarian law recognises homœopaths, and in the end the editor had to pay a nominal fine and costs, although it was clearly established that there was no question of personal malice. For a long time past the homœopaths, in this country at least, have been holding out the olive branch to those whom they are pleased to call "allopaths," or "antipaths," for they are tired of being cold-shouldered by the self-respecting members of the profession, and they are willing, as expressed by the mouths of some of their leading spokesmen, to give up their sectarian character. No doubt it would suit them well to be able to meet scientific physicians in consultation in dangerous cases, and to have eminent surgeons to operate on their patients when they are in difficulties, so long, that is, as they can retain the hold that they have on the section of the public who see magic in the blessed word "homœopath." But the homœopathic practitioner cannot have it both ways, and while he professes to practise a hole-in-the-corner system he cannot expect scientific men to meet him and recognise him as one of themselves. In this country, as in Germany, it may not be legal, or even scientific, to call a homœopath a "quack," if a quack is taken to be "a boastful pretender to medical skill that he does not possess," but the gulf that separates the man who holds the pathology of disease to be the basis of rational treatment from one who holds that pathology is irrelevant to treatment, and that the "vitality of symptoms" is the true guide to the prescription, is one that cannot be bridged. The homœopath of to-day is certainly very far removed from the enthusiast who held that the "itch was the cause of seven-eighths of all chronic diseases" and that "by the trituration and succussion of drugs there is an actual exaltation of medicinal power, a real spiritualisation of the dynamic property, a true, astonishing unveiling and

vivifying of the medicinal spirit." They have indeed given their master the go-by in almost everything; they do not scruple to use remedies that confessedly act on allopathic principles, and they admit the virtues of such a radical antipathic ally as surgery. In fact the homœopath now is very much of an eclectic, and when he hears a method of treatment is doing good he does not wait to see if its acts on the "similia similibus" or the "contraria contrariis" principle before adopting it in his practice. He reserves his globules of bryonia and his pilules of pulsatilla for old ladies who have not much wrong with them, and for children who will get well if not treated much with anything, and if taxed with inconsistency, he will exercise a deal of casuistry to show that a potent treatment, such as antitoxin in diphtheria, is quite admissible under homœopathic rules. Indeed, the most wonderful thing about the modern homœopath is his aptitude for sophistries, and the amount of ingenuity he can expend on showing that in spite of all appearances he remains a homœopath is worthy of a better cause. But in so far as the homœopath is removed from a quack and approaches to "allopathic" standards, it is difficult for the unsophisticated to believe in his disinterestedness, and, quack or no quack, it behoves the medical profession to give him a wide berth while he continues to obtain practice on the pretence of having some esoteric principle up his sleeve. When he confesses that he is prepared to drop his sectarian title and to do what is best for his patient, irrespective of system or creed, it may be feasible to absorb him into the general rank of the profession. But that day is not likely to come in this generation.

### Notes on Current Topics.

#### Hypnotism in the East.

THERE is no doubt that Oriental medicine has not received all the attention it deserves from Western inquirers. Eastern civilisation has been for so many centuries stationary that all old beliefs, being freed from that healthy spirit of scepticism which is necessary for the preservation of truth in its purity, have naturally become crusted over to such an extent as to render their meaning obscure and their value indeterminate. To multiply metaphors, as Sancho Panza does proverbs, there is but a halfpenny-worth of bread to an intolerable deal of sack, or, in plainer language, a grain of corn to a bushel of chaff. Still, to the curious there is often much interest in turning over the chaff to find the grain, which may be, moreover, a good sound one when discovered. Several of what in these countries and in our new civilisation we are accustomed to consider most modern methods of treatment have, in fact, been known in the East for ages. Readers of "Kim" will remember Mr. Kipling's description of massage as practised in India, and as it was practised there centuries before its introduction into Western therapeutics. Indeed, we cannot but notice the

similarity between the treatment undergone by Kim after his exhausting journey and the method of treatment associated with the name of Dr. Weir Mitchell. Similarly, the induction of anæsthesia for surgical purposes is part of the old knowledge of further India, while many of the phenomena of hypnotism, known to us here only in this generation, have been made use of for all sorts of purposes "east of Suez" as far back as history goes. In the Malay Peninsula the hypnotic state is known under the name of *latah*, and is clearly recognised by the natives. Dr. Percy Gerrard has recently reported (a) an interesting case which came under his own observation, in which the hypnotic state could be easily induced by giving the patient a sudden shock of any kind. An unexpected clapping of the hands, a shout, or a poke in the ribs was sufficient to reduce the patient, a young and intelligent Javanese woman, to the condition. The duration of her paroxysm was in direct proportion to the period of continuance of the excitement, but usually, when left alone, she quite recovered herself in about half an hour. While in the condition of *latah* she scolded and jabbered in violent and meaningless language, but was entirely amenable to commands given her by bystanders. We hope Dr. Gerrard will be able, as he promises, to pursue his researches further into this interesting condition, and its occurrence in the Malay.

#### "Single Cases" of Lunacy.

THE report of an inquest at Battersea last week shows, if demonstration be needed at all, the necessity for some such measure as that which the Attorney-General is trying to pass into law this Session. This Bill, which has already been commended in our columns, seeks to give power, on single medical notification, for a patient who shows signs of mental aberration to be placed for a period not exceeding six months in the private house of a medical man for observation and treatment. Such a measure meets those cases of slight mental disease which need care and supervision, and which a medical man hesitates to certify as insane and send to an asylum. In the instance under notice, a Miss Ellen White first developed some delusions on May 16th, and Dr. Needham, of Clapham Park, was consulted. He advised her sister that she was insane and should be removed to the infirmary, but the sister was shocked at the idea, as relatives always are, and it was arranged that Dr. Needham should try to get her into a licensed house. This, however, could not be managed, and eventually she was taken into a private nursing home at two guineas a week. Under a course of bromide she became rational in the course of a fortnight, but great weakness set in, and she was eventually removed to the infirmary, where she died. The Coroner closely examined Dr. Needham as to the insanity, and he stated, in reply to the questions, that he was not certain that she was a lunatic, and that he did not care to fill up a certificate

on the evidence he found; moreover, that it was a common custom to keep patients in a home prior to certifying them. After hearing the witnesses, Mr. Troutbeck proceeded to make some strong remarks as to the propriety and legality of keeping a lunatic in an unlicensed house, and the jury, in finding that the death was from natural causes, expressed the opinion that a further inquiry should take place. No better example of the difficult and delicate situation in which medical men so frequently find themselves placed could be given than this; nothing shows more plainly the urgency for legalising the practice of providing a half-way house for slight and incipient cases of insanity. The fact that in this particular instance some doubt is thrown on the skilled nature of the nursing does not invalidate the general proposition.

#### A Historic Drug House.

THE announcement that Messrs. Francis Newbery and Sons, of Charterhouse Square, have converted their business into a limited liability company recalls some interesting particulars with regard to the history of a mercantile concern which, by reason of its antiquity, is, we think, unique in the drug trade. It is almost one hundred and sixty years since John Newbery, a seller of drugs at Reading, came to London and started business in St. Paul's Churchyard. In the same year we find him entering into a contract with Dr. James for the sale of his famous powder. He and his son Francis seem to have early acquired a reputable name among the citizens of London, and we find them on terms of intimacy with Dr. Samuel Johnson, for the great lexicographer is noted as being present at a house-warming given in 1779 by Francis Newbery on his removing into another house in St. Paul's Churchyard. This was the second move made by Newbery's business, without leaving the Churchyard, but it now remained in the same house for exactly ninety years. Between 1869 and the present, however, no less than three changes have been made before reaching its present quarters. The directors of the new company are the great-grandsons of the original John Newbery, and the concern has descended regularly from father to son through its whole history.

#### Magnetic Opium.

THE subject of hypnotism and its allies has always been one in which our French *confrères* have taken the keenest interest, and marvellous indeed were the tales—they have not been so common of late—that used to emanate from the cliniques of their neurologists. Since Mr. Ernest Hart went over to investigate some of the phenomena that were reported, and returned home with a somewhat modified opinion of the perceptive acuity of their authors, things have been quieter. But now and again astonishing stories still appear, and they certainly make interesting reading, if nothing else. In the *Revue de l'Hypnotisme* a tale is told of a young woman

(a) *Dub. Journ. Med. Sci.*, July, 1904.

—most of the subjects are young women—of a restless, impulsive, jealous disposition, who had taken to the opium habit. Far from aggravating her awkward traits of character, and leading her to moral ruin, the opium seemed to act like a charm; she became quiet and demure, careful and economical; in short, a pattern of all the virtues. Instead of being thankful for the change, she was so ungrateful as to give up the drug, and, hey presto! back came the jealousy, the restlessness, the extravagance. Obviously this was a disadvantage, and this erratic young woman determined to subdue her evil tendencies by resorting to opium once more. Welcome success attended her. She became shrewd and cautious, quiet and sedate, reason and reflection yet again characterised her dealings with her fellow-creatures. The *Revue* ingeniously points out that the question would arise in the psychologist's mind whether her morphine personality was not superior to her natural self. But why to the psychologist's only? Would it not be patent to every man with a brain in his head that this elegant young lady's salvation lay in her becoming a confirmed morphinomaniac? We fear if it is revealed to the world that opium has this Dr.-Jekyll-and-Mr.-Hyde effect, a good many people will take to putting laudanum in the drinks of their objectionable relatives to see if they could not be transformed into amiable and lovable creatures, just as anti-dipsomaniac cures are recommended to be slipped into the inebriate's glass when he is not looking.

#### Jaundice and the Widal Reaction.

EVER since the agglutination test, incorrectly ascribed to M. Widal, has come to be relied on in the diagnosis of typhoid fever, exceptions to its application have been noted. On the one hand, certain cases clinically indistinguishable from typhoid fever, but failing to respond to the agglutination test, have occurred. These have now been recognised as forming a distinct entity, not only due to a different organism, but with definite pathological differences, and have been grouped under the common term "paratyphoid fever." On the other hand, a clumping reaction sometimes occurred with blood which came from patients to all appearance free from typhoid fever. In some cases this has been explained by the fact that the patients had in time past suffered from the disease, and the blood had retained its agglutinating power. In others it would seem that the blood has congenitally an agglutinating action towards the typhoid bacillus. On many occasions, however, the positive action has been noted where the only clinical condition calling for attention was the presence of an attack of acute jaundice. So often does this occur that it has even been maintained that the Widal reaction is present as a rule in jaundice. This is not so, however, for many cases of jaundice occur without the reaction being present, and when jaundice is experimentally induced in animals, the reaction is always absent. Several cases of jaundice with

positive reaction have been investigated by Steinberg, in Germany, and by Libman, in America, and both come to the same conclusion that where this condition occurs, it is merely an atypical typhoid infection. It is held that the jaundice in such cases is of infectious origin, the organism being either the typhoid bacillus or some very closely allied organism. In several of Libman's cases, indeed, he was able to isolate the typhoid bacillus. If their view be correct, we are to look on what has been regarded as an exception to the principle of specificity of agglutinating reactions rather as an additional fact in its favour.

#### Noise and Sickness.

To sensitive natures there are few things harder to bear than a succession of unpleasant auditory stimuli. Under certain circumstances the healthy listener can hardly tolerate even harmonious sounds, much less discords against which his whole soul rebels. Men of less sensitive nerve centres cannot understand or appreciate the effects produced by noise of all kinds upon their more impressionable brethren whom they, therefore, consider fussy and irritable. It cannot be denied that there is a good deal of unnecessary noise heard in the streets and other public places of large cities. The shouts of newsvendors, the shrieking of locomotive-engines, the clanging of church bells, and the grinding of street organs are only a few of the unmelodious sounds that might be more or less considerably lessened. That modern disease of the nervous system, neurasthenia, owes no small part of its origin to the effects produced by noise upon the receptive organs and the higher nerve centres. The very existence of a society for the suppression or abolition of street noises is an indication that civilised humanity is beginning to cry out against some of the paralysing influences of modern life, so far as one of the special senses is concerned. Many acute diseases, especially those of the brain, are injuriously affected by noise, and patients are far more likely to do well if nursed by those who are gentle and quiet in their ways than by attendants of loud voice and blustering habits. Dr. J. A. Guthrie, of the United States Navy, has recently commented upon the great value of the "silent signal" in naval manoeuvres, the orders being obeyed with alacrity and without confusion. It is suggested that electrical methods might often be employed as a means of diminishing unnecessary noise.

#### Registration of Nurses

It is a curious fact that a nation like our own, which depends in a greater degree than any other on the product of its brains, should take so little interest in educational questions, and that the interest taken is mostly by way of hindering rather than of advancing the educational cause. This, too, when the other progressive nations of the world are spending more money on education every year. A striking commentary on this state of things is the attitude that most of the members

of the medical profession have taken up in their evidence before the Select Committee of the House of Commons, now sitting to inquire into the subject of the State Registration of Nurses. Dr. Norman Moore, of St. Bartholomew's Hospital, who has had fifteen years' experience of teaching and examining nurses, is of opinion that the qualities that make a good nurse are widely distributed among all classes of the community, and therefore that any steps which tend to raise the standard of preliminary education of nurses would be a mistake, as it would cut out a number who were otherwise fitted for the work. Compare this with what is taking place in America. In the Children's Hospital at Boston arrangements are being made with Simmons' College, a neighbouring women's technical school, by which all would-be probationers, before joining the hospital, are to pass through special courses in anatomy, physiology, chemistry, bacteriology, and sanitation for four months, so that the studies in these subjects may not be interfered with by ward work. After the four months have elapsed the candidates are to go into the Nursing Home for two months for instruction in domestic science, cooking, and the essentials of practical work in a hospital. At the end of this time they will be started on their three years' course of ordinary hospital training. With every regard for those qualities that make a nurse acceptable to sick people, it is impossible to overlook the fact that it is becoming more necessary every day for nurses to have an intelligent practical acquaintance with the work of their profession; and with plenty of candidates always coming forward, it ought not to be difficult to select those who are personally suitable. For our own part we are all in favour of raising the standard of their training and education, and of giving them such benefits as result from registration, both for their sake and that of the public.

#### Stagnin.

A NEW drug that will fill an important gap in pharmacology seems likely to be soon within the reach of physicians. This body was discovered accidentally by Landon, who was working on spleen-substance with a view to proving its usefulness in the treatment of anæmia. In the course of his studies he discovered that spleen-substance, or some body it contains, is possessed of great hæmostatic powers, and that, unlike adrenalin, it produces its effect, not by arterial contraction, but by markedly increasing the coagulability of the blood itself. It is now generally recognised that valuable as adrenalin is for external application, its use for internal hæmorrhage is frequently contra-indicated, as, side by side with the diminution of volume of the arterioles it causes increased general blood pressure, which tends to counteract the good done locally. With stagnin, as Landon has named his new product, this is not so, for it has no local effect on the arteries, and in conditions like menorrhagia and hæmoptysis, when the only chance of bringing

about hæmostasis is by acting on the blood itself, it promises to have a wide field of usefulness. Stagnin is prepared from the fresh spleens of horses by mixing the scraped pulp with salt solution and a little chloroform and alkali. After extraction for twenty-four or fifty-eight hours at 37° C., the mixture is filtered; the filtrate is then evaporated and precipitated with alcohol. A dry powder is eventually obtained which dissolves readily in water to form a clear, yellow fluid. Stagnin has been given by the mouth and by hypodermic injection, but its most marked effects have been produced by the latter method. With the range of organo-therapy developing as it is, we seem likely to be soon in possession of a number of most valuable additions to our armamentarium.

#### The Dustman, Old and New.

IN spite of the excellent way in which, on the whole, the Public Health Acts are administered, there are many weak places which are sufficiently obvious even to the man in the street. The methods adopted for the collection and removal of house refuse, for instance, are often primitive as those of the Far East. In a certain set of lantern slides which are, we believe, still exhibited sometimes by health lecturers, there is an amusing picture of a public official who, in strange garb and bearing a disreputable-looking basket, is dignified by the name of "A London Dustman." Such a spectacle is surely a relic of past times, when sanitation was in its infancy, and it is to be hoped that official has changed greatly since this particular slide was prepared. Nevertheless, there is still much to be desired in the manner in which dust and other refuse is collected. The days of the old brick dust-bins are, happily, ended, at least so far as the metropolis is concerned, and neater and more compact galvanised iron receptacles provided with tightly-fitting lids have supplanted them almost entirely. The householder's premises are now no longer soiled by droppings of ashes or vegetable *débris* from the dustman's basket during his weekly or bi-weekly visits, as was formerly the case, but, on the other hand, we still note the nuisance of spilt dust when bins are emptied in the dust-cart. The latter is frequently a source of much annoyance, especially in windy weather. The better collection of dust was the subject of much discussion at the recent Conference of the London Sanitary Authorities, held at the County Hall, Spring Gardens. One of the best ways of removal of house refuse would be for the full bin to be taken away entirely unopened, and a clean empty one left in its place. The cart bearing the full bins could then proceed directly to a central station, where their contents could be appropriately dealt with.

#### Athletics and Health.

ONE of the commonest comments made by the public in reference to the domination of athletics over the youth of these countries and of America, is that a devotion to athletics is, as a rule, detri-

mental to longevity. The great physical strain undergone, say, in a boat-race or a hard-fought sprint, is said to conduce to heart disease or heart weakness, and wiseacres are always ready to back up their opinion by a reference to "poor So-and-So," who, though the best oar of his time, died before thirty. Those, however, who have taken the trouble to investigate for themselves the after-history of athletes of note have usually come to a contrary opinion. In England an exhaustive inquiry into the health of past members of the 'Varsity crews has shown that their lives are, in an insurance sense, "good" much beyond the average. In the United States more recently Dr. Meylan, of the Columbia Gymnasium, has examined the lives of one hundred and fifty-two oarsmen who had rowed for Harvard in the forty years 1852-1892. He was led to the task by the statement of an old rower that all the other men who had pulled in his boat had died young—a statement proved, on careful inquiry, to be entirely fanciful. Of the 152 oarsmen, 123 are still living, and have most of them been interviewed by Dr. Meylan. Of those who died, six were killed in the Civil War, one in a railway accident, and one in a carriage accident—causes hardly to be traced to the ill effects of athleticism. Of those who died of disease, heart disease accounted for two, pneumonia for three, apoplexy for two, paresis (?) for two, cancer for one, phthisis for one, Bright's disease for two, alcoholism for one, while the causes in the other cases were not to be ascertained. Certainly from such a list it would be hard to trace any direct relation to athletics. An interesting point incidentally discovered by Dr. Meylan is that of the survivors not one has made a failure in life, and most of them have reached the class that was so frequently demonstrated to Martin Chuzzlewit, "the most remarkable men in the country."

#### Heart Massage.

THERE are few things in modern surgery which appeal more to the lay mind, which delights in sensations, than the comparative fearlessness which now marks our attitude toward the heart. Time was, not so many years ago, when any wound of the heart was regarded as necessarily fatal, and when surgical manipulation of that organ would have been regarded as an act of bravado beyond the range of the most ambitious operator. At present, however, suture of the heart has been practised successfully so many times that it is regarded as the direct duty of the surgeon in cases of heart-wound. Manipulation of the heart in another condition has recently presented itself as a legitimate procedure, and calls for general attention. It has been found that in cases of heart failure through collapse, and consequent apparent death, the heart may again be excited to contract by grasping it in the hand and performing rhythmic contractions. This has been performed successfully in some cases, and, as the patient was all but dead at the moment it was undertaken, no question of added risk in opening

the thorax need arise. Particularly when collapse occurs during the course of a severe abdominal operation, if other measures for restoring cardiac activity fail, and if the heart cannot be grasped through the diaphragm, it would appear to be the duty of the surgeon to incise that membrane, and perform rhythmic contractions of the heart. It is possible, too, that in cases of apparent death from drowning, heart massage may succeed where other measures fail. This is certainly the case with lower animals, as Professor Richet, of Paris, is in the habit of demonstrating in the case of dogs. It is likely, indeed, that the ordinary movements made in performing artificial respiration act, not only on the lungs, but also, by pressure on the heart walls, as a mechanical irritant to the heart itself.

#### A New Disease.

DR. BYROM BRAMWELL recently brought to the notice of the profession a curious case of infantilism, which he believes to be due to the absence or atrophy of the pancreas, or, at any rate, the absence of the pancreatic secretion. When first seen two years ago, the patient, a lad of eighteen, did not appear to be more than eleven years of age. He was well proportioned, bright, and intelligent, but had not grown during the previous seven years. He suffered from chronic diarrhoea for many years; the urine was free from sugar. Several tests were employed which demonstrated that no pancreatic juice reached the intestine. Dr. Bramwell immediately started treatment with pancreatic extract, and the result seems to support his diagnosis. The diarrhoea has ceased, and the bodily development is very marked, the patient having increased five and a half inches in height, and a stone and a half in weight. The sexual organs, which two years ago were infantile, are now developing normally, and the voice has become masculine. Dr. Bramwell thinks that the condition has not hitherto been recognised, and suggests that where it has occurred it has probably been mistaken for sporadic cretinism, though the points of difference are obvious enough.

#### Nurses' Slander Action.

AN action was heard at Londonderry on July 21st, in which eight nurses employed in the Derry Workhouse Hospital sought to recover damages for defamatory words stated to have been used by a female guardian, Mrs. Morris. This person, since her election to the Board a few years ago, appears to have made herself, in the words of her own counsel, "a holy terror" to all connected with the workhouse—guardians, doctors, and nurses. The slander complained of consisted of speaking of the nurses as "brazen-faced strumpets" and "lying tinkers," "a bad lot," and stating that whereas they had formerly "decent nurses" in the hospital, they had none now. Though denying that the words had the defamatory sense attributed to them, the defendant admitted that she had spoken of some of her fellow-guardians as "rotten Catholics." A verdict was brought in for the plaintiffs, with assessment of

damages at one shilling in each case for each plaintiff. It is hard to see what principle guided the jury in fixing the damages at a trivial sum, unless they thought that the words of such a person as Mrs. Morris were not likely to carry sufficient weight to injure the plaintiffs to any substantial degree. At the same time it is unfair that the nurses have to pay heavy costs for the protection of their characters.

#### Intestinal Diverticula.

It is only within the last few years that acquired diverticula of the intestine have come to be regarded as anything more than pathological curiosities. Recent observations, however, show that they are much more common than were formerly supposed, and in the bowels of old people they are probably very common indeed. They occur both in the small and large intestine, most commonly in the latter, and vary considerably in position and size. In the small intestine, the diverticulum usually, but not always, penetrates between the two layers of the mesentery, while in the large, the commonest site is immediately beside one of the longitudinal muscle-bundles. In size, they are rarely larger than a walnut, and most often nearer the size of a large pea, while they are commonly multiple. While there has been a good deal of controversy, and some inconclusive experimentation, as to the producing cause of the diverticula, they are probably due to the pressure of contained feces acting at points of diminished muscular strength. That pressure is really the active cause seems to be shown by the fact that in some cases the diverticulum is merely a protrusion of the mucous through the muscular coat of the gut, while in others all the coats take part in its formation. It is obvious that a diverticulum of the intestine may give rise to pathological conditions of very various nature, of great importance, and of difficult diagnosis. Since the wall of the diverticulum is thinner than the normal wall of the gut, it is, of course, easy for inflammatory conditions to spread to the peritoneum, and many such cases have been recorded. Dr. Edwin Beer, of New York, who has made an exhaustive examination (a) of the literature of the subject, emphasises the frequency with which such inflammations have been mistaken for malignant disease, the error occurring even on the operating table. Among the other complications he has noted are stenosis of the gut, perforation into the peritoneum, abscess, and fistula leading into the bladder.

#### PERSONAL.

THE Marquis of Ripon, as Chancellor of the University of Leeds, will inaugurate the first full session of that body at the forthcoming graduation ceremony on October 6th.

THE proceedings of the National Temperance League

(a) *Amer. Journ. Med. Sci.*, July, 1904.

at Oxford promise this year to be of unusual interest. The annual Association meeting breakfast on the 28th will be presided over by Mr. McAdam Eccles.

GOLF-PLAYING members of the medical profession at the Oxford meeting should note the address of Dr. Proudfoot, 43 St. Giles, Oxford, who has charge of the golfing arrangements. There is an excellent course about four miles from the city.

PRINCIPAL LANG presided at the recent meeting of the University Court, which discussed the formal proposals for the quarter-centenary celebration of the University of Aberdeen, which will occur in 1906.

It was practically agreed by the Aberdeen Court to defer the proposed installation of Lord Strathcona and Mount Royal until the year following that of the quarter-centenary.

DR. BURGEN, of Montreal, has been elected President of the American Medico-Psychological Society, said to be the oldest medical society in America.

DR. BURT, of Ontario, has been elected President for 1905 of the Ontario Medical Association.

LORD STRATHCONA has presented 20,000 dollars to the University of Manitoba, the sum to be expended on the Science Department of the University.

We offer our congratulations to Dr. Kendal Franks on the honour of knighthood conferred on him last week by the King. He formerly occupied a leading position in Dublin medical circles, and was Surgeon-in-Ordinary to the Viceroy of Ireland. Ill-health, however, caused him to resign his various appointments, and to seek the more congenial climate of the Cape. During the South African War he was appointed Consulting Surgeon to His Majesty's Forces.

THE Home Secretary has appointed Mr. Clinton Thomas Dent, F.R.C.S., to the post of Chief Surgeon to the Metropolitan Police, rendered vacant by the death of Mr. A. O. McKellar.

THE Empress-Dowager of China has presented ten thousand taels towards the new Medical College and Hospital now building in Peking.

ON the occasion of the recent visit of the Bristol Health Department to Dartmouth, an interesting presentation was made to Dr. D. S. Davies, the well known and popular Medical Officer of Health of the first-mentioned town. The presentation took the form of a handsome silver salver.

### Special Correspondence.

[FROM OUR OWN CORRESPONDENT.]

#### SCOTLAND.

*Care of Imbecile Children.*—The Medical Committee of the Edinburgh Parish Council are considering the advisability of providing a home at the new Bangor Asylum for the imbecile children of the city. At present those who have to deal with these most melancholy cases are too well aware of the great difficulty of inducing the parochial authorities to do anything for them—and this is not unnatural, for, unless the parents are in a position to pay a very considerable sum towards their support, the cost to the parish in maintaining them in such institutions as Larbert is very great. Added to this is the fact that accommodation for imbeciles at the lowest scale of charges, which is all that the parochial authorities can pay, is very limited, and practically it results that the majority of imbeciles in the parish must remain at home, a trial to their families and deprived of even the slight prospect of improvement which suitable institutional treatment

affords. It is much to be hoped that the Parish Council will make some provision for these patients, and thus relieve the parents of one of the cruellest burdens which can afflict the poor.

*Graduation Ceremonial at Edinburgh University.*—The University Session was definitely brought to an end on Saturday by the usual autumn graduation ceremony in the McEwan Hall. The honorary degree of LL.D. was conferred on Emeritus Professor Butcher, who so recently resigned the chair of Greek in this university, on Sir Walter Hely-Hutchinson, Mr. John Morley, M.P., Sir George Reid, ex-president of the Royal Scottish Academy, and Professor William Thompson, Registrar of the Cape University. Thereafter the ordinary degrees in medicine and science were granted, and the prizes distributed. The graduates were then addressed by Professor Cunningham, the text of his remarks being the evolution of the graduation ceremonial. The office of Promoter for the year (as the professor who introduces the graduates is called) is one of great antiquity, going back, as it does, to the earliest period of university life. The symbolic part of the ceremony is a survival of earlier times, but represents only a small part of the imposing display which accompanied the conferring of degrees in the Middle Ages. In those days preparations were made for days before the ceremony took place, and on the day of the ceremony a general holiday was observed. Rector, Promoter, masters, doctors, and masters in arts, all with their insignia, took part in a solemn procession to the cathedral, accompanied by the noise of drums and trumpets. In the majority of universities not more than one candidate was publicly promoted to the degree of master or doctor in the year, the heavy cost rendering graduation for these degrees somewhat rare occurrences. In only a few of the modern European universities has much of the old graduation ritual been preserved; in France there is practically no ceremonial; in Germany too, it has been abandoned. The ancient ritual is retained more or less intact in the Papal University of Rome, as also in Spain; and in Coimbra (Portugal) the ceremonial survives in its purest form. Little or nothing of the old ceremonial survives in Oxford or Cambridge. In former days the new graduate, among other ceremonies, had to receive the kiss of peace not only from the Promoter and the Chancellor, but also from the other doctors and masters present. Lady graduates of to-day will heave a sigh of relief to learn that only a small part of the ancient customs now survive in Edinburgh. The velvet cap placed on the head of candidates is the principal surviving characteristic; it is the sign of liberty, and originally meant the emancipation of the new doctor from the thralldom and subjection of the pupillary period.

*Edinburgh Simpson Memorial Maternity Hospital.*—The directors have appointed Dr. Lamond Lackie and Dr. H. Oliphant Nicholson to be Assistant Physicians to that institution. Both gentlemen are well known in Edinburgh and their appointments are cordially welcomed.

## British Medical Association.

[BY OUR SPECIAL MEDICAL REPORTER.]

THE SEVENTY-SECOND ANNUAL MEETING OF THE BRITISH MEDICAL ASSOCIATION IS BEING HELD THIS WEEK AT OXFORD, FROM TUESDAY TO FRIDAY, JULY 26TH TO 29TH.

It is peculiarly fitting that representatives of British medicine should congregate in one of our most ancient seats of learning, rich in its inheritance from out the long-storied past. Oxford has done much for the advancement of physic, and not a few practitioners of the healing art have brought distinction and renown to their Alma Mater. The University may well be proud of its association with medicine. Its graduates from the twelfth century till now have been eminent in their profession, and many benefactions have come to the city through the life and work of her physicians.

Oxford will do well to keep in mind the names of her illustrious medicals. The many visitors to Oxford will find inexhaustible stores of delight in its ancient colleges and peaceful pleasaunces; its ever attractive river and glorious countryside; and when it is remembered that extensive preparations have been made for an open-handed hospitality it may well be that the purely scientific work of the meeting will be maintained chiefly by the enthusiasts and progressives of the Association.

### THE NEW PRESIDENT.

DR. WILLIAM COLLIER is well fitted, both by personal characteristics and professional position, to fill worthily the Presidential Chair of the British Medical Association.

Dr. Collier was educated at Sherborne and Jesus College, Cambridge, and proceeded to his M.A. in 1881. As an athletic blue he competed in the Inter-University sports in "the mile" and the "three mile" during three seasons of 1875-78. In the latter year he entered King's College Hospital, and took his M.R.C.S. and L.S.A. in 1880. In 1881 he graduated M.B. of Cambridge, and in 1885 took his M.D.

He is well acquainted with the details of hospital work, having held resident appointments at Addenbrooke's Hospital, Cambridge, Wolverhampton General Hospital, and the Radcliffe Infirmary, Oxford. In 1885 he was elected Hon. Physician to the latter.

In 1886 he took the Membership of the College of Physicians and in 1892 was elected a Fellow.

Dr. Collier is also an M.A. of Oxford. He is now Litchfield Clinical Lecturer, and holds other important positions. He is also a member of various learned societies, and has contributed several important articles to medical literature, the best known of which deal with problems connected with cardiac affections.

Dr. Collier occupies a unique position as head of the great body of associated medical practitioners in Great Britain, and may be trusted to sustain the dignity

and to extend the influence of the Presidentship of the British Medical Association.

#### RELIGIOUS SERVICES.

Remembering the close association of divinity and physic in our schools, and religion and the healing art in daily life, it is peculiarly fitting that religious services should mark the annual gathering of medical practitioners. On Tuesday morning, services were held in Christ Church Cathedral and St. Aloysius Catholic Church. This morning services are being conducted in Mansfield College Chapel and at Manchester College.

#### GENERAL ARRANGEMENTS AND REPRESENTATIVE MEETINGS.

The organisers have been at much pains to arrange everything for the comfort and convenience of the visitors. The reception room is in the Examination Schools in the High Street, where also the general and representative meetings are to be held. The general addresses are to be delivered in the Sheldonian Theatre. The sections will conduct their work in the various departments of the University Museum, with the exception of the Sections of Ophthalmology and Dental Surgery, which will be held in Keble College. The "doings" of the day are conveniently defined in the "Daily Journal." The stranger will find much of interest in the excellent handbook to Oxford.

The address of the President, Dr. William Collier, was given last evening before a large and representative audience. The reception of distinguished guests was a feature of much interest. The adoption of academic costume on this and other occasions does much to brighten the festive scene, and it is thought that mere male millinery will not prove prejudicial to the scientific sense of the gatherings. Sir William Church gives the Address in Medicine this evening, and to-morrow afternoon Sir William MacEwen the Address in Surgery.

#### THE WORK OF THE SECTIONS.

Amidst the numerous attractions of the annual gathering it is particularly desirable that no pains should be spared to maintain the scientific work of the proceedings. This year, although no epoch-making discovery may be announced, or great departure in practice be initiated, it seems probable that a high level of excellence in the work of the fourteen sections may be attained. By a wise arrangement, special discussions have been announced, and in many instances abstracts of the introductory papers have appeared in the Association's official publication.

In the Section of Medicine, a consideration of the treatment of tuberculous pleural effusion and pneumothorax will be introduced by Professor W. Osler, of Baltimore. The serum treatment of disease and the management of chronic Bright's disease will also furnish much material for discussion.

Surgeons will be interested in the discussion on the present aspects of a sepsis and antiseptics; and the indications for, and methods of, performing hysterectomy should give rise to a free expression of opinion.

All the Sections have prepared attractive programmes of papers, many of which will doubtless do much to advance our knowledge of the subjects with which they deal. We hope to refer to the more important discussions and papers in our next issue, and we shall publish abstracts of some of the more important of the communications.

#### THE PATHOLOGICAL MUSEUM.

This year a praiseworthy attempt has been made to present as far as possible the results of recent investigations in medical science. The collection is arranged in the large, well-lighted, readily accessible ground-floor rooms of the Anatomical Department. We understand exhibitors are to be given an opportunity of personally demonstrating their specimens or apparatus at definite times. Among the more important exhibits are specimens of ankylostomiasis, miners' lung disease, diseases of tropical climates, and preparations illustrating congenital dislocation of the hip before and after treatment by Lorenz's method, the estimation of the phagocytic power of the blood, and the detection of purin bodies in the urine. General satisfaction is

given by the museum being kept entirely distinct from the trade exhibits.

#### THE EXHIBITION.

A collection of medical, surgical, dietetic, and sanitary apparatus, medical books, and hospital appliances has been brought together in the Examination School, in the same building as the reception room. Much difference of opinion exists as to the wisdom of providing for a trade exhibit under the auspices of the Association, but while much can doubtless be said in favour of discounting such an alliance on the grounds of expediency, reasons can be adduced for its retention. Most of the leading medical publishers have, however, abstained from exhibiting.

#### ENTERTAINMENTS AND EXCURSIONS.

While the scientific work of the Association must ever be accorded first place, it is well that the more festive features of the week should not be allowed to lapse, and this has evidently been the opinion of the Oxford Committee, who have prepared a very attractive programme of entertainments and excursions. The annual dinner will be held in Christ Church Hall on Thursday evening. On Thursday afternoon an international golf match is to take place.

#### SPECIAL MEETINGS.

The annual assembly is wisely made an opportunity for holding other meetings at which matters intimately concerned with medicine or pertaining to the work of medical practitioners may be discussed. This year several important gatherings have been arranged for. The annual medical temperance breakfast is to be held in the Town Hall on Thursday morning, presided over by Mr. McAdam Eccles, who will be supported by the President, Sir William Broadbent, Sir Thomas Barlow, Sir Victor Horsley, and other leaders of the profession. The forty-fifth annual meeting of the New Sydenham Society is to be held on Friday, July 29th, at 9.30 a.m. The annual luncheon of the Continental-Anglo-American Medical Society is to be held at the Clarendon Hotel on Thursday, at 1 p.m.

## Correspondence.

[We do not hold ourselves responsible for the opinions of our Correspondents].

#### THE DIMINISHING BIRTH-RATE.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—My two critics to some extent answer each other. My thanks are due to Dr. Drysdale for dealing with the first part of Dr. Walsh's paper.

If the chief advocates or apologists of "prevention," as well as its chief opponents, are both agreed that the diminishing birth-rate is due mainly (in the words of Dr. Billings) to "the deliberate and voluntary prevention of child-bearing on the part of a steadily increasing number of married people, who not only prefer to have few children but know how to attain that wish," we need not trouble ourselves much either with technical errors of classification or with a long and wordy discussion on subsidiary causes recognised as such by myself as well as by my critics. Dr. Walsh may be technically right in the method employed by him for computing the birth-rate, but with all his ingenuity he cannot turn a "minus" into a "plus," and in using it he falls into a far greater fallacy than any he thinks he is exposing. For we have increasing evidence that the habit of "prevention" is not, as I hoped, confined to married life and prostitution, but is becoming more and more used by the unmarried, and this, rather than any moral improvement, may account, and probably does account, for much of the decrease in illegitimate births. This practically disposes of the first twelve of Dr. Walsh's so-called conclusions.

Dr. Walsh's later conclusions cover more debatable ground, containing, as they do, references to one of the most important points of the controversy—*viz.*, the quality as well as the quantity of the children born to the nation. This I have dealt with as far as I could, not by assumption but by records of fact. The only possible

justification for the following of so unnatural a practice as that of sexual congress habitually adjusted to a certainty of imperfection would lie in a great benefit accruing to posterity, or, in other words, in the greater value of the population after being subject to such restriction. This "greater value" is now shown to be non-existent. There may be diversity of opinion as to how this result is produced, but there can be little question of the fact. Instead of a greater value we find a lessening value—a deterioration in quality as well as a limitation in quantity—and I search in vain in the writings of my critics for anything but vague questionings to disprove what I have advanced regarding this decadency.

Most of my critics, and especially Mr. Wells and Dr. Walsh, take a far too narrow and imperfect view of evolution. They appear to assume that the process is one of continuous advance for all nations and times. They lose sight of the ebb as well as the flow of progress. They seem to forget the records of history, the vast periods of national decadence and slow destruction, on which and through which we have slowly climbed to our present position. They have not adequately recognised the moral basis on which national greatness rests. And it is small comfort, I submit, to the twentieth century Englishman to know that the human may still develop in power and energy if such development must rest on the ruins of the Empire which his fathers made. The late Dr. Engelmann of Boston, wrote as follows, in 1903, (a) and I agree with him:—

"The factors are the same which have been active in earlier civilisations as they are to-day. Increasing wealth and the introduction of foreign manners are pointed out as causing in ancient Rome the lessening fertility among the better classes which preceded political disruption. Cause and effect were the same, and even the methods employed to thwart the tendencies of Nature were the same:—

"Sed jacet aurato vix ulla puerpera lecto

Tantum artes hujus, tantum medicamina possunt,  
Quæ steriles facit, atque homines in ventre necandos  
Conducit."

(Juvenal: Sat. vi., 594-7.) (b)

Both of my critics bring forward the old fallacy that there is no room in the United Kingdom for a larger population. There may be no room for the drugged neurotic, the lunatic, and the youthful criminal—the very classes we are increasing in some way by "prevention"; there is always room for the healthy-minded, the pure, the worker, and the brave. At what period, I would like to ask, were the old-world cities of Tyre and Sidon too small for the Phœnicians, who had founded their prosperity? Was it not at the time of their greatest power and influence when the Phœnicians were sweeping the Mediterranean with their commerce and establishing their colonies in Asia Minor, in Cyprus, in Greece, in Africa, in Crete, in Sardinia, in Spain, and even in England?

If the United Kingdom is too small, the British Empire is not. Large continents with inexhaustible lands under our protection or influence are crying out for capable colonists, not for the two children of the "prevented" family, who will never be fit to leave their mother's leading-strings, but for such men and women as made the Empire from Elizabeth to Victoria, men and women who are manœuvred out of existence by the wickedness of to-day.

Dr. Walsh suggests that the cause and effects of the diminishing birth-rate may be best ascertained by a Royal Commission of Inquiry.

Does he not know that a Royal Commission was appointed by the New South Wales Government in August, 1903, to consider and report upon the serious decline in the birth-rate, and that their report, published one month after my address, bears out in a striking

degree every word that I have said on this subject? I take the following from the *Australasian Medical Gazette*, of March 21st, 1904:—

"We consider the report (of the Royal Commission) a masterpiece of exhaustive examination and investigation of a subject which, it is admitted on all hands, bristles with difficulties. The Commissioners have found as a result of their investigations that the decline of the birth-rate is due in very large measure, not to any physical degeneration or lack of fertility in the present generation of Australian women, but to deliberate checking of the procreation of children by various artificial methods, thus nullifying one of the main objects of marriage and degrading the married state from one of honour to that of "monogynous prostitution."

The Commissioners are also most emphatic in their conclusions that the adoption of these practices for the limitation of families tends to the physical and moral degeneration of the race. They point out that the increase of insanity is going *pari passu* with the decline in the birth-rate; and there can be no doubt that a very large amount of ovarian and uterine disease is to be attributed to the use of various instruments which are used to prevent conception, but which favour sepsis and thus predispose to chronic disease of the uterus and its annexa."

Dr. Walsh has appealed to a Royal Commission; to this Royal Commission I refer him, asking him to note that through the whole of my indictment I have striven to be fair and sympathetic, and that nowhere in my writing will he find any expression so deliberately offensive as this of "monogynous prostitution."

But I have something more to say, Sir, to Dr. Walsh and to others of the profession who are rightly interested in this important subject. The evil exposed by the Royal Commission is not now confined to married life. It is spreading, as I have already pointed out, to the young and single, and the statistics of illegitimate births have no longer any necessary definite bearing on morality. Why should the bond of marriage, the new generation is asking, be the necessary precursor to sexual life when there need be no danger of pregnancy?

My tongue is tied by the confessions of my patients, but I do not care to be the deposit of shameful secrets without publicly entering my protest and declaring my belief that the so-called civilisation which spreads the knowledge of "artifices for making women sterile" in almost every house and practically encourages the living lie of a secret immorality in the unmarried sisters and daughters of our country is decadent and corrupt. Unless it can be cleansed and purified it cannot last, and deserves to be swept away as other civilisations have gone down before it.

But is it too late to alter?

I am, Sir, yours truly,

JOHN W. TAYLOR.

22 Newhall Street, Birmingham, July 22nd, 1904.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR.—Dr. Walsh seems to dispute the statement that the diminishing birth-rate can be due to the artificial sterility of married couples. The effect of this cause is, however, recognised by his equals in scientific authority. I have before me the English version of the recently published great work by Professor Metchnikoff, of the Pasteur Institute, "The Nature of Man," edited by Dr. P. Chalmers Mitchell. In an introduction the editor writes: "Metchnikoff is an expert of experts in the science of life, and has gained the right to a hearing by forty years of patient devotion and brilliant research." At page 101, Metchnikoff writes: "To the human race belongs the distinction of having invented modes of sexual congress which are necessarily barren. . . . There are many ways in which the spermatozoa may be prevented from accomplishing their function, and these are so common and so familiar that it is unnecessary to enumerate them. In civilised countries procreation is limited chiefly by such means."

(a) "Cause of Race Decline." *Popular Science Monthly*

(b) TRALS.—"Few children are born in the gilded bed to the wealthy dame, so many artifices has she, and so many drugs to render women sterile and destroy life within the womb."

After discussing the practice of artificial abortion and infanticide among primitive races, the author (page 105) remarks: "In more highly civilised nations, the rude proceedings of savages have been replaced by clever devices to prevent conception, and infanticide has become rare. Artificial abortion is excited by modern methods suggested by the progress of science. The embryonic membranes are pierced not by ribs of seals or hairpins, but by sterilised sounds, and the operation is performed with strict asepsis. In averting the natural results of passion the woman is subjected to the smallest possible risk. It is indubitable that more than one race has perished because of its lack of the instinct of family. . . . It is plain that the readiness with which devices to prevent the production of children have been adopted shows the weakness of the family instinct in man, and opens up a problem to which the attention of moralists and legislators may well be directed."

It is necessary only to read French works on social problems and fiction, and to mingle in French society of different classes, to learn at first hand the fact as to the almost universal practice among married couples of limiting the offspring to a number previously agreed upon. No secret is made of this custom, nor is any shame ascribed to it. It is discussed freely in family council by parents and betrothed couples, although delicate details may not be entered into before an ingenuous maiden. This fact is very well brought out in a recently published little book which, although composed in lighter vein, deserves and has received praise from serious reviewers. The book in question is styled "My French Friends." It is written by a lady who shows a complete knowledge of French life and social customs. The question of limiting the number of children is referred to over and over again in conversation on the subject of marriage, and no doubt is left as to the custom which prevails. French parents would consider it barbarous and cruel to bring into the world a number of children whose future they could not provide for. The provision of a suitable *dot* for the girl is the first consideration. As one of the characters, a model French mother as well as an intellectual woman of the world, remarks: "Happily the problem of six or ten children in the family which can only provide suitably for two or three, is not one we often give ourselves to solve here in France, but in all cases the future of the girl is regarded as of equal importance with that of the son."

The application of these ideas saves boys in great part from the fight in life without which fine manly character can rarely be attained, and makes of the girl a wife and mother, however ill-suited she be for this *rôle*.

I venture to affirm that not a particle of scientific evidence has ever been adduced to prove that progressive civilisation leads to the evolution of an infertile type. On the other hand, the evidence is overwhelming that the stagnation of population in France, allowing for the effects of late marriages and large preventable infantile mortality, is due mainly to the artificial prevention of conception practised by the great bulk of married couples.

On numerous occasions when you have allowed me to enter into the discussion of this subject, I have given the reasons for the belief that a nation which becomes imbued with the form of narrow egoism which constitutes the foundation of the custom almost universal in France, is doomed to gradual decay and destruction; and I need not repeat those reasons now. Finally, I believe that the diminishing birth-rate in this country is very largely due to the adoption in late years of French ideas and practices, and that the resulting ill-effects upon the moral fibre of large sections of the people are already discernible to close observation.

I am, Sir, yours truly,  
A STUDENT OF SOCIOLOGY.

#### SOME OF THE NEWER METHODS OF OPENING AND CLOSING THE ABDOMEN.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.  
SIR,—The plan of closing skin wounds in the abdo-

minal wall, which Dr. Hastings Tweedy describes in your last issue and appears to consider "so far as he knows, is novel," is in reality nothing more or less than an adaptation of Nathaniel Bozeman's well-known "button suture," formed of leaden discs, which proved so successful in his hands nearly a quarter of a century ago in the treatment of vesico-vaginal fistulæ!

Dr. Tweedy states that the suture he uses is left in "for fourteen days," and then cut. I am under the impression that cutting would hardly be required if silk-worm-gut sutures were left so long imbedded in the tissues; perhaps he may mean that part of suture tied over leaden plate. Dr. Nathan Bozeman, the designer of this form of suture, from whom I hold a letter on the subject, also considered the leaden plate had some influence on the healing; I should imagine by its equable pressure, and by preventing movement of the parts and cutting also. The idea of a perforated leaden plate as a splint for the cut surface is not novel, but, as we would say nowadays, ancient history.

I am, Sir, yours truly,  
ALEXANDER DUKE.

#### OUR "DAILIES."

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—It is probable that some of us, when looking through one of the "dailies" and finding the report of some medical conference or society, cannot help thinking how different it was years ago, when such subjects would have been thought proper only in one of our own journals. Science is now fashionable, and it is natural that those who are interested in social questions, into which medical science enters more or less forcibly, should read with attention the report of a discussion upon any subject that has relation to the wide and important one of public health. Health and wealth are so closely associated that we cannot afford to neglect the one without loss of the other. When matters medical are introduced to the public through our "dailies," or other non-professional journals, it is necessary to make some allowance for the difficulties of giving those who have no knowledge of medical science correct and clear ideas of the questions discussed, and of the conclusions at which well-educated members of the profession arrive when dealing with some new theory or discovery, particularly when such is subversive of the views or doctrines they have held and believed in before. We hope now to consider somewhat carefully the work that is being carried on by the society engaged in the research into the origin, nature, and treatment of cancer. This disease is one of those that can be traced back to almost prehistoric times, and it seems as if the difficulties of solving the question of its origin are now greater than ever. We are deeply impressed with the importance of looking more to the prevention than to the cure of cancer, particularly when we see how this is necessary in the interests of public health. No class, of course, takes precedence of infectious diseases, or at least none that requires more carefully to be considered by our Legislature. As cancer does not belong to this class it is probable that its treatment will be of far greater interest than research into its origin, and we must be careful lest we indulge too much in hopes that may be held out to us by those who are clever enough to take advantage of poor humanity.

In the report of one of our leading "dailies" of the third meeting of the General Committee of the Cancer Research Fund, it is stated that: "The public and the medical profession are, therefore, gravely warned not to delay to take advantage of the surgeon's aid in the hope that some means will speedily be found to replace surgical interference." If any non-professional understands this we must say we should feel some surprise, for how anyone could fly to the surgeon in the hope that that is the best way to do without him is difficult to understand. The public and the profession are both treated as innocent and ignorant questionists of the nature and treatment of cancer. "The report contained one weighty warning. No sign has yet been

discovered by which the physician or surgeon may surely recognise the presence of cancer." Some of our readers may agree with this opinion, and some may not. We are rather inclined to think that no one is more likely to be correct in the diagnosis of cancer than the physician or surgeon who has given up his life to the clinical study of disease. It is not likely that those who have done nothing but work with the microscope and in the laboratory can have any idea of the kind of knowledge obtained by clinical study; and if the Cancer Research Society is going to assume a superiority over the profession and warn it and the public through the "dailies" in the tone of the report from which the above extracts were made, we think it well in the interests of the public first, and next in that of clinical medicine and new students, to warn them, the public and the profession, against the warnings of a society that works in such an illogical and unscientific spirit. As far as we can make out there is nothing left now, according to the report of the Cancer Research Fund, but for the poor public to rush off to the surgeons to operate for fear of cancer, and to be kept in most painful suspense till the end of life is near and the difficulties of diagnosis are settled.

I am, Sir, yours truly, R. L.

#### CENTRAL MIDWIVES' BOARD AGAIN.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Your excellent leader on the Midwives' Board's "sheer stupidity and egregious performances" appeals to every sensible member of the profession. The attempted levelling down of the doctors to the position of man-midwife seems like going back a century. No wonder you pertinently ask, "Whence have the nursing profession of the day obtained this knowledge in training, except from the hands of medical men?" some of whom apparently have for years made a "good thing" out of it; and perhaps the knowledge of this fact impels some such to the further exaltation of the midwife and the depreciation of the medical man. Is it likely the midwife, recognising her power, will play second fiddle to the most experienced practitioner, unless compelled by risk of losing her patient, to ask his help? Dr. Ward Cousins deserves thanks for voicing the profession, "who feel strongly on the point," and the matter cannot be allowed to rest, nor Dr. Cullingworth's eminence save him from censure by thus lowering his own profession.

I am, Sir, yours truly,

A. D.

#### Obituary.

ARTHUR K. CROSSFIELD, L.R.C.S., L.R.C.P.ED., J.P., DARTMOUTH.

MR. ARTHUR KYFFIN CROSSFIELD died recently at his residence, Dartmouth, after a short illness, from appendicitis. The deceased, who was in his fifty-second year, was the son of the late Mr. R. Crossfield, of Douglas, Isle of Man. He was educated in Edinburgh, and took the qualifications of L.R.C.P., L.R.C.S., L.M. Edin., in 1878. After holding a resident appointment at the Isle of Man, he commenced practice at Dartmouth. He took great interest in the volunteer movement, was surgeon-lieutenant-colonel in the 2nd Devon Royal Garrison Artillery Volunteers. Mr. Crossfield was a Justice of the Peace for the borough of Clifton-Dartmouth-Hardness. His loss will be felt among a wide circle of friends.

SIR JOHN SIMON, K.C.B., M.D. DUB., F.R.S. F.R.C.S., LL.D., OXON. LL.D. CANTAB.

We regret to announce the death of Sir John Simon, K.C.B., on Saturday, the 23rd inst., at his residence in Kensington. Born in 1816, he became an Honorary Fellow of the Royal College of Surgeons in 1844, and was the first appointed Officer of Health to the City of London in 1848. For many years he acted as Surgeon to St. Thomas's Hospital. From 1855 to 1876 he was Medical Officer to the Board of Health, to the Privy Council, and to the Local Government Board. He was the author of several papers on physiology, pathology,

and surgery, and of reports and other official papers relating to the sanitary state of the people of England. The University of Munich, at its 400th anniversary, in 1872, conferred upon him the honorary diploma of Doctor of Medicine. So far as his scientific work was concerned, he may be regarded as one of the great pioneers in State medicine, and the series of official Reports issued under his presidency are models of classical style and valuable records of original investigation. He was made a C.B. in 1876 and a K.C.B. in 1887, and was one of the Crown members of the General Medical Council. In 1878 he was elected President of the Royal College of Surgeons, and in 1879 of the Royal Society.

#### Literature.

##### HYDROTHERAPY. (a)

THE speedy appearance of a second edition affords the surest proof that the first issue has been approved, and certainly in the present case Dr. Baruch's excellent treatise on the therapeutic and hygienic uses of water well merits the appreciation it has received. The new edition has been thoroughly revised and brought up-to-date, and much new matter has been added. The work still retains its former aspect. The principles of hydrotherapy are first discussed, and then follow details regarding methods and particulars concerning application in special diseases. In the new edition a chapter on reaction affords much valuable material as to the physiological basis of hydrotherapy. A chapter on insanity has also been added, and in it the wisdom of a rational application of water as an alleviating agent is clearly indicated.

The work is written in a judicial and scientific spirit, although full of the energy of the enthusiast. The author is anxious to place the practice of hydrotherapy on a sound and rational basis, and we venture to think his effort should go far to divorce it from the slipshod, inexact, and quackish procedures which only too widely prevail in so-called hydropathic establishments.

Dr. Baruch may be congratulated on having produced a book which has found favour in all English-speaking countries, and which is likely to influence beneficially hydrotherapeutic practice in both America and Europe.

##### NOBLE SMITH ON LATERAL CURVATURE. (b)

THIS is a short but practical treatise on the treatment of what usually proves to be a very intractable condition. The author points out that in the treatment of spinal curvature the real cause of the deformity is inefficient nutrition of the various structures of the body. This results in softening of the bones so that lateral curvature is produced. He describes a number of exercises with a view to correcting the abnormal curves, and especially to overcome spinal rotation which is usually present in these cases. With regard to massage, the author states that it must not be applied indiscriminately, and that in the majority of cases it is quite unnecessary. He then goes on to describe the use of a special splint which he claims is of great value in the treatment of lateral curvature. It has the effect of supporting the patient's back, and yet allowing of perfect freedom of muscular movement.

The second portion of the book deals with the management of stooping, round shoulders, and kyphosis. The effects of clothing in the production of these conditions are clearly pointed out. Regarding the much-talked-of corset, he says that there is no great harm in its use so long as it leaves the thorax free from pressure. A series of very simple exercises for the correction of stooping is given, and the special splint already referred to is once more recommended. The

(a) "The Principles and Practice of Hydrotherapy. a Guide to the Application of Water in Disease. For Students and Practitioners of Medicine." By Simon Baruch, M.D., Professor of Hydrotherapeutics in the New York Post-Graduate Medical School and Hospital, &c. Second Edition, revised and enlarged. Pp. 496 and 74 figs. Price 76s. net. London: Bailliere, Tindall and Cox, 1904.

(b) "The Management of Lateral Curvature of the Spine, Stooping and the Development of the Chest in Phthisis." By E. Noble Smith, F.R.C.S. Edin., &c., Senior Surgeon to the City Orthopaedic Hospital, London. Pp. viii., 133. Price 2s. 6d. London: Smith Elder and Co. 1904.

book concludes with two suggestive chapters on the influence of diet upon physical development, and on the development of the chest in respiratory affections.

The author writes in a spirit of hopefulness regarding the lines of treatment advocated, and certainly his suggestions are worthy of careful trial. We can heartily commend this short treatise to those interested in the physical development of children. It is undoubtedly a valuable contribution to the literature of this important subject.

#### ROLLESTON'S CLINICAL LECTURES AND ESSAYS. (a)

THIS is a collection of seventeen lectures and papers on a variety of medical subjects, which have been reprinted with certain additions from the various journals in which they originally appeared. The opening lecture on "Vomiting in Diphtheria" is most instructive, as is also that on the "Treatment of Typhoid Fever." We are glad to renew our acquaintance with the case of persistent hereditary oedema which the author brought to the notice of the profession a short time ago. The account given of the case of Recklinghausen's disease is extremely interesting, as is also the description of the necropsy which the author was fortunate to obtain. The paper, entitled "Some Remarks on the Uses and Abuses of Arsenic" is full of valuable information, and will well repay careful study.

Taken as a whole, the topics dealt with in this volume are of interest to the general practitioner, while those who delight in the anomalies of clinical medicine will find within its pages much to ponder over. We think Dr. Rolleston is to be congratulated on having such a rich store of clinical material at his disposal, and on his extremely facile language in describing the conditions referred to in this collection.

#### MANN ON THE PHYSIOLOGY AND PATHOLOGY OF THE URINE. (b)

IN this excellent, though short work, the author endeavours to place before his reader the latest survey of those branches of biological chemistry which are connected with the physiology and pathology of the urine. Though the book is primarily intended as a clinical guide and chief prominence is given to methods of examination which can be carried out in the clinical laboratory, many other processes which are beyond the scope of a clinical laboratory are also described in order to prove of help to investigators "who desire to carry their researches further."

The book is most systematic in its arrangement. Commencing with a description of the general characteristics of urine, it next discusses the different urinary inorganic and organic constituents, the amido and aromatic acids, carbohydrates, proteids and nitrogenous substances, pigments, and bile acids. The special characteristics of urine are then discussed, as well as urinary sediments, and calculi, the volume ending with a section devoted to the study of urine in its pathological relations. The book is well and clearly written, and we can cordially recommend it to any one who possesses a fair knowledge of medical chemistry, and who is desirous of entering more fully into the special branch of the physiology and pathology of the urine.

#### THE NEW SYDENHAM SOCIETY ATLAS OF ILLUSTRATIONS. (c)

THE new Fasciculus of this beautiful Atlas deals with

(a) "Clinical Lectures and Essays on Abdominal and other Subjects." By H. D. Rolleston, M.A., M.D., Cantab., F.R.C.P., Physician to St. George's Hospital, &c. Pp. 178. Price 5s. net. London: Sidney Appleton, 1904.

(b) "Physiology and Pathology of the Urine with Methods of Examination." By J. Dixon Mann, M.D., F.R.C.P., Physician to the Salford Royal Hospital, Professor of Forensic Medicine in the Victoria University of Manchester. London: Charles Griffin and Co. Pp. xi. and 272, and several illustrations. 1904.

(c) "An Atlas of Illustrations of Clinical Medicine, Surgery, and Pathology, compiled for the New Sydenham Society." Fasciculus XVIII (Double Fasciculus), being VII and IX of the Clinical Atlas. Eruptions, &c., caused by Arsenic, Urticaria Pigmentosa, Illustrations of the Phenomena of Leprosy. London: The New Sydenham Society. Agent, H. K. Lewis, 1903.

three subjects—arsenical poisoning, urticaria pigmentosa, and leprosy. The fasciculus is a double one and contains a large number of original plates, including seven reproduced from photographs taken during the epidemic of poisoning by arsenic in Manchester in 1901. There are some especially good chromo-lithographs of the rare condition, urticaria pigmentosa. Each article is prefaced by very full introductory remarks on the different subjects by the Editor, and altogether the present number is well up to the standard that has been set by its predecessors.

#### ST. BARTHOLOMEW'S HOSPITAL REPORTS. (a)

IN the space at our disposal, we can do no more than direct the reader's attention to the wealth of information this Report contains. The volume opens with an In Memoriam notice, W. J. Walsham, which tells of the combination of genius and industry with an unfortunately delicate health. The writer tells the story with the sympathy and love of one who was both a pupil and a friend. The special features of the number are, however, the article of Dr. J. Graham Forbes, "Medical Report of the Anglo-French Boundary Commission on the Western Frontier of the Gold Coast Colony," which occupies eighteen pages and is beautifully illustrated with photographs. This is followed by a second article by the same author, "Native Methods of Treatment in West Africa," and Dr. Weber's paper "Action and Reaction in Pathology and Therapeutics." Turning to the ever-interesting statistics of anaesthetics, we find that chloroform alone was administered 2,847 times, ether alone 181 times. There were seven casualties, of which detailed accounts are given. We regret that we cannot give space to quotations of some length from Dr. Forbes' article on native treatment. We must, however, refer to the Rotunda, or, as some will say, Crédé's, method of pressing out the placenta, which has been practised for centuries on the Gold Coast. "The placenta is expressed immediately after the birth of the child," and a little further on we read that "Turning by abdominal palpation and moulding is practised when the child lies 'across the belly' to make the head or foot come first, either of which means of delivery is considered equally good." Aseptic precautions appear to be the rule, for the author says "No attempt for any reason is made to introduce the fingers into the vagina."

#### STEVENSON'S WOUNDS IN WAR. (b)

THE second edition of this excellent book will be welcome to all interested in military surgery. It is full of original and accurate information, and since the appearance of the first edition in 1897, the author has been able to draw from the rich store of experiences accumulated in the Boer War and those recorded in the statistics of the Spanish-American War. The systematic and detailed description of the various injuries due to projectiles and to hand-weapons involves a great amount of special information, just as the treatment of that class of wounds on the field demands a practical acquaintance with the conditions of campaigning. The civil surgeon will find this book full of interesting and suggestive material. The grazing of arteries, for instance, by bullets of high velocity gave rise to many of the "varicose aneurysms and aneurysmal varices that have been a remarkable feature of the surgery of the Boer War." In that campaign, again, it was for a short time supposed that the men were using poisoned bullets. A newspaper scare at the time was silenced only by the discovery that the supposed poison was nothing more than verdigris from the paraffin used for lubricating the copper cartridge cases. Many of the illustrations are new and illuminating. The skiagrams are for the most part excellent specimens taken in the Boer war. In wounds of the hip-joint General

(a) "Saint Bartholomew's Hospital Reports." Edited by A. E. Garrod, M.D., and Mr. McAdam Eccles, M.S., F.R.C.S. Vol. XXXIX. London: Smith, Elder and Co. 1904.

(b) "Wounds in War." By Surgeon-General W. F. Stevenson, C.B., A.M.S., Professor of Military Surgery, Netley, &c. Second Edition. London: Longmans, Green and Co. Price 15s. 1904.

Stevenson very properly insists upon the importance of accurate diagnosis at the earliest possible moment. This is in accordance with the teaching of modern scientific surgery, and is happily now brought within reach of the army surgeon by means of his Röntgen-ray equipment. The value of the present edition is considerably enhanced by a clear description of localisation by Mackenzie Davidson, undoubtedly the greatest living authority upon that subject. It is impossible to do justice to General Stevenson's book within the limits of a short notice, but it may be cordially recommended to readers interested in surgery as a classical and valuable work.

#### DEGENERATES. (a)

MANY startling statements are met with in this pamphlet by Dr. Rentoul. A remedy he suggests for checking the spread of lunacy is, that would-be suicides should be allowed to take their own lives without interference from the law. He also holds that "at present we are engaged in the apparently pleasant pastime of manufacturing lunatics and others of this class," and asks whether many of our philanthropic and other charitable societies do not work indirectly for the survival of the unfit. He also points out how Nature would reduce the number of lunatics to the smallest proportions were she not persistently and deliberately thwarted, and appears to deplore that we do all in our power to prevent suicide, by building palatial residences and appointing immense staffs to protect lunatics from their mental impulses. He thinks it fortunate that although thousands of pounds are expended yearly upon the care of lunatics, Nature's method—that of suicide—goes on and not only so, but increases. Nature, he states, will not forgive us for endeavouring to prevent lunatics and other degenerates from committing suicide.

"In the eight years, 1895-1903, 8,933 lunatics were discharged as recovered from the asylums under the London County Council, but of this number 2,285 were re-admitted within one year," and he asks, "Is it right and just to others that so large a proportion of recovered persons should be permitted to return to ordinary life there to beget a tainted offspring?" and we heartily agree with Dr. Rentoul that this is a most serious problem, because they cannot be kept in asylums after they become sane, and females are often discharged from an asylum recovered, to return within twelve months suffering from insanity of pregnancy or the puerperium.

The treatment he suggests is the sterilisation of mental and physical degenerates, and doubtless by some such treatment much could be done to decrease mental and physical degeneracy, although, even in this our day, we fear this line of treatment will be received by many with much disfavour.

Apart from the startling statements already quoted, there is much in this pamphlet which makes it worthy the perusal of medical men.

### Medical News.

#### Central Midwives' Board.—The Number of Examinations.

At an adjourned meeting of the Central Midwives Board, held at the offices on the 14th inst., the consideration of the examination scheme drafted by Dr. Cullingworth was continued. The question of the number of examinations to be held in a year was then raised, and its reconsideration was moved by Dr. Cullingworth, seconded by Miss Paget, and carried. Dr. Sinclair moved a resolution that the examinations should not take place more often than twice a year; he objected to the policy of "providing facilities for failures" to come up again, but no second was forthcoming. Dr. Cullingworth said that since the last meeting he had received representations from institutions engaged in the training of midwives showing if examinations were held only twice a year very great inconvenience would be felt by the schools, involving

difficulties in management which would militate against the efficiency of the training. He considered the reasons given so conclusive that he had altered his opinion. After some further discussion, in the course of which Dr. Champneys expressed the opinion that the training would be better if pupils were turned out more frequently in small batches, Dr. Sinclair begged the Board to think of "highly-trained nurses," not of "charwomen." A resolution in favour of examinations being held four times a year simultaneously in London and the provincial centres was moved by Dr. Cullingworth, seconded by Miss Paget, and carried, Dr. Champneys and Miss Oldham also voting for it. The final consideration of the scheme was deferred until October. The following institutions for the training of midwives under section C of the rules were approved: The Belfast Union Workhouse, the County and City of Cork Lying-in Hospital. Miss Paget gave notice of a resolution she wished to bring up at the next meeting, that midwives should be required to renew their licence annually. Mr. Ward Cousins asked leave to postpone a motion limiting appointment as inspectors under the Board to members of the medical profession.

#### Westminster Hospital Medical School.

THE annual distribution of prizes to the students of this school took place on the 15th inst. Colonel Sir Frederic Cardew, K.C.M.G., late Governor of Sierra Leone, who presided, after presenting the prizes spoke to the students of some of the problems that they might help to solve in their future career, especially that regarding the physical health of the people and its bearing on the manning of the army and navy. The teaching and experience of the medical profession must, he said, be one of the greatest determining factors in its solution. In the course of his address, Sir Frederic also touched on the great opening for medical men in the development of the various parts of the Empire, especially in the Tropics. The Army Medical Corps, however, now offered an attractive career to the medical practitioner and had the advantage of a pension during old age. Dr. Allchin, senior physician to the hospital, having proposed a vote of thanks to Sir Frederic Cardew, which was carried by acclamation, prizes were presented to the following gentlemen:—G. R. Ward, scholarship of 110 guineas and Treasurer's prize; H. Austin Smith, scholarship of £60; A. Davies, scholarship of £60; R. Brown, scholarship of £40 and prizes for medicine and surgery; C. F. Dawson-Smith, scholarship of £30; H. Hingston, scholarship of £60; R. Asplen, scholarship of £40; G. F. Carr, prizes for practical chemistry, physics and biology; E. G. Foote, prize for practical chemistry; L. White, midwifery prize; J. J. W. Evans, histology prize; C. Fletcher, pharmacology prize; R. S. Dollard, the Sturges prize for clinical medicine and the forensic medicine prize; and G. G. James, prizes for anatomy and physiology.

#### London School of Tropical Medicine.

Of the thirty-nine students who attended the above school during the Session, May to July, 1904, the following (all of the Colonial service), have passed the examination at the end of the course with distinction: J. Currie, A. King, E. Maples, P. N. Gerrard, C. A. Suvoong.

#### The Barker Anatomical Prize.

THIS prize of thirty guineas, offered annually and open to all students in any medical school in the United Kingdom, has just been awarded to Mr. Charles Cooper, a student of the Royal College of Surgeons, Ireland. This is the fifth year in succession that this open prize has been conferred on students of the Dublin College.

#### Trinity College, Dublin.

At the examinations during Trinity Term, 1904, Mr. John S. Joly won the Surgical Travelling Prize, and Mr. James G. Wallis the FitzPatrick Scholarship. The following gained medical scholarships:—In anatomy and institutes of medicine: Thomas O. Graham (Trinity College) and Francis O'B. Ellison (Stewart). In physics, chemistry, botany, and zoology, the following: Allman J. Powell (Trinity College) and George F. Graham (Stewart).

(a) "The Proposed Sterilisation of Certain Mental and Physical Degenerates." By Robert Reid Rentoul, M.D. The Walter Scott Publishing Co., Limited.

The Purser Medal was awarded to Mr. Francis R. Coppinger.

**Royal College of Physicians and Surgeons.**

THE following candidates have passed the Second Professional Examination:—

With Honours.—D. Adams, V. Clifford, J. D'Alton, P. G. M. Elvery, J. B. Hanafin, P. M. Keane, C. Sheahan, T. Sheehy, G. F. Shepherd.

Passed in all Subjects.—P. Blake, H. C. Carden, W. Carroll, N. E. Cussen, D. J. Hanafin, F. M. Hewson, E. Montgomery, J. B. M'Glancy, D. O'Sullivan.

Completed Examination.—R. J. Bonis, L. L. Davys, M. R. J. Hayes, J. Humphreys, W. St. L. Moorhead, F. J. Morris, D. T. O'Flynn.

**University of Aberdeen.**

At the graduation ceremony on Wednesday last, the following degrees were conferred:—

*Degree of M.D.*—Middleton Connon, M.B., C.M., James Cran, M.B., C.M., Ernest King Gawn, M.B., C.M., Henry Gibbons, M.B., C.M., Peter Harper, M.A., M.B., C.M., †David Albert Hutcheson, M.B., Ch.B., \*Arthur Hugh Lister, B.A., M.B., C.M., \*Hugh MacLean, M.B., Ch.B., John Smith Purdy, M.B., C.M., †Arthur Westerman, M.B., Ch.B., †George Nicol Wilson, M.B., C.M. \* "Highest Honours" for Thesis. † "Honours" for Thesis. ‡ "Commendation" for Thesis.

*Degrees of M.B. and Ch.B.*—Cyril Moore Smith, with second-class honours. (Passed Final Examination "with Distinction.") *Ordinary Degrees.*—Catherine Emslie Anderson, John Anderson, Wm. Robert Catto, William G. Gunn, Alexander A. Hendry, Thomas Christie Innes, Henry Williams Jeans, John Jenkins, M.A., Frederick Leonard Keith, Helen M'Glashan, Roderick Mackay, M.A., James Reid, M.A., Michael B. H. Ritchie, Fife Slater, James Hutcheon Thomson, Robert J. B. Wright.

The John Murray Medal and Scholarship was awarded to James Clark, M.B., Ch.B., and the Alexander Anderson Scholarship to Bertie R. G. Russell, M.B., Ch.B.

*Diploma in Public Health.*—Hugh Johnston, M.B., Ch.B., William Mackie, M.A., M.B., C.M.

**University of Glasgow.**

THE following have passed the fourth (final) professional examination:—

(A.)—For M.B., C.M.—Stewart Dunbar, Ernest Milton Watkins.

(B.)—For M.B., Ch.B.—Bethia Shanks Alexander, Archibald Craig Amy, Henry Græme Anderson, James Richard Sunner Anderson, Robert Daniels Bell, M.A.; David Blackley, Forrest Brechin, Charles Brown, George Yuille Caldwell, Roberta Campbell, Thomas Murdoch Campbell, M.A.; Peter Carrick, M.A.; Robert Buchanan Carslaw, M.A.; James Alexander Cowie, B.A. B.Sc.; Thomas Thornton Macklin Dishington, Charles Milligan Drew, M.A.; Hugh Harvey Fulton, John Graham, B.Sc.; George Munna Gray, John Cochrane Henderson, James Rutherford Kerr, John Kerr, Ethel MacLeod Lochhead, Peter Lowe, M.A., B.Sc.; Thomas Symington Macanlay, John Duncan M'Callum, M.A.; Donald Carmichael M'Cormick, Neil M'Dougall, James Boston M'Ewan, Tom Duncan M'Ewan, Duncan Macfayden, John M'Farlane, Alexander Stuart Murray Macgregor, James M'Houl, Ronald Mackinnon, Andrew Brown M'Pherson, James Roy M'Vail, James Marshall, Andrew Meek, Margaret Walker Millar, David Robertson Mitchell, John Muir, John Murdoch, Alexander Harper Napier, George Clement Nielson, Thomas Orr, Charlotte Reid Park, Howard Henderson Patrick, Jon Clegg Pickup, Andrew McLean Pollock, James Porter, William Murdoch Rae, William Rankin, M.A.; Donald Ronald Reid, Berkeley Hope Robertson, M.A., B.Sc.; Lawrence Drew Shaw, George Golde Smith, B.Sc., Jessie Marie Stewart, William Craig Stewart, Murray Ross Taylor, William Templeton, James White Thomson, William Young Turner, M.A.; Hugh Fleming Warwick; Robert M'Nair Wilson, Annie May Yates, Hugh Young.

The following candidates passed with distinction in the subjects indicated:—

In (a) Surgery and Clinical surgery, (b) Practice of Medicine and Clinical Medicine.—Thomas Orr. In (a) Practice of Medicine and Clinical Medicine, (b) Midwifery—Robert Buchanan Carslaw, M.A. In Surgery and Clinical Surgery—Margaret Hardy, Arthur Innes, Ethel MacLeod Lochhead, John Duncan M'Callum, M.A. George Goldie Smith, B.Sc.; Robert M'Nair Wilson. In Practice of Medicine and Clinical Medicine—Robert Daniels Bell, M.A.; David Blackley, Hugh Harvey Fulton, Tom Duncan M'Ewan, John Murdoch, Andrew Maclean Pollock, William Rankin, M.A.; Donald Ronald Reid, William Templeton, William Young Turner, M.A. In Midwifery—Forrest Brechin, Peter Carrick, M.A.; Louis Leisler Greig, Margaret Walker Millar, David Robertson Mitchell, Howard Henderson Patrick, David Penman, William Craig Stewart, John Unsworth.

**Conjoint Examination Board in Ireland.**

THE following candidates have passed the first Professional Examination by the Royal College of Physicians and the Royal College of Surgeons:—

(a) *Honours*—T. C. Boyd, T. P. Cormack, J. C. L. Day, C. Hyland, G. Patton, W.G. Ridgway, A. Sheridan, H. W. White.

(b) *In all subjects.*—G. E. Beggs, G. Collins, J. J. Cuskelly, G. A. Finegan, J. A. J. Flannery, M. J. Hawkshaw, F. N. Holden, D. J. Hurley, H. W. Kay, W. J. P. Lillis, D. J. Lyne, T. J. Lyons, J. McHugh, J. T. McKee, P. Maguire, J. P. Morgan, T. N. Neale, E. Ryan, M. J. Saunders, H. B. Sherlock, J. M. Smyth, C. H. Stringer, W. C. Townsend.

(c) *Completed Examination.*—S. W. Hudson, T. J. McDonnell.

**Royal College of Physicians and Surgeons and Faculty of Physicians and Surgeons, Glasgow.**

At the quarterly examination of the Conjoint Board, held in Edinburgh, and concluded on July 22nd, the following candidates passed the Final Examination and were admitted L.R.C.P.E., L.R.C.S.E., and L.F.P. & S.E.:—Charles Henry Thomas, Canada; William Herbert Boalth, Kampti, India; Broderick Edward Middleton Newland, Bangalore; Bernard Beaumont Westlake, Chippenham; Eyre Vincen; Smith, Kingston, Jamaica; Bertram Ingram, Victoria; James Watson, Edinburgh; Arthur George Thompson, Ontario; Franklin Christian Richards, South Dakota; Frederick Etherington, Ontario; Edward Rainsford Mumford, Norwich; Charles Richard Whittaker, Lancashire; Charles Grange McGreer, Ontario; Annjuta Kellgren Cyriax, London; Daniel Michael Donovan, Cork; James Grieve Cormack, Anstruther; William Boyd, Co. Derry; Lambert Kenneth Rodriguez, Travancore; Eileen Josephine FitzGerald, Melbourne; Henry Gordon Campbell, Dundee; Dwarkanath Dharmaji Kamat, Bombay; Alexander Douglas Fox, Brighton; Ramchandra Kashinath Dhuru, Bombay, Nigel Oliphant, St. Andrews; David Arnold Hastings, Ireland; Vasantio Dinanath Madgavkar, Bombay; Narindra Singh Sedhi, Punjab; Sorabji Jamasji Bhatena, Bombay; William Vincent Saint John Sutton, Cork; and Joseph Simon de Souza, Bombay; and five passed in Medicine and Therapeutics, nine in Midwifery, and five in Medical Jurisprudence. Fifteen other candidates passed the First Examination, eighteen passed the second Examination, and sixteen passed the Third Examination at the recent meetings of the Board.

**Society of Apothecaries of London, July, 1904.**

THE following candidates having passing the necessary examinations, have received the L.S.A. diploma of the Society, entitling them to practise medicine, surgery, and midwifery:—L. F. Cope, C. Kellgren, and T. R. Waltenberg.

**Royal College of Surgeons in Ireland.**

*Fellowship Examination.*—Mr. C. W. H. Fleming, L.M. and S. Dublin University, having passed the necessary examination, has been admitted a Fellow of the College. Miss S. H. Commissariat, L.M. and S. Bombay University, has passed the primary part of the Fellowship examination.

## Notices to Correspondents, Short Letters, &c.

**CORRESPONDENTS** requiring a reply in this column are particularly requested to make use of a *distinctive Signature or Initial*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

**ORIGINAL ARTICLES** or **LETTERS** intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

**CONTRIBUTORS** are kindly requested to send their communications, if resident in England or the Colonies, to the Editor at the London office; if resident in Ireland, to the Dublin office, in order to save time in re-forwarding from office to office. When sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

**REPRINTS.**—Reprints of articles appearing in this journal can be had at a reduced rate providing authors give notice to the publisher or printer before the type has been distributed. This should be done when returning proofs.

**BOLTONIENSIS.**—Pettenkofer's theory of the relation of ground water to enteric fever has never been accepted unreservedly by British authorities upon hygiene. It is, of course, possible that different local conditions have altered the case in Munich, where Pettenkofer made his observations. In that city the soil is porous, and the high ground water may have had exceptional opportunities of working mischief from the presence of an enormous number of leaking cess-pools. The point should, of course, always be borne in mind by the scientific sanitarian whatever his field of work.

### SURGERY AND SERMONS.

"I USED to give him advice about his operations, and he used to criticise my sermons. We watched his first performance of tracheotomy with the deepest interest, and I am sure his remarks helped me with my sermons." So spoke the Bishop of London last week concerning his early friendship with a hospital house surgeon, the occasion being prize day in connection with the Medical School at St. Bartholomew's Hospital.

**DR. H. T. S.**—It would be more satisfactory to both parties if you referred the question to an expert. There can be no arbitrary standard for the valuation, the value of practices varying according to circumstances. With regard to the other points, these are "cut and dried," and afford safeguards alike to the vendor and purchaser.

**MR. HARMAN.**—Your foreign diploma does not confer the right to practise in this country: that is to say, it does not convey the status of a registered medical practitioner. It is not for us to advise you how to evade the law, nor would you be wise to attempt it.

**DR. J. W. M.**—Your interesting case is marked for early insertion. **MR. CLEMENT SERES'** letter is unavoidably held over for want of pace: but enclosed communication has been read and posted to the gentleman concerned.

**DR. WATSON.**—A similar question was asked and replied to in our last week's issue under the signature of "A Subscriber," to which we would refer you.

**DR. K.** See reply to Dr. J. W. M.

## Vacancies.

- Ayr District Asylum.**—Junior Medical Officer.—Salary £120 per annum, with board, furnished apartments, attendance, and washing. Applications to the Medical Superintendent.
- Carlisle Non-Provident Dispensary.**—Resident Medical Officer. Salary £150 per annum, with apartments (not board). Applications to the Honorary Secretary, Mr. G. A. Lightfoot, 23 Lowther Street, Carlisle.
- Stirling District Asylum, Larbert, N.B.**—Assistant Medical Officer. Salary £150 per annum, with board, &c. Applications to the Medical Superintendent.
- County Borough of South Shields.**—Medical Officer of Health. Salary £300 per annum. Applications to J. Moore Hayton, Town Clerk, Court Buildings, South Shields.
- Whitehaven and West Cumber and Infirmary.**—House Surgeon. Salary £150 per annum, with rooms and attendance. Applications to the Secretary.
- Brecon and Radnor Asylum, Talgarth, R.S.O.**—Assistant Medical Officer. Salary £140 per annum, with furnished apartments, board, attendance, and laundry. Applications immediately to the Medical Superintendent.
- Rotherham Hospital and Dispensary.**—Senior House Surgeon. Salary £110 per annum, with rooms, commons, and washing. Applications to the Secretary, C. S. Baylis, 19 Moorgate Street, Rotherham.
- Leighton Buzzard Union.**—Medical Officer. Salary £260 per annum. Applications to Chas. W. B. Calcott, Solicitor, Leighton, Buzzard.
- Shillelagh Union.**—Medical Officer. Salary £120 per annum. Applications to J. Hopkins, Workhouse, Shillelagh, Co. Wicklow.
- House Surgeon, for a small Hospital in the Midlands.** Salary £100 per annum and board. Applications to Mr. P. W. Walker, 18 Waterloo Street, Birmingham.
- Southwark Union, London.**—Second Assistant Male Medical Officer at the Infirmary East/Dulwich Grove, S.E. Salary £100 per annum, with board, lodging, and washing. Applications to Howard

C. Jones, Clerk, Union Offices, John Street West, Blackfriars Road, S.E.

## Appointments.

- COLLINS, ETHELBERT, L.R.C.P.Lond., M.B.C.S.,** Coroner for the Bishop's Stortford District of East Hertfordshire.
- MUMFERRY, PERCY LOCKHART, B.C.Cantab., F.R.C.S.Eng.,** Assistant Surgeon to the North-Eastern Hospital for Children, Hackney Road.
- NEAL, F. C., M.R.C.S., L.R.C.P.,** Clinical Assistant to the Chelsea Hospital for Women, S.W.
- OARLEY, ADAM R. H., L.R.C.P., L.R.C.S.Edin.,** Third Honorary Anaesthetist to the London Throat Hospital, Great Portland Street.
- TURNER, F. D., M.B.Lond., M.R.C.S., L.R.O.P.,** Medical Officer to the Post Office and Medical Examiner to the Board of Education at Huddersfield.

## Births.

- BULLIED**—On July 17th, at The Old Vicarage, Midsomer, Norton-Somerset, the wife of Arthur Bullied, L.R.C.P., F.S.A., of a son.
- GUTCH**—On July 23rd, at 28 Ponnereau Road, Ipswich, the wife of John Gutch, M.D., B.C.Cantab., of a daughter.
- HAVELOCK**—On July 21st, at Sunnyside, Montrose, N.B., the wife of John G. Havelock, M.D., of a son.
- MANLOVE**—On July 21st, at 78 Warrior Square, St. Leonards-on-Sea, the wife of J. E. Manlove, L.R.C.P., M.R.C.T.J., of a son.
- YOUNG**—On July 21st, at 2 Palmeira Terrace, Hove, Sussex, to Dr. and Mrs. B. J. Erskine Young, a daughter (prematurely).

## Marriages.

- PERCIVAL-WARNER**—On July 21st at St. Peter's Church, Newcastle-on-Tyne, Archibald Stanley, M.A., M.B.Camb., youngest son of the late Stanley Percival, to Winifred Helen, youngest daughter of the late William Warner.
- THOMAS-ATKINSON**—On July 20th, at St. Mary's Church, Handsworth, Yorks, George Crewdson Thomas, M.D., M.R.C.P., of Sydenham, only son of George E. Thomas, of Swainswick, Bath, to Evelline Mary, elder daughter of William Atkinson, The Birklands, Handsworth.

## Deaths.

- MANN**—On May 18th, at Kisumu, British East Africa, Harold E. Mann, M.R.O.S., L.R.O.P., D.P.H., Medical Officer East Africa Protectorate, son of the late Major General Gother F. Mann, C.B., R.E., aged 39.
- SIMON**—On July 23rd, at 40 Kensington Square, London, in the 88th year of his age, Sir John Simon, K.C.B., M.D.Dub., M.R.C.S., F.R.S., formerly, Medical Officer of H.M. Privy Council, and Consulting Surgeon to St. Thomas's Hospital, London.

## OPERATIONS.—METROPOLITAN HOSPITALS.

- WEDNESDAY.**—St. Bartholomew's (1.30 p.m.), University College (2 p.m.), Royal Free (2 p.m.), Middlesex (1.30 p.m.), Charing Cross (3 p.m.), St. Thomas's (2 p.m.), London (2 p.m.), King's College (2 p.m.), St. George's (Ophthalmic, 1 p.m.), St. Mary's (2 p.m.), National Orthopaedic (10 a.m.), St. Peter's (2 p.m.), Samaritan (9.30 a.m. and 2.30 p.m.), Gt. Ormond Street (9.30 a.m.), Gt. Northern Central (8.30 p.m.), Westminster (2 p.m.), Metropolitan (2.30 p.m.), London Throat (9.30 a.m.), Cancer (2 p.m.), Throat, Golden Square (9.30 a.m.), Guy's (1.30 p.m.).
- THURSDAY.**—St. Bartholomew's (1.30 p.m.), St. Thomas's (3.30 p.m.), University College (2 p.m.), Charing Cross (3 p.m.), St. George's (1 p.m.), London (2 p.m.), King's College (2 p.m.), Middlesex (1.30 p.m.), St. Mary's (2.30 p.m.), Soho Square (2 p.m.), North-West London (2 p.m.), Chelsea (2 p.m.), Great Northern Central (Gynaecological, 2.30 p.m.), Metropolitan (2.30 p.m.), London Throat (9.30 a.m.), St. Mark's (2 p.m.), Samaritan (9.30 a.m. and 2.30 p.m.), Throat, Golden Square (9.30 a.m.), Guy's (1.30 p.m.).

### THE TREATMENT OF CHRONIC RENAL DISEASE. (a)

By W. HALE WHITE, M.D.Lond., F.R.C.P.,  
Physician, Guy's Hospital, London, &c., &c.

DR. HALE WHITE, in opening the discussion on the above subject, said that the exigencies of time compelled him to limit it to the treatment of the disease usually known as chronic Bright's disease. Many physicians have based their treatment largely upon the albuminuria, but this is wrong, for, probably, not much harm follows the mere loss of albumen in the urine, the amount so lost is always small and could be easily compensated for by a little more in the food, and, further, in many diseases such as cystitis, large amounts of albumen are lost in the urine, but no one thinks of directing the treatment directly against the albuminuria. The value of the albumen in the urine is that it enables us to diagnose the disease, and to estimate the progress it is making. It was pointed out that very often towards the end of a case, when the patient was at his worst, the amount of the albumen in the urine was less.

Passing to the cardio-vascular symptom, two conditions are met with. Some patients have a hypertrophied heart and high tension pulse, others are suffering from a weak, feeble heart. The first group must keep down their blood pressure, for they run considerable risk of fatal hæmorrhage, physical exercise should be gentle, the bowels should be loosely opened once a day to avoid strain at stool, meals should be small, alcohol should not be taken, and very little meat or soup or meat essences on account of the extractives in them. There should be no excessive drinking of fluids, and digitalis and other drugs which raise the blood pressure should not be given. Sometimes the weak, feeble heart met with in chronic Bright's disease is brought about by the fact that the patient has been starved; under the impression that most articles of food irritate the kidneys, he has been kept on nothing but milk. It is surprising how such patients are benefited by giving them a little meat and sometimes a little alcohol helps them. Often patients with Bright's disease are not allowed enough exercise, with the result that they become fat, and this is very bad for them because the already enlarged heart is not capable of conveying

the blood properly to the extra amount of fat tissue, hence the organ dilates.

Unless the heart has dilated, severe œdema is not a common symptom of chronic Bright's disease, although it is frequently met with in chronic tubal nephritis. It is best treated by posture. If it is in the legs they should be raised; if in the lungs, the patient should be turned from side to side. Diaphoretics do not often help much, but on the other hand the œdema subsides best when but little fluid is drunk. Still, the most efficient way to get rid of œdema is to puncture the legs with needles. The amount of fluid that will drain off is very great, and this relieves the œdema of other parts. Great care must be taken to see that the punctures in the legs are kept sweet, for the tissues of patients with Bright's disease are particularly liable to septic inflammation.

Many methods of treatment have been directed to avoiding substances which are supposed to be harmful because they irritate the kidneys. Certain drugs undoubtedly do this; for example, carbolic acid, cantharides, and turpentine. Other drugs are excreted with difficulty, such as mercury, lead, and digitalis. There is much difference of opinion about morphine. It certainly often benefits the convulsions of uræmia, but, inasmuch as the subjects of chronic Bright's disease are very easily poisoned by it, it should be very rarely used. We know really very little as to whether any articles of diet irritate the kidneys. Excessive drinking of alcohol is bad, but only 3 per cent. to 5 per cent. of alcohol, when only a moderate quantity is taken, is excreted by the kidneys. Therefore, a little alcohol does not irritate the kidneys at all. The guide in giving alcohol in Bright's disease is the pulse; if the tension is high it must not be given, if the tension is low it is often beneficial. As we are very ignorant as to the kind of food which irritates the kidneys, probably most patients with chronic Bright's disease are best if they take ordinary plain simple food in such quantity that their weight keeps about normal. There is no evidence that one form of meat is better than another, or that chicken and fish are better than beef and mutton, and most of the statements with regard to the dieting of patients with chronic Bright's disease are based upon entirely insufficient evidence. Often the patients are over-dieted, their food is unduly restricted, and they feel very much better when they are allowed more latitude. This is especially true of chronic tubal nephritis. Tea, coffee, and tobacco should all be used with great moderation by sufferers from chronic nephritis,

(a) Abstract of Paper read at the Oxford Meeting of the British Medical Association, July, 1904.

as we have already seen how important it is to keep the blood tension normal, and any of these three will render the pulse irregular, rapid, and of low tension. As a rule, too, much water drinking is bad, for if much is taken œdema will not subside, and excessive water drinking increases nitrogenous metabolism, and also a large amount of water raises the blood pressure.

There can be little doubt that uræmia is a form of poisoning. What the poison is we do not know. There is no evidence that it is derived from the food, for the onset of uræmia has not been shown to be associated with any particular article of diet, and large amounts of food in healthy persons do not lead to uræmia. Dr. Hale White quoted a case which was observed by himself and Dr. Spriggs, in which 5,000 kilocalories of food were taken a day for fifty-five days, at least 120 grammes of nitrogen were retained, but the patient had not uræmia. Further, there is no diminution in the output of nitrogen during uræmia. As there is no evidence that uræmia is connected with the food, it is supposed that the poison is produced within the body. As we know of no antidote to it nor of any way of stopping its formation, all we can do is to render the excretory channels of the body active. Therefore, the bowels should be kept open, the patient should be made to sweat, and any diarrhœa and vomiting should not be checked. Often benefit follows transfusion, probably because some of the poison is washed out; bleeding, too, is often beneficial. As this treatment is correct for uræmia, it is well for a patient with chronic Bright's disease always to keep the bowels well open, and to have a hot bath occasionally so as if possible to ward off uræmia. Inasmuch as in Egypt the heat is great and the humidity of the air is low, it is an ideal climate for sufferers from chronic Bright's disease, for they perspire quickly and the perspiration rapidly evaporates.

Dr. Hale White concluded by saying that he had confined himself strictly to points in the treatment of which he had had personal experience, and he left it for other speakers to give their views upon the treatments to which he had not alluded.

### OUR SANITARY NEEDS, WITH SPECIAL REFERENCE TO THE NATIONAL HEALTH. (a)

By SIR W. SELBY CHURCH, K.C.B., M.D.,  
Physician, St. Bartholomew's Hospital.

AFTER a brief reference to the condition of medical knowledge in 1868, when the Association last met in Oxford, it was pointed out that the meeting could almost be taken as marking the commencement of our present views concerning febrile and some other diseases, Lord Lister having the year before read at Dublin his paper on "The Antiseptic Principle in the Practice of Surgery," and the medical world just beginning to recognise the infectivity of tubercle. Allusion was made to Sir Wm. Gull's address in 1868 on "Medicine," and our present knowledge contrasted with his statement about infectious diseases, that they spread by emanations from the sick, but whether as amorphous material or as germs we know no more than a thousand years ago. The importance of our acquaintance with

the internal secretions of organs was touched upon, and disappointment expressed that expectations roused by the success of thyroid feeding in myxœdema had not as yet been fulfilled in the case of diseases of other organs.

After a short reference to the condition of medical practitioners in Greece and Rome, and the evolution of the profession in this country during mediæval times, the rise of sanitary legislation was considered, and the passing of the Medical Act of 1858 was taken as marking the advent of a new branch of medicine—Preventive or State Medicine. The need for codification and simplification in our sanitary procedure was pointed out, and the necessity for the Medical Department of the Local Government Board having more power and acting as an advisory as well as a supervising body. The need for a much closer supervision of the manufacture and sale of food-stuffs was considered, and the desirability of health authorities having greater powers than they at present possess in preventing the overcrowding of localities as well as houses.

The mistake of rural communities municipally adopting the principles of liquid sewage disposal, notwithstanding the difficulties that are known, was referred to, and the disadvantages attendant on the overgrown size of buildings in our towns was alluded to. The Registrar-General's returns were quoted as showing that the mortality increased with the denseness of the population, and that this was especially the case with infant mortality. In conclusion, the Association was urged to use its influence to spread the knowledge of sanitation, and to point out both to the public and the Government the desirability for a physical census of the nation being taken from time to time, and the necessity for the registration of the physical condition of the children in our primary and secondary schools being kept.

### THE SEASIDE CURE: ITS INDICATIONS AND CONTRA-INDICATIONS.

By ALFRED S. GUBB, M.D. (Paris). &c.,  
Of *Mustapha Supérieur*, Algiers, and *Aix-les-Bains*.

THE season for sea-bathing has returned, and practitioners in general will be asked to express an opinion on the advisability of going to the seaside for the restoration of health. It is by no means easy to formulate an opinion on the subject based on scientific principles, because the "sea-air cure" has not been methodically investigated. It has been empirically employed from time immemorial, but in truth more on the personal initiative of the patient than on the advice of physicians who have taken the trouble to think the matter out, and who can specify its indications and contra-indications. At the Thalasso-therapeutic Congress, held at Nice last year, a number of papers were read on the subject, some of them of considerable value since they were based on numerous observations which throw fresh light on an obscure subject.

We have first to ask ourselves, What is the action of the "sea-cure"? This comprises two divisions, viz., the action of sea-air, *i.e.*, the purely climatic aspect, and, secondly, the action of sea-baths. Now the properties of sea-air may be summarised as follows: The air at sea level attains its maximum density, and the barometric pressure is at its highest. Under these conditions the respiratory movements are reduced in number but increased in amplitude. It follows that the air circulates more freely in the respiratory tract, and that the circulation of blood in the lungs takes place more easily. Moreover, a given volume of sea-air contains a larger proportion of oxygen than inland or mountain air, and this determines an increase in the

(a) Abstract of the Address on Medicine given at Oxford, July 28th, 1904.

number of red corpuscles as well as an augmentation in the proportion of hæmoglobin. Then, too, sea-air is markedly freer from dust and consequently from ærial micro-organisms than land air, advantages upon which it is hardly necessary to insist. The prevailing temperature is more uniform, but, on the other hand, the winds are more frequent and stronger. Among their effects must be noted that they promote evaporation from the cutaneous surface and cause a loss of surface heat which stimulates organic exchange.

Light, which is such an important factor in a climate, is at its maximum at the sea-shore, and, light for light, it is richer in chemical and therapeutically active rays. It exerts a pronounced stimulating action on metabolism and produces a beneficial action on the vasomotor system, which Huchard describes as "the peripheral heart which, ramifying beneath the skin, regulates and governs the function of the central heart."

It is generally admitted that sea-air contains a larger proportion of ozone, and, along with this, a larger proportion of aqueous vapour. In districts immediately adjacent to the seaboard the air, especially in rough weather, becomes laden with fine spray, containing the alkaline chlorides, bromides, and iodides, though, according to Lalesque, the proportions of these salts present in sea-air has been much exaggerated. Gautier and Duphil, as a matter of fact, only found 22 and 15 thousandths of a milligramme per litre of sea-air.

It will be seen, then, that sea-air is made up of elements which, for the most part, are stimulants. It stimulates metabolism, at any rate in the sick, and for a limited period—until they have become acclimatised—in the healthy. Clinically it increases the appetite, and indirectly brings about an increase of body weight. The circulatory and respiratory functions are slowed, cutaneous perspiration and diuresis increase, the muscular strength is enhanced, and the proportion of red corpuscles in the blood is raised.

#### SEA-BATHING.

The action of sea-baths is markedly stimulating. They influence the respiratory and general exchanges, first of all by chilling the cutaneous surface, as in any application of cold hydrotherapeutics, and these effects are enhanced by the richness of the water in mineral constituents; lastly, the movements of the bather in swimming and the mobility of the water itself constitute a genuine massage of the whole body.

Albert Robin and Binet explain the action of sea-baths as follows: "The various elements of activity in a sea-bath stimulate the peripheral nerve terminals, and the extensive nervous surface of the integument, and this stimulus is transmitted centripetally to the nerve centres, which preside over general nutrition."

The action of the "sea-treatment" cannot be better summarised than in the words employed by Dr. Robin, in his address at the Congress just referred to: "Denser, of a more uniform temperature, rendered more salutary by the winds and the waves, saturated with salt iodised vapours, bathed in light, it stimulates all the vital functions—the appetite, digestion, assimilation, and the various chemical acts of elementary nutrition. Respiration finds therein purer and more stimulating elements, it regulates hæmatosis, and molecular regeneration." Sea-baths, moreover, accentuate the double process of assimilation and disassimilation which together constitute nutrition, this prime manifestation of vital energy. It promotes the combustion of the residues of organic activity which, instead of stagnating in the organism and by their retention engendering functional disturbances which are the forerunners of actual disease, are rendered soluble and their elimination from the economy thus facilitated. Sea-air and sea-bathing, these powerful modifying agents of intra-organic exchanges, are, therefore, a means of regeneration, of "reincorporation," as it was called by the ancients, who thought, reasonably enough, that by renovating the tissues they could modify inherited and acquired tendencies and wash away, so to speak, latent morbid predispositions inherent to particular organisms.

#### INDICATIONS AND CONTRA-INDICATIONS.

The reply to the question as to the special diseases

likely to derive benefit from the "sea-cure" is to be inferred from what we have just said, *i.e.*, all diseases characterised by a slowing down of nutrition. Whenever in a given patient we wish to accelerate general and respiratory exchanges, we should send him to the sea-side. Formulated in this general way the conclusion appears simple enough; but in practice the point is often difficult to decide and requires for its proper appreciation precise observation and numerous distinctions. Let us begin by asking ourselves what are exactly the modifications of nutrition, provided by sea stimulation. According to Robin and Binet the organic exchanges are accelerated *en bloc*, and the increased activity bears more particularly on nitrogenous metabolism. The excretion of mineral elements is reduced, the evolution of ternary substances is more satisfactory, the proportion of uric acid diminishes, the assimilation of alimentary phosphates is more perfect, the increase in the proportion of earthy phosphates to the phosphoric acid testifies to more active changes in the osseous and nervous systems; the solubility of the fluids for uric acid is enhanced, the assimilation of nitrogenous substances is markedly increased, and depends not upon greater organic combustion, but upon a better assimilation of these principles.

How, then are we to establish the nutritive budget of the patient? To do so not only takes time but requires a special laboratory and a chemical expert. Robin, however, holds that it is sufficient to weigh the patient regularly. The amount of albumen consumed per kilogram of body weight in the twenty-four hours is estimated by noting the elimination of chloride of sodium. If the consumption of albumen, thus measured, increases or even remains stationary, while at the same time the excretion of chloride of sodium diminishes, the patient should not remain at the sea-side. A further consideration has to be borne in mind that of the particular station to which the patient is to be sent. The seaside climate is not the same everywhere. We have discussed its fundamental qualities, but a host of factors associated with the topography of the place, its exposure to winds, its relative humidity, its vegetation, &c., modify its curative action. In a particular resort, well protected from north and west winds, near which there are pine forests, we shall obtain sedative effects, whereas in another resort, which is swept by the winds and is poor in vegetation, the effects will be purely stimulating. The neighbourhood of Algiers, for instance, shut in as it is by mountains; will always present a much higher hygrometric record than stations higher up the hills, which are better ventilated and retain less cloud and damp. Certain resorts may be divided into zones according to the distance from the sea-shore of its various districts, their exposure to wind, their aspect in regard to the sun, and their flora. The slopes of Mustapha Supérieur, above Algiers, will prove beneficial to many categories of patients who would derive anything but benefit from a sojourn to the west of Algiers at St. Eugene, for example.

In addition to the peculiarities of the particular station we must also study the peculiarities of the patient. The inadequacy of the nutritive processes may not be due to any slowing down thereof, but to excessive demands thereon. In such cases the seaside is unsuitable, for it would accentuate the overstrain. The stimulating effects of sea-air on the other hand, are not produced in every instance. Seaside practitioners meet with patients in whom metabolism is exaggerated, who nevertheless bear seaside residence very well and even improve. The stimulant effects are also modified by acclimatisation. Lastly, the different zones of a particular station may, as we have shown, possess different curative qualities if the treatment be modified accordingly.

Under these circumstances the seaside treatment may be advised in respect of the following categories of patients—anæmic patients with slowed nutrition, convalescents from febrile diseases, sufferers from malaria, patients of lymphatic temperament, the

strumous and in certain forms of neurasthenia with imperfect nutrition. The treatment is also suitable for rickety subjects, and in many osseous affections. Cases of chronic tuberculous adenitis with low nutrition will often be benefited by residence at the seaside.

The victims of pulmonary tuberculosis in whom the nutritive exchanges are usually over-active, are better at a distance from the sea, but there are exceptions to this rule, for in Algiers we are familiar with instances in which great and permanent benefit has followed residence near the sea in such cases. This question has given rise to much discussion, and although, as a general rule, we may admit with Robin that our object must be "to calm the tuberculous, to extinguish the fire that is consuming them and not blow it into a flame by the sea breeze," that does not prove that these patients will derive no benefit from the seaside. We have shown, indeed, that the topography of certain stations attenuates the stimulating effects.

According to Manquat the tuberculous may be classified in four categories—(a) torpid tuberculosis in persons whose nutritive exchanges are normal or sub-normal, whose circulation is calm, whose lesions are circumscribed and stationary; these may improve at the seaside; (b) those whose lesions evolve *per saltum*, i.e., acute outbreaks followed by periods of remission of variable duration. These should be sent to a sedative station and residence too near the sea must be prohibited; (c) cases of acute, rapidly-progressing tuberculosis should never be allowed near the sea; (d) the incurable cases, in which the choice of a climate is of less importance and may be left in great measure to individual taste.

Persons predisposed to pulmonary tuberculosis, whose nutritive changes are unduly active, should be kept at a distance from the sea. According to Robin, the great majority of the tuberculous derive no benefit from the seaside. The only exceptions to this rule are (1) the tuberculous whose respiratory exchanges are not in excess, i.e., about 8 per cent. of such cases; (2) the phthisical who, although their respiratory exchanges are in excess, eat, digest, and assimilate badly in such wise that the excess of oxygen which they consume hastens the consumption of their own tissues. In these a temporary stimulation of the digestive and assimilative functions will divert to the ingested food a portion of the surplus oxygen. The Mediterranean seaboard may, according to Huchard, be recommended to cardiac patients in winter on condition that they have not reached the period of asystole. The seaside, on the other hand, is contra-indicated in aneurysm and dilatation of the aorta, in coronary angina pectoris, in pseudo-angina pectoris of neuralgic origin, and in cardiac states associated with the phenomena of hyper-systole, or cardiac excitement with frequent attacks of palpitation.

Rheumatic subjects with acute or subacute attacks usually find their state to be aggravated by residence close to the sea, and the same may be said of arthritics subject to neuralgic attacks. Neuralgics and the so-called "herpetics," are oftener than not, worse near the sea, and moist climates in general are injurious to them.

Arthritics, whose nutrition is merely slowed; the subjects of arterio-sclerosis without grave complications; the obese by nutritional slowing down; and the gouty and hyposthenic dyspeptic, may derive marked benefit from the seaside. Certain phosphaturic neurasthenics also benefit therefrom, but the pure neurasthenic will, as a rule, do better in a sedative climate.

Lastly, hysterical subjects are often worse near the sea, or feel so, but they need not on that account be sent elsewhere. According to Mendelsohn these patients often complain of stimulating phenomena in no wise due to any modification of the special excitability of the sensory and motor nervous system. Their state is due rather to a psychical condition brought about by emotional hyper-sensitiveness. Should this psychical state not rapidly yield to acclimatisation or

"suggestion," it is preferable not to insist, but to advise removal from the neighbourhood of the sea.

#### INDICATIONS AND CONTRA-INDICATIONS OF SEABATHS.

Sea-baths are suitable for the rickety, the lymphatic, the strumous, the subjects of osseous and glandular tuberculosis, in anæmia with slowed nutrition, in obesity by defective metabolism, in those predisposed to gout, in chronic auto-intoxication, in hyposthenic dyspepsia, in convalescence after febrile diseases, and for diabetics when nutrition has begun to give way.

### THE PRINCIPLES OF OPEN-AIR TREATMENT OF TUBERCULOSIS.

By T. CARSON FISHER, M.D., &c.,  
Dunstone Park Sanatorium, Paignton, Devon.

In recent years much interest has been shown by the profession and the public in the "open-air" treatment of tuberculosis. It has been discussed in medical and lay papers, in crowded congresses, and it has now quite a literature of its own. In spite of this publicity there are vague and conflicting opinions regarding the scope, limitations, and results of "open-air" methods.

The writer having for many years treated consumption in various climates, both at home and abroad, having been for some years past Resident Physician in various home sanatoria, and having visited many others, endeavours in this article to give a brief summary of various practical points in open-air, hygienic, or sanatorium treatment of tuberculosis.

The former pessimism about consumption has passed away, and in its place there is risk of somewhat undue optimism. It is certain that, according to pathological and clinical research, the disease is spontaneously curable in a considerable percentage of cases.

Dr. Bulstrode, (a) in his Milroy Lectures, quotes an extract from one of Professor C. Allbutt's addresses: "I am guilty of no extravagance when I suggest that one-third of you who hear me, wittingly or unwittingly, are, or have been, affected with tubercle."

The human organism is refractory to the tubercle bacillus. Some are practically immune. Authors such as Flugge state that the cough spray-drop of the phthisical contains tubercle bacilli; yet doctors, students, nurses, and others inhale these daily with apparent immunity.

The power of resistance in most people is greater than was imagined, or the virulence of the toxins has altered as in other infective diseases. Opinion is unanimous that "open-air" or hygienic treatment is the most potent weapon against the attacks of the tubercle bacillus, except in advanced cases.

To aid the natural immunity, to improve the power of resistance, and promote the process of repair are the objects of this treatment, and this can be best attained in a suitable sanatorium.

The evolution of this treatment during the last half-century is well known. It was foreshadowed in England by Bodington and others fifty years ago, but in Germany it was developed and systematised, and the measures for the control of the disease are now more complete there than in any other country. (b)

In British sanatoria, German methods have been modified in various ways. Without detracting from the merits of the foreign system, experience shows that some details can with advantage be altered or omitted as unsuited to English character and habits. The general principles and routine of treatment in most British sanatoria are similar, however they may differ in details. The main factors may be summed up as follows:—

1. Pure air always.
2. Abundant sunlight.
3. Regulated rest.

(a) *Lancet*, August 8th, 1903.

(b) Bulstrode, *Lancet*, August 8th, 1903.

4. Graduated exercise.
5. Abundant nourishing food.
6. Careful medical supervision.

1. *Pure Air*.—The history of Arctic exploration shows that in those frigid regions there is remarkable immunity from rheumatic affections, catarrhs, and common colds. The doctor to the Italian expedition (a) which reached the furthest North comments on this significant fact, and attributes it to the purity of the air and the absence of micro-organisms, the cold and the continuous and intense light being antagonistic to their development. Other Arctic explorers record similar facts.

The microbes to which are due catarrhs, influenza, common colds, and such like infest ordinary houses, but do not exist where the air is kept pure. In open-air sanatoria such ailments are unknown, unless they are imported, and even then they are short-lived.

The first aim of the treatment is to substitute pure air constantly for the unclean and vitiated atmosphere in which most phthisical patients try to live for months or years. An "open-air" life is the first essential of hygienic treatment.

In fine weather the patient can spend the day out of doors with adequate shelter from wind or hot sun. On wet or stormy days he can rest in a suitable shelter or verandah. In most sanatoria huts are erected in different positions, those for winter facing south, and others for summer facing north. Revolving shelters are very useful. Balconies with proper protection from wind, rain, or glare are suitable for weaker patients. At night the head of the bed must be close to the open window. Shelter from strong winds or rain can be secured by moving the bed about, or by some screen arrangement. The larger the window space the better, since the air of the room is more easily kept pure, and there are fewer spaces for stagnant air. It has been found that febrile patients do better in a chalet with windows on all sides than in an ordinary bedroom with open windows. The furniture must be scanty; carpets, curtains, wall-papers, and everything that can harbour dust should be abolished. Hence the walls should be smooth, varnished, or dis-tempere; the utmost cleanliness is essential, and proper precautions taken regarding sputum and disinfection.

The constant purity of the air causes night sweats to disappear; sleep comes readily; cough and fever lessen; increased appetite comes, and at the end of the first week there is usually a gain of some pounds in weight. Every patient should have a separate bedroom to prevent disturbance by talking, coughing, &c., and to ensure privacy and rest. Of course, in public sanatoria this is sometimes difficult, though various simple kinds of hut can be erected cheaply; but in private sanatoria it is the rule. Personal experience of a wooden chalet in an English winter convinces the writer that it is then fit only for stronger patients with a good circulation. Delicate consumptives require more comfort and warmth than can be attained in a fragile wooden structure. At other seasons of the year it has its advantages. The site should be specially chosen to give pure air, with shelter from strong or cold winds. Hence it should be in the country, away from dust, smoke, fog, or noise; isolated, and in its own grounds. It is quite out of place in or near a town.

An elevation of some hundreds of feet above sea-level gives bracing and invigorating air as well as more ozone. Anyone who has lived in a low-lying place and migrated to the uplands must readily admit his improved health, energy, and sense of well-being.

The elevation must not be too great on account of severe cold and gales in winter. Visitors to British sanatoria will find them in varied positions, and doubtless some cases do best in low, sheltered places.

It is possible that the situation may be too shut in by hills, trees, hedges, &c., so as to prevent free circulation of air, especially in summer. Nearness to the sea is not an advantage. Practical men generally

advocate a site elevated and airy, but not too exposed or wind-swept.

The experts who advised regarding the King's Sanatorium recommended a high situation on the slope of a hill facing south, with adequate shelter from prevailing winds. An ideal position is hard to find, free from every drawback, and in the country the question of supplies has to be considered. The nature of the soil is important. It should be of a porous nature, readily drying after rain. Damp, heavy clay soils should be avoided.

2. *Abundant Sunlight*.—A high situation gets more sunlight than a low one, where morning and evening mists are liable to prevail for several months in the year. A number of places in the British Isles get a fair amount of sunshine even in winter.

In the *Lancet* (April 16th, 1904, p. 1071), comparison is made between the winter temperature chiefly of the South of England and the Italian and Rivieran resorts, not all to the advantage of the latter; while as regards diurnal range of temperature and freedom from frost, the English places are superior. The aggregate rainfall of these home stations was lower, though there were more wet days.

Dr. Gordon, of Exeter, has written on the injurious effects of wet winds in phthisis. There is no doubt that bronchitic, elderly, and some febrile cases do not improve then as they do in dry weather, but, with care, ordinary cases make fair progress. During bright, frosty weather patients do well. The climate of Scotland is not a choice one, yet patients in sanatoria there get on well. It is extremely doubtful if dry climates, which have drawbacks of their own, such as hot winds, dust, sudden changes of temperature, &c., are generally beneficial, except for a few months in the year. Hot, semi-tropical, or relaxing places are injurious.

There is no ideal climate for tuberculosis all the year round. It is quite certain that a large proportion of cases get well at home, notwithstanding spells of wet or sunless weather. The cosmopolitan observes that many vaunted climates have disadvantages, and that patients get cured in the most diverse places, so that some ignore the factor of climate. This is doubtless an extreme view. A place suitable for one does not benefit another, and these peculiarities are worthy of study. As a practical rule, the consumptive is best cured in the country in which he has to live. Those who migrate to sunnier climes do not always show the best results; in fact, some have returned with advantage to British sanatoria. Good authorities state that a patient who does not improve in a home institution is not likely to get well abroad. The drawbacks of expatriation, disregard of proper régime of treatment, &c., are apt to outweigh the advantage of more hours of sunshine. The means and social position of the patient also have to be considered.

3. *Rest*.—Most cases on admission require prolonged rest. The fatigue and excitement of the journey are apt to draw on the scanty balance of strength that remains to their credit, and they have to make up arrears of long standing. Few recognise the gravity of their condition, and some are rash or restless, ignorant or careless. Pyrexia and fatigue have been disregarded, and the excitement and distractions of business or pleasure have prevented the requisite repose. The breathing and heart's action have been unduly hurried by day, and by night the fever and cough have caused broken sleep. So the power of resistance is gradually undermined, until a timely surrender is enjoined.

In a sanatorium all this stress and strain is vigilantly stopped. All sources of excitement or worry are removed, and in the quiet routine, pure country air, with companionship of others undergoing like treatment, the patient soon learns the value of rest.

Various conditions, such as hæmorrhage, high temperature, debility, &c., indicate complete rest in bed or on a couch. The effect of proper rest on pulse and temperature is generally marked. Patients rest lying down during the hour before lunch and dinner, talking

(a) "Voyage of the Polar Star." By the Duc d'Abruzzi.

being discouraged. In some places the hour after meals is also thus spent. The patient thus comes to his food with quiet pulse and breathing; not hot or tired, and the process of digestion is undisturbed. Liegehallen, where a number of patients rest together, are objectionable, as preventing proper quietude during rest hours. However beneficial the sociability may be, there is the risk of undue talking, laughing, arguments, or even petty quarrels. Hence in some places the patients spend the rest hours either alone or two together. Experience shows that proper rest and quiet are essential. Some authorities have advocated constant rest, but this is not now adopted, except for some cases.

4. *Graduated Exercise.*—This is one of the most important factors of the treatment. Brehmer insisted on this, and his views bear the test of trial. There is hardly any way by which consumptives do more harm to themselves than by injudicious exercise. Extension of disease, hæmorrhage, increased pyrexia, &c., are thus caused. Hence exercise is given gradually and tentatively, at first a slow short walk on the level with frequent rests. The effect on temperature and pulse are noted. Discussion has arisen on the influence of exercise on temperature, and the relative value of rectal and oral temperatures. Dr. Kelynack (a) has shown that for all practical purposes in a sanatorium the oral method is trustworthy. Though a febrile condition generally indicates rest, some such patients do not improve until limited exercise is taken. Walking is the usual exercise, the pace being regular and slow, two to two and a half miles an hour. As strength is gained, the walks are longer. Gentle ascents are made, the uphill being at the beginning, and the downhill at the end, in order to lessen fatigue. The extent and direction of the walk are daily prescribed, according to the state of the patient and weather conditions. The force and direction of the wind are noted, and for weakly patients sheltered walks are chosen. Rests are frequent, at the furthest point of the walk, and if there is coughing or shortness of breath. To send patients together in chattering groups is objectionable. The direction can be varied to suit individual tastes and capacities, and a time limit is advisable. No weather should deter the stronger patients, but resting in wet clothes, or on wet seats or grass, is very questionable. At length, walks of several miles are given. Hill climbing is encouraged, and some simple form of drill, with breathing exercises, is beneficial when the disease is quiescent. An upright carriage when walking is advisable in order to correct the slouching gait to which consumptives are prone.

There is no doubt of the good effect of hill-climbing for suitable cases, and it is a feature of the treatment in some places. To apportion the due exercise to each patient requires experience and judgment. Most of them are inclined to overdo it, and if left to themselves to go wrong. Those who enjoy their exercise generally derive full benefit from it, but there are some who regard quiet country walks as a weariness to the flesh. The beneficial effects of graduated exercise are certain. The general condition is improved, useless fat got rid of, respiratory power and chest capacity increased, and muscular vigour accompanies gain in weight.

5. *Diet.*—The diet should be specially chosen. It should be plentiful, nutritious, and easily digestible, containing much proteid and fat. Three good meals a day are usually given, with a half to a whole pint of milk at each. Milk is also given at stated intervals. Fats such as butter, cream, honey, are insisted on, equivalent to about 2 ozs. of butter daily.

The appetite of most patients is uncertain and capricious; they are often fastidious and peculiar in their tastes. The disease being a wasting one, it is essential that much nutritious food be taken daily, hence firmness is required to induce them to take enough. Many will shirk it, if they can. Hence the doctor prescribes the food, and sees how they eat it. The indiscriminate stuffing once in vogue is now not

generally adopted. To fill to repletion dyspeptic patients with indigestible food to act as an emetic does not commend itself. Experience shows that less food in proper proportions gives good results. Much has been written on the value of different diets, metabolism in consumption, &c. Cases with active disease and pyrexia require careful and systematic dieting. Most patients soon eat well, and weak digestions improve. Such medicinal fats as cod-liver oil, maltine, &c., are very rarely required. The gain in weight is usually 1 to 2 lbs. weekly, or more, though too much value must not be given to this, for it is an uncertain index of real progress. The disease may progress, though the patient gets heavier. Even febrile patients will gain weight if they eat well and are kept quiet. More weight without condition is not the object of this treatment. Since many consumptives have bad teeth, and some pyorrhœa alveolaris, the services of the dentist are required.

6. *Medical Supervision.*—Some writers regard this as one of the main factors in the treatment. Dr. Knopf, in his practical essay on "Tuberculosis," records that "after visiting the chief sanatoria in Europe and America he is convinced that the tuberculous patient has the best chance of getting well only when he is under constant medical supervision." Dr. Latham, in his prize essay, quotes the statement of Solly to the effect that "in the beautiful climate of Colorado there is enormous difference in the mortality among consumptives under medical control when compared with those who merely consult a physician when they think necessary."

The disastrous effects of this lack of medical control are frequently seen in cases when admitted. In the patients' interest there must be discipline, which insists on essentials, but is lenient in minor details. A slavish adherence to routine or easy-going laxity are extremes to be avoided. To quote Dr. Latham, "The physician must be autocrat, his word must be law. He must be prepared to give his entire energy to the work, for, as Dettweiler has expressed it, "a sanatorium must be his religion, his politics, his despair, and his delight."

In charitable institutions where patients err through ignorance, the discipline must be strict. If located near a town, there is risk of temptation, frequent visitors, and violations of the canons of open-air treatment. In private sanatoria for the better class, to judiciously relax rather than tighten the bands of discipline, to lessen the irksomeness of restraint, while insisting on essentials, seem to be the aims of thoughtful medical superintendents. "All sorts and conditions of men" are found in sanatoria, and in ruling them common sense and tact are required. The office is no sinecure. To quote Dr. Knopf: "Consumption is not an easy disease to treat. It requires a thorough knowledge of the etiology, pathology, and therapy, and a familiarity with all the symptoms of the disease, but also a great deal of devotion and patience combined with strength of character." He leads the same kind of life as the patients; he sees them regularly, prescribes their food, exercise, and rest. He is their guide, philosopher, and friend, and encourages friendly rivalry in well-doing. He prevents undue excitement, and discountenances visits of talkative friends. Dr. Latham wisely warns against the temptations of sexual excitement. Among young, idle, well-fed patients some will be erotic. Hence some separate the sexes in their walks and rest hours. Sexual excitement in a consumptive is such a bar to recovery that it should be prevented. Anyone who knows a large sanatorium will admit that not only patients, but nurses and servants, want watching in this regard. Of course, careful discrimination is necessary.

The enforced idleness is apt to cause moral deterioration. The listless lounging and vacuous aspect occasionally observable may be prevented by quiet recreation or occupation. A gentle game of croquet or golf, a drive or picnic, help to vary the monotony. Various quiet games, hobbies like photography, botany, natural history, &c., may be encouraged. The

(a) *Brit. Med. Journ.*, October 24th, 1903.

musician or artist need not quite be debarred from his vocation.

The poorer class of patients need some work such as gardening or quiet household tasks. The whole subject needs careful consideration.

#### DURATION OF TREATMENT.

The usual time of treatment is three to six months, sometimes longer. When there are marked physical signs, the initial stage is past, and the extent of the disease is always greater than shown by physical signs (Gee). Tuberculosis is mostly a slow disease. The element of time is necessary for the process of tissue change which constitutes complete arrest. Trivial causes check recovery. Relapse is easy, unless care is taken, and many patients forget hygienic rules. Hence the prognosis should be guarded, and the optimism that predicts a speedy cure is found occasionally false.

#### UNFIT CASES.

Sanatorium treatment is not suitable for all tuberculous cases. The following may be held unfit:—

1. Age below puberty, or too old.
2. Bad family history and physique.
3. Temperament unfit. Irritable, neurotic, reckless, or alcoholic.
4. Chronic bronchitic cases, with tuberculosis.
5. Elderly dyspeptic cases.
6. Those who bear cold badly.
7. Advanced cases with extensive lesions.

Some sanatoria do not admit hopeless cases, which require comfort rather than cure. All unfit cases may be treated elsewhere by some modification of open-air methods.

#### RESULTS.

In Germany where statistics (a) are available, 85 per cent. of patients are improved, 16 per cent. unimproved, 0.8 died; only one-sixth did not recover their power of work. Those in the so-called first stage, with consolidation of one lobe or two half lobes, without cavity, show the best results. The statistics of English sanatoria are not available, but those published show similar results. Most cases except those in an advanced stage show great improvement. The early cases, as a rule, leave the sanatorium with no symptoms of the disease, slight physical signs, absence of bacilli in sputum, and robust in appearance. In more severe cases there is reduction of fever and pulse rate, less cough or night sweats, better breathing, and gain in weight and muscular power.

It is quite certain that results will be better still, as more suitable cases are sent and the unfit eliminated. The limitations of the treatment and the advantage of sending cases in the early stage are more generally recognised. Procrastination or a late diagnosis do not enhance the prestige of the medical adviser.

Many of those who complete sanatorium treatment are fit to enter again on the toils and joys of life, provided they follow some outdoor calling, free from arduous exertion or strain. Some have even gone back with impunity to employments where an open-air régime is impossible. Others are unfit for work, owing to lack of robustness, but with care and out-door methods they may live to old age. Occasionally the improvement is transient, but this is mainly due to carelessness, over-exertion, or bad hygiene.

Sanatorium treatment is no specific against tuberculosis. Many details are mainly empirical, but as its main principles inculcate a return to a natural life, instead of the artificial modes of so-called civilisation, even for its educational effect it is of great value. Hygienic treatment is beneficial for many other conditions of ill-health besides tuberculosis. Those of us who live the free open-air life, and who see the good effects of it on servants, nurses, and others, would not readily return to the doubtful blessings of ordinary life. The results of this treatment of tuberculosis far surpass any other, in the cure, arrest, or alleviation of one of the most prevalent of the "ills that flesh is heir to."

## British Health Resorts.

### IV.—BISHOP'S-TEIGNTON.

[BY OUR SPECIAL MEDICAL COMMISSIONER.]

AMONG the many fair villages of Devon which justly claim the attention of the health-seekers, Bishop's-Teignton deserves to occupy a foremost place. It is charmingly situated on the north side of the Teign Valley, about 200 ft. above sea level, and can be easily reached either from Teignmouth or Newton Abbot. An omnibus runs to Teignmouth (two miles) three times a day (fare 6d.). Teignmouth (20½ miles) can be comfortably reached from London by the Great Western Railway in about four-and-a-half hours. Passengers may also travel from Waterloo to Exeter by London and South-Western Railway in 3¼ hours, and thence proceed on the Great Western system. Bishop's-Teignton offers many attractions. It is sheltered from the cold winds on the north-east by the heights of Haldon, which rise to 800 ft.; this renders the village excellent as a winter resort. To the south are delightful views of the Teign Valley, while away to the west stand out the highlands of Dartmoor. On the east near at hand lies the open sea. The place is well exposed to sunlight, protected from trying winds, and combines something of the advantages of moorland breezes with the invigorating elements of a marine climate. The village is clean and picturesque, and over all there prevails a restfulness peculiarly soothing to the invalid and overworked worker. In these days of stress and strain, Bishop's-Teignton can offer rest for body and goes far to secure peace of mind. We particularly recommend it for the overworked, the convalescent, the invalid, and the aged.

Good apartments can be obtained in the village, but the visitor who is in search of health will do well to visit the well-known hydro, "Huntly," conducted by Mr. C. F. Carpenter. It has much to offer for the jaded and overworked. The situation is excellent, and the extensive grounds are well kept and afford views of great beauty. The house has been extended from time to time, and now an extensive suite of rooms exist, and they, together with the hall and corridors, are well heated in cold weather. Accommodation is provided for about forty visitors. Here a hygienic life can be lived which should allow of recreation of body and rejuvenescence of mind. Carefully selected baths, good food, pure air, attractive walks, pleasant drives, and much cheerful society supply the chief therapeutic factors for re-invigoration. Quiet outdoor pursuits may be enjoyed in plenty. A medical attendant provides for the requirements of the really sick.

Natural and artificial forces have combined to make Bishop's-Teignton a very desirable health station for an important section of cases requiring medical direction, and we have no hesitation in drawing the attention of medical men to its advantages.

## France.

[FROM OUR OWN CORRESPONDENT.]

PARIS, July 31st, 1904.

### TREATMENT OF LEAD COLIC.

PRUDENCE should be observed, says M. Feissinger, in the treatment of lead colic, for in reality the case might be one of appendicitis in which drastic purgatives would be dangerous. Hitherto, before appendicitis was as well-known as to-day, energetic purgatives were recommended, but with our present knowledge, to have recourse to them might sometimes be disastrous.

Saturnine poisoning does not always appear under the classical form; the diagnosis is sometimes difficult. The cardinal symptoms are not always all present; only one may remain—pain—while the others—constipation, vomiting, retraction of the abdomen, may be absent. Certain patients suffer from diarrhoea and

tympanitis, while in others fever is present. Contrary to the rule, certain colics are more painful to deep than to superficial palpation. Renal and hepatic colic are easily recognised by the special seat and character of the pain, but other affections might be taken for lead colic and of these, appendicitis is one of the most difficult to distinguish in chronic saturnism, especially as patients have been known to have attacks of both these maladies alternately.

Consequently, great circumspection should be observed in the treatment of lead colic. Drastic purgatives should be excluded; saline purgatives, sulphate of soda, or magnesia, associated with senna, should be preferred. But of all the evacuating agents, olive oil is the best, given either in one dose of six ounces or an ounce and a half each morning. Enemas of hot water have been recommended by Tripier, of Lyons.

To ease the pain injections of morphia are generally given, but opium pills, one to two grains in the twenty-four hours, are equally good. The Lyons doctors associate belladonna and antipyrine, the belladonna in one-third grain pills, three or four times a day, and from twenty to sixty grains of antipyrine in the twenty-four hours.

Where gastric intolerance is present, suppositories of opium and belladonna will be ordered; while the abdomen will be rubbed over with belladonna ointment. When the pain has ceased a mixture of sulphur and honey may be given and the patient recommended to take sulphur baths.

#### TREATMENT OF INFANTILE SYPHILIS.

The treatment, according to Dr. Leon de Keyser, should be at first maternal, that is to say, through the milk of the mother, who will continue the treatment begun during her pregnancy, and if this had not been prescribed, the mother will immediately be placed under the influence of the mercurial treatment. As to the child, rubbing in of mercurial ointment is very efficacious, and well borne, as it rarely produces salivation. The state of the skin, however, should be attended to, and the ointment should not be repeated on the same spot before a few days. Each day, one or two frictions should be made with a piece of flannel coated with a very small amount of mercurial ointment, ten to twenty grains. If diarrhoea sets in or the skin gets inflamed, the treatment should be suspended.

If internal treatment is prescribed, preference should be given to bichloride of mercury or calomel. The former is given in Van Swieten's solution or 1-1,000. From half to one drachm of this mixture might be given daily in milk, in three or four doses, and continued for months. Calomel gives excellent results at the dose of one-fifth of a grain three times a day. Monti prescribed—

Calomel,  $\frac{1}{2}$  gr.  
Lactate of iron, v. gr.  
Sugar, oz. iss.

Divide into ten powders, one to four daily.  
Taylor prescribes—

Bichloride of hydrarge,  
Iodide of potassium, iii gr.  
Syrup of orange water oz. ij.  
Five to ten drops three times a day.

### Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, July 31st, 1904.

In the *Therapie de Gejenwart*, Dr. Klienberger has a paper on

#### RECTAL FEEDING IN ULCUS VENTRICULI.

A wound, he says, heals up the more rapidly the less its

edges gape. An ulcer of the stomach heals the more rapidly therefore, when the stomach is contracted. It is in a state of greatest contraction when hunger is felt. Although there is difference of opinion among physicians how long the stomach should be kept empty, it is quite certain that no food whatever should be given by the mouth for some days after hæmorrhage from the stomach. It has been shown clinically that human life can be kept up for weeks by rectal feeding. Strauss mentions a case in which a man was fed exclusively by the rectum for seventy days. If a combination is made of egg, starch, and sugar enemata and oil subcutaneous infusion 2,000 calories may be given daily. No hyper-hydrochlorydia is present in an empty stomach. The usual nutrient enemata do not excite gastric secretion but it would be as well to omit red wine as an addition to the enemata.

It has been concluded by some that the abstinence cure is not sufficient, as not enough account has been taken of the anæmia present. The author looked into this question in the case of thirteen patients, who were being treated. The blood was carefully examined. The treatment had consisted in absolute rest for at least three weeks after the abstinence period; occasionally, infusions of 1,000 to 1,100 cc.m. of physiological saline solution were given. The nutrient enemata were given three times a day, and they consisted of 200 to 400 cc.m. of milk, two to three eggs, one teaspoonful of salt, one tablespoonful of sugar, and one of plasmon. If required, twenty-five drops of tincture of opium were added. An hour before the enema the bowel was washed out with water. Occasionally in the evening the saline solution was given by the bowel instead of subcutaneously.

The patients were under treatment for two months. Two died, one a girl, from hæmorrhage from the superior coronary artery, the other, a young man, from hydrochloric acid cauterisation; whilst drunk he had swallowed 130 grms. of raw hydrochloric acid.

The examination showed that during the extra-buccal treatment the body weight, blood pressure, and pulse curve sank moderately. The lowering of blood pressure did not usually exceed 30 mm. The hæmoglobin only appeared to diminish when the bleeding continued. The erythrocyte cells remained constant or rose slowly. They only sank to a corresponding degree when the hæmorrhage was severe and continuous.

The blood constituents in any case did not suffer from the rectal alimentation, and the power of the heart was not lowered.

At the Medical Society meeting Hr. Immelmann gave a short account of

#### LONDON'S LATEST EXPERIMENTS WITH RADIUM.

A bottle was filled with a solution of radium bromide and was brought into communication with another by means of a glass tube. In this second vessel were placed various objects, such as glass, iron, lint. He was able to show that by examination the properties of the radium were extended to these objects. Frogs and mice upon which these emanations acted, died and their cadavers were photographically active.

At the Society of Charité Physicians Hr. Heubner showed a child suffering from swelling of the eyes, constipation and wasting. It showed cachexia, swelling of the face and dyspnœa. On the right side of the chest was a projection that gave a dull sound on percussion. This reached in the axillary line to the fourth rib, and towards the left to the sternum. The physical condition was confirmed by radiogram. According to percussion there was no connection with the heart; the breath sounds over the dulness were weakened. As the dulness extended on expiration it

might be taken that the tumour was not in the lungs. It was therefore a mediastinal tumour, probably an enlarged thymus. The urine contained albumin. The swelling of the face was caused by stasis from pressure of the tumour on the superior vena cava. The paleness was due to the character of the blood, which contained 2,000,000 red blood corpuscles, 92,000 lymphocytes to the cubic centimetre, and a few polynuclear leucocytes. Nothing would do good except extirpation of the tumour.

Hrn. Kraus and Senator were of opinion that operation gave absolutely no prospect.

Another case shown was one of

#### INFANTILE MYXŒDEMA.

It was the case of a child of two, that although well nourished, at first developed slowly both mentally and bodily. For example, it had never laughed, it was not directly weak-minded, but weak in reaction and abnormally quiet. The face of the child was without form, thick, swollen forehead, narrow eyelid fissures, saddle-shaped nose, thick lips, and scanty hair. The skin was dry and thickened in many parts. The tongue was so much swollen that it appeared between the lips, and there was an umbilical hernia. The thyroid could not be felt at all. To the symptoms of myxŒdema of the adult were added faulty development of growth. It was like a cretin. The pulse was slow. The treatment consisted of Merck's thyroid preparation in doses of 0.025 to 0.05, and 0.1 grm.

There was a diminution in the formation of urea.

### Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, July 30th, 1904.

#### SUDDEN DEATHS IN TYPHOID.

At the Prague meeting, Velich drew attention to the recent expressions of Koch with respect to sudden deaths from latent typhoid, which he affirmed are very frequent. On that occasion he set down a rule that no patient should be released from isolation till no typhoid germs could be seen after three examinations of the stools. He assured the meeting that this was not an inconvenient regulation to establish, and that he had performed thirty-six post-mortems on such epidemiological sudden deaths, and found twenty-seven of them suffering from heart disease, old pleural attachments, kidney, liver, brain, or lung affections. The other nine were undefined cases which might come under Koch's description, but might be due to other causes as they had previously been confined to bed, to house, or hospital. Again, many cases of typhoid are so slight as to escape attention, and therefore distribute the disease more widely than the small number that may die. He thinks the vigilance of the past is better than the present proposal to confine a few unduly on suspicion.

#### BROMO-DERMA TUBEROSUM.

Samberger exhibited an epileptic, æt. 12, with a large swelling over the triceps brachii, depressed in the centre and covering an area as broad as the palm of the hand at the base, and tapering to the size of a florin at the apex. Around the upper margin were small pustules, while the whole growth tended to increase as is usual in these cases.

#### CONGENITAL PROMINENCE OF SCAPULA.

Jedlivka showed a girl, æt. 13, on whom he had operated for a projecting scapula on the left side. From the inner side of the shoulder blade a hard bony connection was observed that held the scapula up alongside the neck. In the operation to relieve the band Maydl found that the bony connection was firmly

incorporated with the sixth cervical vertebræ with a cartilaginous articulation at the scapular margin. On dividing the bony attachment at the arch of the vertebræ the spinal canal was opened and the dura mater injured. With careful attention the wound healed and the scapula fell to its normal level, leaving the patient strong, with a free movement at the shoulder.

He also showed a boy, æt. 10, who underwent a similar operation for the same sort of bony connection. Maydl considers this a supernumerary rib springing from the last cervical vertebræ and to remove the deformity nothing short of extirpating the abnormal bony connection is available. On looking through the literature on the subject, Maydl finds the term Sprengel's deformity attributed to this malformation, which was in existence and recognised long before Sprengel's time.

#### EXPERIMENTAL ENDOCARDITIS.

Prochazka then gave the Society a history of his efforts to produce endocarditis in animals. The question has often arisen is the microbe the chief factor in the production of endocarditis, or is it a second agent in the train of symptoms. Leube some time ago affirmed that the primary factor was a toxin that first acted on the endothelial cell and so weakened its vitality, that the secondary infection had an easy task in producing the inflammation.

In order to test this theory with practical facts Prochazka commenced his experiments by injecting ten dogs repeatedly with toxins of different microbes, till a condition of toxæmia was produced, when a specific microbe would then be introduced, into the blood by the veins with the hope of producing endocarditis. Of the ten dogs operated on only one survived the ordeal of the intravenous injection of the microbe, while all the control animals or those treated with the toxin recovered. Eight of the nine died from septicæmia and only one was free from endocarditis at the post-mortem; some were of the verrucous form, others assumed the ulcerative form, while others had both forms in combination.

None of those treated with the toxin treatment only had any sign of endocarditis. He therefore concludes that the toxins are the predisposing factors in the production of endocarditis. He pointed out that the same microbe may first provide the toxin in the blood till toxæmia is produced, and then with its actual presence excite the inflammatory endocarditis. This form of production is now known by the method of "Homogenic Infection," the other method is when a toxin has produced the toxæmia and a foreign microbe is introduced with the same result that it receives the name of "Heterogeneous Infection." It is worthy of note that the lesions induced in these animals were located to the same areas as described in pathological works, which is probably due to mechanical causes in the course of the endocarditis, such as rubbing or impact on the blood in the cardiac contractions.

Velich remarked that dogs were not suitable animals to perform experiments of this kind on, as 60 per cent. of the healthy dogs would be found to have endocarditis, more particularly if they were advancing in years and with urethral discharge.

Ottokar Kose expressed surprise at these results as he had experimented in the same manner with twenty-six dogs and only in one single case had he a positive result, and strange to say this was with a streptococcus culture!

Prochazka in replying, said that Velich must be confounding degeneration and atheromatous changes in the heart for acute endocarditis, which he recognised.

#### SULPHO-CARBIDE POISONING.

Vanysek showed two patients whom he had treated

for sulpho-carbide poisoning. The patients were engaged at an indiarubber works, where vulcanising was carried on in a very confined room, which was badly ventilated. The symptoms were motor enfeeblement of the lower extremities, paræsthesia, impotence, and mental depression. The objective examination revealed polyneuritis, tremor in hands and head, increased vaso-motor reflex which was present in the muscles also, muscular weakness, tactile anæsthesia of the skin, paræsthesia, and increased patellar reflex. One of them had the pseudospastic paresis of Nonne.

He further recorded the history of two other similar cases with Erb's symptom, expiratory retardation of the pulse with orthostatic tachycardia. These last symptoms he contended had never been recorded as being associated with sulpho-carbide poisoning.

#### MYÆSTHENIA.

Haveroch showed a few cases of progressive paralysis. One female knew she had it, but could not tell when it commenced. A young girl with myæsthenia could walk a short distance, but had to stand unable to move when the muscles were tired; if she held out her right arm her left became paralysed. There was no pain anywhere, only loss of motor power causing her to stand like a statue when the muscular power ran out. Her father was afflicted with the same malady.

## The Operating Theatres.

### GREAT NORTHERN HOSPITAL.

REMOVAL OF APPENDIX.—Mr. PEYTON BEALE operated on a man, æt. about 30, who had been admitted one week before with an acute attack of appendicitis. The patient had a history of three or four similar attacks previously. At the time of operation, all acute symptoms had passed off, but there was a swelling to be felt in the pelvis on the right side, and this swelling appeared to extend towards the inguinal canal. It was supposed to be a case of enlarged appendix, possibly bound down by adhesions. The abdomen was opened so as to expose the cæcum. This was brought out with considerable difficulty owing to adhesions binding it down in all directions. A large mass was found behind the cæcum involving the base of the appendix, which contained a small quantity of pus. This, Mr. Beale pointed out, was quite unexpected, seeing that all acute symptoms had been in abeyance for four or five days previous to operation. This pus was carefully washed away and the rest of the appendix sought for. There was considerable difficulty in finding it, as it was behind the cæcum and very much bound down by adhesions. When it was found it was seen to be firmly adherent to the spermatic cord, from which it was separated with great difficulty. Its various adhesions having been ligatured, the appendix was removed in the ordinary way and the wound closed. Mr. Beale said that this case was remarkable, first, because pus was actually found at the time of operation, although every acute symptom had passed off some days previously. This was, of course, not really a very uncommon occurrence, and he believed that in many of the cases of recurrent appendicitis a small abscess such as was found here persisted between the attacks and that, however long the surgeon waited before operating, he could never be certain from the patient's symptoms and general condition that pus was not present. It was of course encapsuled, but none the less must necessarily be a source of considerable danger when an operation for the removal of the appendix is undertaken. The case was of interest

secondly, he thought, because of the adherence of the appendix to the spermatic cord; he had not previously come across this condition, and at first sight it was not at all easy to realise that the structure was the spermatic cord, or to see how the appendix could have become adherent to it. Such a condition could, he supposed, only occur when the appendix was behind and below the cæcum, and of unusual length, as it turned out to be in this case. The patient had suffered no unusual pain, nor were there any symptoms beyond those of an ordinary recurrent acute appendicitis.

### NORTH-WEST LONDON HOSPITAL.

OPERATION FOR ACUTE INTESTINAL OBSTRUCTION FOLLOWING AN ACCIDENT.—Mr. MAYO COLLIER operated on a case of obstruction, the history of which was as follows:—Five days previously the patient, a publican, æt. 64, fell down the steps of his cellar on to some barrels. When examined by his local medical attendant, a fractured fifth rib was discovered. This was efficiently strapped and bandaged, and the patient advised to keep his bed. The following day the man felt very sick and vomited once or twice. There was complete anorexia and some commencing distension of the abdomen. This state of things becoming gradually worse, the case was admitted into the hospital. On admission the pulse was 120; there had been constant coffee-ground offensive vomiting for two days; the abdomen was enormously distended and tympanitic all over, and respiration was much impeded. The tongue was extremely foul, and the patient's general condition was very grave. Mr. Collier decided on immediate abdominal section. An incision was made above the umbilicus about four inches in extent. On opening the peritoneal cavity a much distended stomach protruded into the wound. The stomach apparently filled the whole upper part of the abdominal cavity. After puncturing with a fine needle and letting out a great quantity of offensive gas, Mr. Collier was enabled to introduce his finger into the peritoneal cavity above the small curvature. This was followed by the outflow of at least half a pint of blood and serum. The rest of the abdominal cavity was carefully explored, and the distended small intestine punctured in several places with a small needle, much gas escaping. Nothing abnormal was discovered in the rest of the abdominal cavity. Having carefully sponged the region between the pylorus and the liver, Mr. Collier closed the abdomen, and the patient was returned to bed. Mr. Collier said this was an extremely interesting case. The man was perfectly well before the accident, but yet symptoms of acute obstruction of the bowels supervened slowly after the fall. From the condition of the stomach, its acute distension, the coffee-ground vomiting, that took place before the operation, and the amount of blood in the upper part of the peritoneal cavity near the small curvature, this was evidently, he pointed out, a case of acute obstruction due to ileus following a blow in this region. The distension was so acute at the time of the operation, he said, that a considerable time had to be spent with a fine hypodermic needle in removing the gaseous contents of the bowels before the finger could be introduced to examine the abdominal cavity. This procedure was, in fact, he considered, the most important part of the whole operation, as it was in order to allow the bowels to recover themselves and to take off the pressure of the distended stomach.

From the time of operation the sickness ceased, the distension subsided, and the patient made an uninterrupted progress towards recovery.

REGISTERED FOR TRANSMISSION ABROAD.

**The Medical Press and Circular.**

Published every Wednesday morning, Price 5d. Post free, 5½d.

**ADVERTISEMENTS.**

ONE INSERTION:—Whole Page, £5 Os. 0d.; Half Page, £3 10s. 0d.; Quarter Page, £1 5s. 0d.; One-eighth, 12s. 6d.

Considerable Reductions from the foregoing scale are made when an order is given for a series of insertions. Terms on application to the Publisher.

Small announcements of Practices, Assistancies, Vacancies, Books, &amp;c.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

**SUBSCRIPTIONS.**

Subscriptions may commence at any period of the year. If paid in advance the cost is only 21s. per annum, post free. An edition is printed on thin plate paper for foreign and Colonial subscribers at 21s. per annum, post free, if paid in advance, or 23s. 6d. credit rate.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, AUGUST 3, 1904.

**THE BRITISH MEDICAL ASSOCIATION MEETING.**

THE Annual Meeting of the British Medical Association at Oxford has been the occasion of a more than usually brilliant gathering. This ancient University town has witnessed three such meetings since the first one held within its gates in 1835, attended by some 300 members. The progress of the Association has been rapid, and hundreds have been converted into thousands, so that the total number of members now reaches 19,000. The possibilities of such an organisation are incalculably great, and signs are not wanting that its fulness of power will shortly be exerted in defending the material interests of a profession that is sadly in need of protection. The president of the 1904 meeting, Dr. William Collier, found at hand a fruitful and interesting theme on which to base his discourse, namely, "The Growth and the Development of the Oxford Medical School." The teaching of medicine in that ancient seat of learning has been continuous since the great scientific Englishman, Roger Bacon, lectured within its walls. Since his days the names of such famous men as Linacre, Harvey, Sydenham and Radcliffe have become famous in connection with the study of medicine at Oxford. It is only within comparatively recent times, however, that science has been established on a firm footing in the University. Indeed, the revival of the Oxford Medical School may be said to date from the building of the museum in 1855. Since that date science has been simply revolutionised, a fact noted by Sir William Church in delivering the Address on Medicine. The last meeting in Oxford took place in 1868. It was only the year previously that Lister read at Dublin his paper on "The Antiseptic Principle in the Practice of Surgery." At that time the probability of the infectivity of tubercle was beginning to be esta-

lished. Sir William pointed out that the exact knowledge furnished by bacteriology and other branches of scientific research have had a greater influence on state or preventive than upon clinical medicine. Perhaps the most important part of his address was that which dealt with the relations between medical officers of health and the administration, both local and central. He instanced the attitude of the medico-political and public health committees of the Association in their proposed Bill to reform the public health department of the Local Government Board. The chief clause urged that the medical element should exercise greater weight and authority at Whitehall, and that "the medical officers of health throughout the country should be responsible to the Local Government Board, as well as to the local authorities." Under existing conditions the medical officer of health in the majority of cases simply courts dismissal if he acts fearlessly and progressively in the sanitary interests of the community. Other points in this most interesting Address will repay careful reading, not only by medical men, but by the outside public, to whom preventive medicine is a matter of profound and vital importance. Turning to the "Address on Surgery," we find an able address from Sir William MacEwen, who worthily maintains the illustrious traditions of Scotch surgery for brilliance and originality. The main part of his remarks he devoted to the choice of suitable material for ligatures and sutures, to their absorption and to the absorption of catgut and chicken-bone drainage tubes. Attention to details of this sort, it need hardly be remarked, are absolutely necessary to operative success. A novel feature in the Oxford programme was the delivery of a popular lecture by Dr. Ferguson, of Cheltenham. He chose as his subject, "Disease Germs," and discussed their nature and significance in disease, together with their appropriate preventive and curative methods. On the whole, the scientific side of the meeting has been well up to the average, while the social side of the annual meeting has been of an unusually brilliant character.

**SEASIDE THERAPEUTICS.**

THE seaside is probably the most ancient of health resorts. People have flocked to it in the hot weather from time immemorial in spite of difficulties of transport, ostensibly for the purpose of restoring their shattered energies, with results that, on the whole, may be assumed to have been satisfactory since the practice still obtains. The choice of a seaside resort is usually decided on grounds of expediency rather than of judicious selection, and the matter is perhaps not one of much importance so far as the healthy are concerned. When, however, we aim at obtaining certain definite effects from the air or in the water in disease it is necessary to form a clear idea of what we require and the likelihood of obtaining it. All seaside resorts are not alike, therapeutically speaking; far from it, a point that is clearly shown

in the communication (a) which we publish on "Seaside Therapeutics." Apart from certain general characteristics, such as uniformity of temperature, atmospheric density and moisture, freedom from dust, and comparative richness in oxygen, the curative properties of seaside resorts vary greatly, accordingly as they are, or are not, protected from wind, are sunny or otherwise, and, last but not least, according to the configuration of the neighbouring country, whether wooded or bleak. Each description of resort has curative qualities of its own, but no one resort is suitable for all classes of patients, even if we exclude those whose morbid predispositions are such as to render residence in the vicinity of the sea undesirable or injurious. The popular practice of sending people with "weak chests" to the seaside is fraught with many, to the physician, obvious risks, and the wise would no more think of adopting this course without obtaining medical advice thereon than they would administer particular medicaments on their own responsibility. It is not a matter of indifference, it cannot truthfully be asserted that if it does no good it will, at any rate, do no harm. The perturbations induced in the human organism by transfer to the seaside, especially before the system has had time to become acclimatised, are often very marked, and, in the delicate, may be attended by grave discomfort, if nothing worse. In the article to which we have referred, sundry practical data are given on which an opinion can be formed as to the suitability of a particular resort in individual cases, for nothing should be left to chance. Medical men as a rule are familiar with the general principles that underlie what may be termed seaside therapeutics, but what they lack is a classification of seaside places into categories according to their local climate and topography. There is room, indeed, for a guide to watering-places, not based on the claims advanced by those who are interested in their future, but reasoned out in accordance with the well-known principles of climatic therapeutics. Much useful work has been done in this direction by the committee of the Royal Medical and Chirurgical Society, but its reports are not accessible to the general public or even to members of the medical profession. Were it not that the curriculum is already over-crowded, we should be tempted to suggest the propriety of requiring some knowledge of balneotherapeutics, a branch of medicine which for some reason has been persistently neglected in this country, though highly appreciated elsewhere. To some extent, however, in late years the gap has been filled by the Balneological Society of London.

#### SUPERSTITION AND PSYCHOLOGY.

THERE has been much fluttering in the journalistic dove-cots over the remarkable dream that Mr. Rider Haggard has thought fit to publish to the world in a letter to the *Times*. Probably, there are few people to whom the circumstances

are not now familiar, but it may be well for the sake of those who have not fully acquainted themselves with its details to recapitulate them briefly. One night Mr. Haggard was awakened by his wife from a confused nightmare in which uncomfortable sensations such as those of drowning prevailed. Between the time of his being aroused and the time that he became fully conscious he dreamed that a favourite dog was lying among rough growth beside water, and that his (Mr. Haggard's) personality was rising out of the dog. The dog seemed to be trying to speak, but could not, yet it somehow conveyed to Mr. Haggard that it was dying. Then he awoke. The subsequent facts may be summed up by saying that the dog appears to have been run over by a train some three hours before Mr. Haggard's dream, and to have fallen over a railway bridge into some water, where he was discovered two days later by strangers. The exact time of its death cannot certainly be determined, but the general probabilities point to the accident having occurred well before the dream; the only alternative being is that it was killed at least twenty-four hours after the dream, as a Sunday, on which no trains ran, intervened. These, then, are the facts, and it is quite extraordinary the hubbub that they have created. Making an allowance for the dreamer's personality being that of a popular novelist, and for the approaching advent of the "silly season," there remains a large gap in the reputation of the Britisher for stolidity that it is difficult to fill up. In every country there exists side by side with the work-a-day individuals a complement of idle quidnuncs, and these are only too glad of any trifling passing sensation, but when journals of the acumen and culture of the *Spectator* take to debating seriously the solution of the "mystery," it is excusable to remark that they might be better employed. Medical men are frequently accused of materialism, and no doubt scientific training tends in that direction, but what is valuable in scientific training is that it never encourages its followers to fly to supernatural or præter-natural explanations for phenomena, till they become inexplicable on natural hypotheses. The gain that the scientific method has been to medicine is inestimable, and not the least of its benefits has been that it has entirely eliminated the crudities of demonism and supernatural interventions from its pathology. Fortunately for themselves, sick persons at the present day, even if they cannot be directly cured, are spared the infliction of undergoing painful and even brutal rites such as were entailed by the practice of exorcisms. To find, then, so small an impression has been made by science on those of our fellow-workers who represent in journalism much that stands for the best in thought and culture, that, in this year of grace, the *Spectator* gravely brings forward a theory of the migration of the spirit during sleep to account for Mr. Haggard's dream, is, to say the least, disappointing. The physiology of sleep—the diastole of the brain, as oster has called it—is admittedly not fully

(a) See "Original Communications," page 112.

understood, but on the analogy of other tissues, it is only reasonable to assume that the most highly differentiated of all tissues needs its periods of rest, and the cortical cells of the brain might be naturally expected to require longer time for recovery from stimulation and irritation than more lowly organised structures such as the cells of the salivary glands or pancreas. The disturbances of the function of sleep, like the disturbances of any other function, are dependent on some structural vice of the tissues, and the phenomena of the hypohypnotic state—dreams, somnolentia, night-terrors and so on—have, naturally, a psychical as well as an organic side. In dreams ideas and emotions succeed one another by association, but without correlation, and judgment and reasoning power are in abeyance. An idea has only to be conjured up for a train of associated ideas to follow inconsequentially on its heels, and thus we get the juxtapositions of persons and places taking place in dreams that make food for mirth when we sit down to breakfast. A nightmare, such as Mr. Haggard had, is a hypohypnotic disorder, and practically always is attributable to some more or less remote irritation; it would be interesting in his case to find out whether he was subject to nightmares, and whether he has any temporary or permanent source of irritation. That he presented some symptoms of somnolentia we should be inclined to deduce from the fact that his wife woke him up, which she was not likely to do in the middle of the night unless he was exhibiting motor phenomena of some sort. Then, too, we have the admission of the telepathists and the spiritualists that Mr. Haggard's experience of "communication" with an animal is almost if not quite unprecedented, together with the fact that the dog, if dead, must have been so for at least three hours, for it is inconceivable that a dog that had been run over by a train could live many minutes. Is there anything in the whole story that is not quite reconcilable with the simple hypothesis that Mr. Haggard had an ordinary nightmare dependent on usual causes, and that somewhere about the same time his dog happened to be killed? The admittedly unique character of the dream is in itself strong evidence of coincidence, and we think it a vast pity that fantastic superstitions should be indulged in by influential journals, superstitions that tend to put back the hands of the clock from 1900 A.D. to 1900 B.C., or earlier.

### Notes on Current Topics.

#### School Dentistry.

THERE is no disguising the fact that in matters of school hygiene and medical supervision we in this country have much to learn. THE MEDICAL PRESS AND CIRCULAR has constantly striven to enlist the interest of the profession in this topic, which is rendered doubly important now that the influence of school life and habits is being recognised as one of the most powerful

factors of the national physique. The need for the appointment of an inspecting medical officer who should preferably be attached to every Board and Council school in this country has many times been emphasised in these columns, and we offer no excuse for once more bringing the subject forward. This time, however, it is to call attention to the excellence of the arrangements adopted in several German and other Continental cities by which the teeth of school children are regularly and systematically inspected. The statistics of our own London School Board examiners have shown conclusively that bad teeth are alarmingly prevalent among the scholars of all ages and both sexes, and a similar state of affairs has been found in Darmstadt and Stuttgart. In both these towns a fully-equipped dental room has been fitted up in one or more of the central schools in which the teeth of each child are examined and appropriately treated by extraction or stopping by a duly-qualified dentist, who gives his whole time to the work. When the evils which result from the presence of carious teeth upon the digestive system, and also their liability to produce toxic symptoms, such as those of pernicious anæmia, are remembered, such measures as these are the reverse of extravagant, they are salutary in the extreme. England must not be behindhand in giving her children the benefits of modern science which can no longer be considered as luxuries but as actual necessities.

#### The Treatment of Gastropstosis.

THAT malposition of the stomach which results in a downward displacement of the whole organ is more common than is usually supposed. Meinert, of Dresden, found the condition in from 80 to 90 per cent. of all young women and girls. Deformities of the lower part of the chest, whether natural or acquired, are among the most potent causes of a falling of the stomach. Later in life, the condition may be associated with ptosis of the whole abdominal viscera, then known as Glénard's disease, in which there is supposed to be a general relaxation of the suspensory folds of peritoneum, which normally support the stomach and intestines. Movable or floating kidney may be present at the same time. A certain amount of gastric dilatation frequently accompanies its displacement, and this again is sometimes definitely connected with disorders of the nervous system. Dr. A. Rose, of New York, (a) describes cases in which migraine was associated with gastropstosis. As regards the treatment of this troublesome condition, special attention to the mode in which the gastric functions are performed is necessary, while lavage, systematically employed, may be useful in helping to overcome the accompanying dilatation. The increase in size of the abdomen and consequently in the capacity of its vessels has an important bearing upon the whole circulation, for in conditions of arterio-sclerosis there may be so much blood contained in the splanchnic reservoirs that the nutrition of the

(a) *Medical News*, July 16th, 1904.

brain may be seriously compromised. It is not enough in such cases merely to provide an abdominal belt. What is required is an actual diminution in the size of the stomach itself. Dr. Rose finds that strapping, intelligently applied over the abdomen, will, in many cases, brace up the organ, so that its true secretory functions are once more restored. In selected cases, massage over the same area might also be of service.

#### Hospitals and Post-mortems.

THE recent performance of a post-mortem examination unauthorised either by the friends of deceased or by the Coroner, has given rise to some public comment. In this particular case, a child swallowed a cherry stone and was taken to the hospital, where tracheotomy was performed. The acting house surgeon, who operated, subsequently conducted a post-mortem examination with the help of the Registrar of the hospital. At the first hearing in the Coroner's Court, he stated that it was not usual to obtain the permission of the friends to a post-mortem, an assertion that later was emphatically disproved. The reason for this belief may probably be found in the fact that some of the large hospitals make it a condition of admission that a post-mortem examination shall be made, if considered necessary, in case of death. Were it otherwise the progress of medical science would be lamentably handicapped. In poor-law infirmaries, where consent of friends is necessary, a post-mortem examination may be stopped by a person who is not even related to the deceased. In that way, the final pathological test of many obscure illnesses has been lost, and the sum of human knowledge has been the poorer. It is impossible totally to disregard sentiment even in its most unreasoning forms, especially when linked with affection, but it smacks of ingratitude when a post-mortem examination that may furnish information of value to the living is denied by the friends of a hospital patient.

#### Fatty Degeneration.

FOR many years one of the points emphasised in the differentiation of fatty infiltration and fatty degeneration was that the origin of the fat in the former case was extra-cellular and in the latter intra-cellular. This distinction was due to Virchow, who explained the formation of fat in fatty degeneration as being due to some combination of the non-albuminous constituents of the cell, splitting of the cell into albuminous and non-albuminous groups having first taken place. It is curious that, as long as this view has held the field, transcribed by one authority from another, the evidence in its favour has been so slight, while the objections to it are many and strong. On the other hand, Recklinghausen showed that both in causation and morphology fatty degeneration and fatty infiltration presented many common features, while, on the other hand, Pflüger maintained that chemically there is little basis for the assumption that fat can be formed by the aseptic

decomposition of proteid. The experiments of Rosenfeld, too, with phloridzin poisoning in dogs fed with mutton fat, showed that the fat occurring in degeneration exhibits the characteristics of the fat taken in the food, or, in other words, that the fat deposited in degeneration and in infiltration are of the same nature. In view of such facts, the current opinion among modern pathologists is somewhat adverse to Virchow's doctrine, and there is a tendency to discard the term "degeneration" as assuming a theory no longer admitted. At the same time it is to be remembered that the process is associated with degenerative changes in the cell, and, whether quite accurate or not, the distinction between "fatty infiltration" and "fatty degeneration" is still a convenient one.

#### Hadwen v. Price.

THE result of the action for libel brought by Dr. Hadwen, the Gloucester antivivisectionist, can hardly be regarded by him as encouraging. The trial arose from the remark made by the defendant medical man, Price, to the effect that a child certified by Dr. Hadwen to have died from brain fever might possibly have died from small-pox. Adverse comment of any kind from one practitioner upon the opinion of another is at any time undesirable, even when the person criticised holds views such as homeopathy and antivaccination, that have been tried in the balance of orthodox medical practice and found wanting. In this instance the person aggrieved was awarded a farthing damages by the jury, and the judge ordered that each side should pay its own costs. The actual costs paid by Dr. Hadwen are stated to have been over a hundred pounds, a sum that has been amply covered by a cheque for £154 17s. 11d. collected by Lieutenant-General Phelps, the president of the Antivaccination League, and presented to Dr. Hadwen.

#### The Risks of Professional Life.

AMONG the various risks attached to the daily life of the medical man, not the least serious is that of being attacked by a lunatic patient. Many are the experiences on record where the medical attendant has had to fight for his life with some madman, who has probably locked the door and perchance thrown the key into the fire or out of the window. Recently a startling experience of this kind fell to the lot of Dr. Shuter, of Chiswick, happily without serious results, so far as he himself was concerned. He was called to an engineer, whom he saw in his bedroom in an excited condition, and who announced the fact that he was going to blow his brains out. The man thereupon whipped out a revolver and pointed it at the doctor. The latter told him to put the weapon down, but without effect, for he immediately fired, and, missing his mark, lodged a bullet in the ceiling. An instant later he put the pistol to his forehead and blew out his brains. At the inquest the jury returned the usual verdict of suicide whilst of

unsound mind, and the Coroner complimented Dr. Shuter on his pluck. His medical brethren throughout the kingdom will warmly join in congratulating him on his escape from so terrible a jeopardy.

#### An Eventful Career.

MOST of us are familiar with the heroine of the melodramatic novelette who, at the same moment swallowed the deadly draught, discharged the revolver at her head, and plunged the fatal knife into her breast, leaped, with a wild shriek, from the dizzy height into the yawning darkness below, but "her hour was not yet." Strange as were her adventures, they were quite hum-drum compared with the career of a popular actor of the present day. Ludovic Branay, the famous Hungarian tragedian, has recently compiled statistical tables of his own stage adventures, and they are worth quoting. In his professional life he has been married 1,721 times, and suffered death 1,120 times. "I was stabbed," he says, "61 times, killed by lightning 51 times, drowned 22 times, poisoned 166 times, beaten to death 86 times, died of heart disease 192 times, assassinated 109, and executed 133 times. Finally, I committed suicide 314, and died a natural death 55 times." The list is interesting as showing the forms of death which appeal as picturesque to the theatre-going public. Yet we have seen somewhere that art should hold the mirror up to nature!

#### Lime-juice in Scurvy.

SURELY in no science is there less room for dogmatizing and appealing to canonical faith than in medicine. There is hardly an article of the medical creed that is not periodically taken up, trounced, and left to perish by the wayside, till it becomes exceedingly difficult to be certain that any real knowledge capable of being called "medicine" exists. From one's earliest days the efficacy of lime-juice in the prevention and cure of scurvy has been regarded as a point about which, however, many theories of scurvy might revolve, would still remain unmoved and immovable. Far from this being the case, from several sources lately news has been coming in that all lime-juice is not good for all scurvy, or that all lime-juice is not good for some scurvy. In which of these the truth lies it is not possible to say, for different observers speak differently. Government lime-juice is certainly not always efficacious, and both in the South African war and the Somaliland Expedition it was difficult even to get the men to drink it, so acrid and raw was its taste. And even when taken it is not always successful. In the Bengal jails there is a form of scurvy in which some patients have been freely dosed with Government lime-juice without effect, and in Somaliland similar experiences have prevailed. Fresh lime-juice certainly seems more efficacious and pleasant, but what the active ingredient is that gives it anti-scorbutic properties is not certain. A recent writer, Lieutenant Fleming Barnardo, of the Indian Medical Service,

recommends that lime-juice should be left out of the equipment of a military force, and that tabloids of citrate of potash and calcium chloride should be substituted. Undoubtedly much of the failure of lime-juice has been due to its gross adulteration. We hope this important matter may be thoroughly sifted.

#### The Hygiene of Paddling.

NOW that the seaside watering-places are daily becoming more and more frequented by holiday makers, the old question has once more arisen as to the advisability of allowing children to paddle in the sea. This is a subject upon which society papers and health journals love to dilate, and it is not surprising that many and contrary opinions thereon have been freely expressed. The practice of paddling, so dear to the child's heart, cannot be condemned wholesale, because a few cases of illness have been traced to its influence. The danger of contracting rheumatism in this manner has probably been much exaggerated. In this, as in other things, the exercise of common sense will prevent gross indiscretions. The chief dangers to guard against in paddling are cerebral congestion and chill. One of the reflex effects of cold water, especially when applied to the extremities is to produce a certain amount of congestion in the internal organs. In cases where the stability of the cerebral circulation is upset by slight causes, as in epileptic conditions, it might then be inadvisable to stand about for long periods in the wet. The direct effects of the sun's rays in very hot weather have also to be considered, and it is certainly unwise to allow young children to run about all day with no covering upon their heads, whether their feet be in the water or not. A good straw-hat or sun-bonnet will act as a sufficient screen, so that anxiety should be removed upon this point. A child who is perspiring freely should not, of course, be allowed to paddle, as it is quite easy to contract a chill in that way. Provided these simple precautions be observed, there can be no harm whatever in indulging in this particular form of amusement, which is specially associated with a visit to the sea-side. We do not, of course, refer to cases in which there is obvious organic disease present of the heart or brain, when greater care and circumspection will be needed.

#### Municipal Medical Attendance.

SWITZERLAND, the birthplace and centre of municipal life, seems determined to apply the social contract system to medical attendance. It has recently been announced that the Canton authorities have resolved to levy a new annual tax of 3s. 6d. per head, to be called the "Zurich Medical Tax." In return for that contribution the inhabitants will be entitled to free medical attendance from State-paid medical officers. There is much to be said on both sides of this new departure. So far as the public are concerned, they are likely to get more equality of practice as well as more scientific treatment, the latter

likelihood being due to the absence of any incentive on the part of the medical man to humour the fancies of his patient. Clearly it would not do for the patients to have the right of choosing their medical attendant, for in that case the popular man would be overwhelmed with work, for which he would obtain no corresponding advantage by way of emolument. After all, there is not such a very great difference between the Swiss municipal service and the British medical club service. Neither the one nor the other is likely to make any serious inroad upon the income of the medical man in high-class private or consulting practice.

#### The Progress of Sanitary Science.

THE increasing amount of interest taken in sanitary affairs generally, is shown by the large number of delegates from the home counties and foreign governments who attended the twenty-second Congress of the Sanitary Institute at Glasgow. In the course of his Presidential Address Lord Blythswood remarked that science "saved those who were a burden to themselves and a danger to others." Such, indeed, is the whole aim of medical science of which hygiene forms so large a part. If we look around at the work done by such bodies as the Sanitary Institute and the Royal Institute of Public Health, the Congress of which was held simultaneously at Folkestone, we cannot fail to see advance and improvement in every direction. The care and treatment of the consumptive, the prevention of consumption itself, the prophylaxis of infectious diseases, the health of school children, the examination into the alleged causes of physical degeneration, and the adoption or recommendation of means whereby it may be prevented when proved to exist—these are only some of the items of a gigantic, scientific programme which is gradually, though slowly, being carried out. The education of the masses in sanitary science takes time, and old prejudices cannot be overcome in a day, nor even in a generation. It is a significant fact, however, that the death-rate in Glasgow has been reduced by one-half through the introduction of sanitary measures, and this in the face of an ever-increasing population. A similar result has also taken place in the case of other large cities. With regard to the smoke nuisance, the President of the Sanitary Institute expressed the hope that the subject would be taken up in earnest during the coming session, and that the conservatism of manufacturers would not be allowed to stand in the way of a plentiful provision of pure, unadulterated air for the workers in populous centres.

#### The Dangers of Iced Drinks.

THE weakness of human nature is such that a certain amount of pleasure is always experienced in rushing to extremes. The sensation of ice-cold liquids careering down the gullet and benumbing the pharynx is so delightful in the hot weather that minor inconveniences in the shape of toothache, loss of appetite, or gastric pain are not minded. More cautious individuals try to

be a little careful both as to the nature of their frigid draughts, and also as to their place of purchase. Happily for the health of the poorer population, the introduction of more stringent by-laws respecting the ice-cream traffic, the danger of contamination of these refreshing commodities has been greatly minimised. We are not, as a rule, in the habit of consuming iced liquors the whole day long, but there is no doubt that in hot weather a considerable proportion of the cases of dyspepsia that occur owe their origin to such practices. If drunk when the system is much overheated, or weakened by over-exertion, and in large quantity, the immediate effects upon the circulation may be alarming. This fact is pretty generally known, but one or two cases in which the result of the ingestion of a large amount, suddenly, of ice-cold liquid into the stomach has been fatal may sometimes be heard of during a spell of tropical heat. There is another danger of a more insidious character, because, as a rule, unsuspected, attending the consumption of iced drinks, and that is the ice itself may contain germs of disease. Natural ice is not always free from impurities; in fact, it is frequently grossly contaminated, but that which is artificially prepared may be actually infected with pathogenic organisms. The recent occurrence of several cases of enteric fever in the Lausanne district has led the municipal authorities there to issue warnings to excursionists and others against drinking iced or snow water, or any beverages which have been mixed with ice. This is by no means an isolated instance of the danger that may lurk in an innocent-looking lump of ice.

#### Phosphoric Acid in Gastric Medication.

IN the many different clinical types of dyspepsia it is often a matter of no small difficulty to select a remedy that will not only relieve subjective symptoms, but will also enable the gastric juice to act with the greatest efficiency. Sometimes it is alkalies, and at other times acids which bring about the desired result, or it may be necessary to combine one of these with some preparation of pepsin itself. In states of hyperchlorhydria the administration of acids is obviously not called for, but, unless a chemical examination of the gastric contents be made, it is not always easy to detect the minor degrees of hyperacidity. It is a significant fact that the gastric juice normally contains acid, and that a mineral one, and it is probably for this reason that the dilute nitrohydrochloric acid has long been a favourite ingredient of many so-called indigestion mixtures. When an acid is given internally, it acts to some extent as an antiseptic, it excites the flow of the normal digestive juices, and it assists the action of the stomach ferments. M. A. Martinet (a) finds that phosphoric acid is in many ways preferable to the dilute nitric or hydrochloric acids. In the first place it is a less powerful acid, and it

(a) *La Presse Med.*, July 23rd, 1904.

is neutralised in the intestines with the formation of sodium phosphate. It is not irritating to the delicate renal epithelium, and by the kidney it is eliminated as the acid sodium phosphate, the salt to which the normal acidity of urine is due. The ordinary mineral acids sometimes cause irritability of the stomach, which phosphoric acid is said not to do, while it is also credited with certain tonic effects upon the nervous system. This latter function is not improbable, when we consider the rôle played by phosphorus itself in the nutrition of nervous tissue.

#### Bathing During Menstruation.

A CARDINAL maxim of all gynecologists is that no risk of a chill should be incurred by women during the menstrual period, and in connection with this a very widespread tradition has sprung up that the daily bath should be given up whilst the monthly flow continues. Dr. Clifton Edgar, of New York, has lately circularised the leading gynecologists as to their views on the matter, and has classified their replies. The general consensus of opinion seemed to be that bathing was largely a matter of habit, and could be practised by its devotees with impunity during menstruation, but that this did not hold with all women, and in any case sea-bathing should certainly be eschewed. The daily tepid sponge bath (85° to 92° F.) should be encouraged, for besides being innocuous, it was demanded by the rules of hygiene. If omitted on the first day, practically all women could take such a tepid bath on the second or third day after the flow was established, and, finally, that in most women the habit of taking a tepid shower or sponge-bath could and should be acquired. With these opinions we generally concur, for they are eminently sane and rational, and it is a pity that so necessary an adjunct to cleanliness at the time when it is most needed should be omitted through a mistaken notion of its harmfulness.

#### The Danger of Public-Houses.

It has long been known, and the insurance offices have noted the fact in a practical fashion, that the public-house trade is an unhealthy one for the employés. The great danger naturally is that of alcoholism, but in the wake of alcoholism comes tuberculosis, and the mortality of people engaged on licensed premises from tuberculous disease of the lungs has always been high. Dr. Allen, Medical Officer of Health for Westminster, in his last annual report, points out the mechanism by means of which the connection between the two is probably effected. Persons disabled by consumption from pursuing their occupation turn naturally to the public-house to while away the day, and, as is the habit with public-house *habitués*, spit freely on the floor. In one public-house in which the consumption rate was especially high, Dr. Allen took specimens of the expectorated matters on the floor of the bar, and had them

stained for tubercle bacilli. The bacteriologist reported that the organisms were present and in an active condition. Now, it is no difficult matter to understand how in a hot, stuffy, ill-ventilated public-house, whose bar is thronged with goers and comers all day and half the night, expectorated matters become dried and pulverised. Converted into dust, they are freely inhaled by those whose constitutions are apt to be impaired by the close air and indulgence in alcohol, so that the conditions for breeding tubercle could not be more favourable. Dr. Allen suggests that some adequate disinfectant should be used to moisten the floor of the bar, so that the dust, with its bacilli should be kept from rising, and the organisms themselves gradually killed. This plan may modify the evil, but so long as people persist in frequenting premises where every condition is adverse to health, so long will they render themselves liable to the inevitable consequences.

#### Prevention of Perineal Rupture.

ONE of the boasts of the present age, and especially of the present moment when health congresses and sanitary banquets are in full swing, is that preventive medicine is making unprecedented strides, and that disease and death are being kept at arm's length through the science of hygiene. But a perusal of trans-Atlantic literature casts somewhat of a blight over the rising spirits of the enthusiast, for it impresses him with the saddening reflection that he is but a babe in these matters, whilst his fellow Anglo-Saxon scientist is forging ahead. Let him, if he doubt this, glance at the proceedings of the annual meeting of the American Gynecological Society in May last, and he will find how far he is from reaching the pitch of anticipation in obstetrical science that has been there attained. Dr. Laphorn Smitt, of Montreal, spoke of the importance of perineal ruptures during parturition, and showed how even small tears are liable to become the seats of septic infection and absorption. Besides this immediate danger, large tears involved the probability of prolapse of the pelvic organs from weakening of the support normally maintained by the flow. If ruptures occurred, they should be sutured at once, but far better than waiting till the tear occurred, was to anticipate it. This might be best accomplished by putting in the stitches before the head passed the perinæum, whilst the patient was anaesthetised, and the parts in their proper positions. Two or three sutures having been inserted, they should be caught loosely in Peau forceps, until the placenta was delivered, and then quickly tied so that the apposition of the edges might be as accurate as possible. Dr. Laphorn Smitt evidently takes a gloomy view of his skill in preventing rupture. We wonder what he says to the patient whose perinæum remains intact, and who finds sutures and forceps fastened thereto after the completion of labour. The situation must be a rather delicate one.

## PERSONAL.

THE King has been graciously pleased to confer the decoration of the Royal Red Cross upon Miss J. Bradbury, Miss C. Addison, Miss S. Ruiter, Miss E. M. Early, in recognition of the services rendered by them in tending the sick and wounded at the Volunteer Hospital, at Intombi, during the late war in South Africa.

THE Marquis of Ripon, K.G., President of the Western Ophthalmic Hospital, Marylebone, London, recently opened a new out-patient department, which has been added to that institution at a cost of £3,800.

DR. W. H. SYMONS, the well-known medical officer of Bath, has presented a local institution with an excellent geological model of Bath and surrounding district.

MR. JOHN F. SYDNEY COLOHAN, of Blackrock, has been appointed a Justice of the Peace for the County of Dublin, on the recommendation of the Right Hon. the Earl of Meath.

ON the 24th ultimo, Dr. John Keys, of Dublin, was presented with a handsome testimonial of silver plate and other valuable articles on the occasion of his recent marriage.

THE Earl of Radnor, in his presidential address at the Folkestone meeting of the Royal Institute of Public Health, dwelt chiefly on the necessity of better sanitation of country in its relation to town supplies.

MR. ALFRED WILLETT will be presented with a gold medal in recognition of his long and valuable services to St. Bartholomew's Hospital, and a silver "Willett" medal will be awarded annually to the candidate attaining highest marks in the Brackenbury Surgical Scholarship.

DR. H. G. HAYMAN, delivered a most interesting address as President of the annual meeting of the Western Counties Branch of the British Dental Association, held last week at Frome.

DR. G. POČOCK GOLDSMITH, of Bedford, was entertained at dinner last week by his fellow medical practitioners on the occasion of his retirement from practice. For thirty years Dr. Goldsmith was actively engaged as surgeon on the staff of the Bedford Infirmary, and was afterwards appointed consultant surgeon.

SIR MICHAEL HICKS-BEACH recently opened a large and handsome home for the nurses of the County Infirmary at Gloucester, and delivered a most interesting speech upon that occasion.

DR. ERNEST CLARKE, Chandos Street, Cavendish Square, London, while passing through Walton last week on a motor-car, was struck on the neck by a shot apparently from a gun, but no trace of the offender can be found. Dr. Clarke, fortunately, was not seriously hurt.

THE Middlemore triennial prize for the best thesis on ophthalmology was presented in the Shelbourne Theatre at Oxford, at the inaugural reception of the British Medical Association, to Mr. John Herbert Parsons, M.B., B.S., F.R.C.S.

DR. THOMAS A. DOWSE has been appointed Government Medical Officer at Levuka, Fiji, and Dr. Charles E. Maguire, District Medical Officer of Suva.

SIR THOMAS BARLOW, M.D., and Dr. A. D. Waller have been appointed representatives of the University of London at the International Congress of Medicine to be held at Lisbon in April, 1906.

MR. A. B. KEMPE, Secretary of the Royal Society, represented that body at the funeral of the late Sir John Simon, on Wednesday last.

## Correspondence.

[We do not hold ourselves responsible for the opinions of our Correspondents].

## THE DIMINISHING BIRTH-RATE.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Dr. Drysdale writes:—"Economically, it is out of the question for the people of any European State like ours to think of having large families with impunity." It would be very interesting if he would attempt to establish the truth of this statement by an examination of the economical position of France in relation to the population question—France, whose people have carried to a logical conclusion the ideas developed by Dr. Drysdale and his school. France, with the most fertile soil—a soil capable of sustaining many more millions than at present subsist upon it—the most magnificent climate, and the most intelligent populace of Europe, has not enough men for her home requirements. Her numbers are kept up only by immigration of Italians, Swiss, and Germans. She cannot spare, and virtually she does not send, any emigrants to occupy and develop the vast possessions misnamed Colonies—even to beautiful Algeria close to her shores—which she has acquired mostly within a few years; so that to the onlooker these seem but a useless burden, expense, and source of weakness to the State. It cannot be doubted that these territories will in time either by peaceful or warlike conquest be overrun and acquired by stronger and more prolific races, white or yellow. France is already one-third less in population than Germany, and the disparity will soon be much greater, so that the resumption of her once dominant position in Europe seems for ever hopeless. Besides limiting the population, the French are, in fact, carrying out a gigantic system of artificial selection which, whilst ensuring the survival of the first born and their progeny, ensures at the same time, to a large extent, survival of the comparatively unfit. It is not prudence alone which guides the modern French parent, but the narrowest form of anti-social egoism, the egoism which sacrifices everything in pursuit of ease and pleasure, and regards toil and self-sacrifice as the sources merely of pain and unhappiness. The population question in later generations has become invested with a meaning very different from what it expressed to the old political economists like Malthus, to whom Dr. Drysdale refers. With these islands getting their food supply from the remotest parts of the globe, and with those supplies inexhaustible, with Canada, Australasia, Africa, and other vast colonies crying out for population, and able to sustain countless millions, there should be for many a long year no useless surplus of men and women in Britain. Instead of attempting to limit population, statesmen and practical sociologists should rather direct their efforts towards removal of social diseases which keep so large a part of our people physically, mentally, and morally inferior. Our surplus population is composed of these inferior classes, mostly a burden upon the State, far below the standard fit for emigration to the rich lands beyond the seas where, among kith and kin, comfort or wealth awaits the efforts of every competent citizen.

I am, Sir, yours truly,

July 26th, 1904. A STUDENT OF SOCIOLOGY.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—It seems to me that both Dr. Taylor and "A Student of Sociology" have hardly appreciated the point of Dr. Walsh's admirable paper on "The Diminishing Birth-Rate." Dr. Walsh does not deny that a portion of the loss in births is due to the practice of methods that are admittedly artificial, nor does he advocate their employment as Dr. Drysdale does in your issue of the 20th inst. In their dislike of these practices Dr. Taylor and "A Student of Sociology" will have many sympathisers, but that is not the issue. The question is—Are artificial methods for preventing conception the cause of much modern crime, lunacy, and suicide, or are these methods a symptom of the same disease of the body politic as that which gives

rise to those other deplorable manifestations? Dr. Walsh's paper is irrefutable on this point. If artificial methods are the root cause of all this misery, I would put it to his critics that if one takes away that cause, the consequences disappear. Will they affirm that if every married couple in this England fell to producing as many children as time and opportunity gave them occasion, our gaols would empty, our lunatic asylums be converted into country houses, and *felo de se* be unheard of in the land? I have only to submit the issue in this form to show how untenable their position is. Dr. Walsh rightly deprecates sensational, alarmist statements and hasty generalisations, and pleads for a philosophic review of the situation. Let us admit that we are more likely to arrive at the truth by the latter method, and that, however much we may detest a particular symptom of a disease, it is not by attacking it that we shall cure the patient. The treatment must be specific and must be adapted to the sufferer; not symptomatic and arbitrary. We must in this matter weigh things in their due proportions, and not be like Gribouille, *qui se jette dans l'eau de peur de la pluie*.

I am, Sir, yours truly,

July 28th, 1904.

QUID PLURA.

#### MEDICAL MEN AND DRINK LEGISLATION.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—In your annotation on this question you ask, "Why should not medical men speak out their collective mind as to whether Mr. Balfour's alterations in licensing law are likely to increase the facilities for drinking amongst our countrymen." Having taken great interest in this question, I shall be glad if I may for one answer.

In the first place there can be no doubt the teetotal section is responsible for taking the initiative in setting the law in motion in lieu of following Shakespeare's advice to allow sleeping dogs to lie. And the initiative consisted in the high-handed conduct of certain (I presume) bigoted magistrates in depriving publicans of their licences without means or compensation and for no fault of their own. It is inevitable that in a procedure of this kind public opinion would demand a change of law. On the other hand had the teetotalers trusted to the gradual reduction and minimising effects of public houses and depended on the simple method of refusing new licences, except in urgent cases, although this method might require more patience and be less drastic, the law would then have remained quiescent. It follows, therefore, if the remedy offered by the new Act should eventually turn out (*Tempus omnia revelat*) unsatisfactory the teetotalers have themselves only to blame—their chief aim appears to consist in straining every nerve to embarrass the trade and inconvenience the public to the utmost, charging them with what they conceive to be an overstepping of the mark, and getting more than they bargained for; hence, with the aid of the Bishops who fire off their guns blindfold, they have attempted to wreck the measure by insisting on a time limit.

Now it is certain this time limit must result in one of two things. Either the licensing authorities would cease to reduce licences, there being no compensation to meet the difficulty—in which case the Act must become a dead letter—or if they did reduce without compensation, in response to the clamour of the teetotal section, only the most God-forsaken and demoralised specimens of humanity, who would not shed a tear if a licence were granted one hour and taken away the next, would occupy the throne. The question, therefore, is melted down, according to my view, to the choice of one of two alternatives—either the acceptance in future of Mr. Balfour's respectable publicans' measure without a time limit or the Bishops' unfair scheme with. I venture to predict the vast majority of medical men would prefer the former, and hence vote in favour of the new Act.

I am, Sir, yours truly,

CLEMENT H. SERS.

Brighton, July 22nd, 1904.

#### SOME OF THE NEWER METHODS OF OPENING AND CLOSING THE ABDOMEN.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—In this week's issue of your journal Dr. Alexander Duke writes that the method described by me for closing the skin wound in abdominal sections is in reality that employed by Professor Bozemann many years ago, to whom the credit for its introduction is due.

I am obliged to Dr. Alexander Duke for information as to the inventor of surgical leaden plates. I have known of them since my student days, and they have been conspicuous objects in all instrument makers' establishments for years.

These so-called Bozemann plates are placed at intervals across a wound, and are intended for the application of interrupted sutures; while the plate described by me extends the entire length of the wound, and serves as a means for tightly fastening a sub-cuticular suture. To Sir Kendal Franks is due the credit of applying the latter form of suture to surgery, and it certainly was not known at the time of the first appearance of the leaden plates, nor would it be possible to employ these with the sub-cuticular suture. Under these circumstances it seems needless to discuss the subject further.

Dr. Alexander Duke has betrayed amazement at my statement that silk-worm gut is capable of remaining for fourteen days in a wound without cutting out or exciting inflammatory reaction.

To me it is a matter of wonder that in spite of the many excellent post-graduate courses now obtainable a practitioner can be found so little conversant with the elementary result of modern aseptic surgery.

I remain, Sir, yours truly,

E. HASTINGS TWEEDY,

Master, Rotunda Hospital.

Rotunda Hospital, Dublin.

July 29th, 1904.

### British Medical Association.

SEVENTY-SECOND ANNUAL MEETING.  
OXFORD, 1904.

[SECOND ARTICLE.]

[BY OUR SPECIAL MEDICAL REPORTER.]

THE Oxford Meeting has proved a conspicuous success. Upwards of two thousand members and delegates have attended. Visitors came from all parts of the Empire, and many distinguished guests from afar. The weather, it is true, has damped much of the festive proceedings, but both gown and town extended an open-handed hospitality to the Association. The University threw open wide its doors, the President was indefatigable in the conduct of his onerous duties, local members of the profession were loyal and untiring, residents have assisted in many ways, the Press has admirably reported the proceedings, the scientific work of the sections has been good, the pathological museum excellent, and the exhibition of medical material thoroughly satisfactory. Altogether the gathering has proved of exceptional interest, and all concerned in the success of both professional proceedings and social functions may well be congratulated.

OXFORD—THE CITY AND UNIVERSITY.

This ancient seat of learning is truly a garden city of delight. Oxford is rich in all that makes for the joy of life. It offers unique attractions for all sorts and conditions of men. Countless objects of interest are ever at hand and the environment is one which peculiarly appeals to the student of human affairs. The University has offered all possible facilities to its medical visitors. The Examination Schools, the University Museum, and the Sheldonian Theatre have all been placed at the disposal of the Association. Many

of the Colleges with their chapels and halls and time-worn courts and venerable gardens, were thrown open. The Municipal Buildings have also been available. Every member of the Association was furnished with a copy of the special edition of Alden's admirable Oxford Guide, which, with its key-plan of the University and city proved invaluable to strangers.

#### SPECIAL ASSEMBLIES.

The official programme was from Tuesday, July 26th, to Friday, July 30th, but not a few visitors extended their visit by additions at both ends. A special service was held in Christ Church Cathedral on Tuesday morning, when the Master of University College, the Rev. J. Franck Bright, D.D., son of the famous Guy's Hospital physician, preached from St. John's Gospel v., 17, "My Father worketh hitherto and I work." A special Mass was also said at the Church of St. Aloysius. Religious services were held on Wednesday morning at Mansfield College Chapel and at Manchester College Chapel.

A large and brilliant gathering assembled in the Sheldonian Theatre on the evening of the 26th to hear the Presidential address and to witness the reception of distinguished guests. Dr. Collier delivered an appropriate and interesting address on "The Growth and Development of the Oxford Medical School."

On Wednesday, the 27th, the Conferment of honorary degrees attracted much interest. The degree of D.Sc. *honoris causa*, was conferred on Professor Clifford Allbutt, Mr. Andrew Clark, Dr. F. D. Griffiths, Mr. Jonathan Hutchinson, Sir William MacEwen, Sir Patrick Manson, Sir John William Moore, and Professor William Osler.

The Address in Medicine was delivered by Sir William Selby Church, who dealt with sanitation, particularly in reference to national health. The Address in Surgery was given by Sir William MacEwen, who treated of cerebral invasion by pathogenic and pyogenic organisms and other matters connected with surgical technique.

A desirable innovation was furnished in the popular lecture illustrated by some ninety lantern slides, given in the Town Hall on Thursday evening by Dr. G. Bagot Ferguson, who, in an attractive manner, presented the more important points relating to "disease germs" to the large and appreciative audience.

The annual medical temperance breakfast which this year received due recognition on the official programme of the Association, was held on Thursday morning in the Assembly Room of the Town Hall, and was largely attended. Mr. McAdam Eccles presided, and was supported by many influential members. The President of the Association spoke, and Dr. T. N. Kelynack gave an address on "The Medical Aspect of Alcoholism."

#### THE GENERAL AND REPRESENTATIVE MEETINGS.

Under the new *regime*, the purely business part of the Association is localised and concentrated, and its conduct, under the able chairmanship of Sir Victor Horsley, is greatly facilitated. The details of the work accomplished are duly published in the Official Journal, and much time and temper is saved by the new method of procedure, and we believe the usefulness and dignity of the Association is hardly likely to suffer by the incoming of the new dispensation. The question of medical defence gave rise to much discussion, and the matter is to be thoroughly investigated during the year. Hospital reform and contract practice also received consideration.

#### THE WORK OF THE SECTIONS.

The real scientific work of the meeting was conducted in fifteen separate sections, the majority of which found excellent quarters in the splendid and in every way convenient University Museum Buildings. The attendance was generally good. Much interest was taken in the various set discussions, which, although far from epoch making, were nevertheless usually helpful and suggestive and characterised by a sound practical directness. Many of the papers presented were of considerable value. The more important subjects dealt with we hope to summarise in our pages.

#### SECTION OF MEDICINE.

A discussion on the "Treatment of Chronic Interstitial Nephritis," introduced by Dr. W. Hale White, a full abstract of whose paper will be found in another column, aroused much interest. Albuminuria was considered of insignificant importance, but cardio-vascular conditions needed much management. Professor von Noordan advised the employment of well-regulated exercise, deprecated the excessive use of fluids, and would not withhold a meat diet. Professor Osler's opening paper to the discussion on "Tuberculous Pleurisy and Pneumothorax" admirably summarised the best modern views of dealing with these conditions. A discussion on the "Serum Treatment of Disease" was opened by Dr. E. Goodall. Many papers of value were presented, including those by Drs. Mackenzie and Nicholson, on the "Maternal Heart in Pregnancy," Dr. Gibson on "Bradycardia," and Mr. Hastings Gilford on "Ateleiosis." Some of the communications were illustrated by lantern slides. The attendance at this section was very good.

#### SECTION OF SURGERY.

The question of "Asepsis and Antisepsis," introduced by Mr. F. F. Burghard, afforded useful opportunity for the comparison of present day methods of surgical technique. The discussion on "Hysterectomy Retroperitoneal Tumours and Cervical Fibroids" attracted many gynaecologists. A number of papers were also presented.

#### SECTION OF OBSTETRICS AND GYNÆCOLOGY.

Sir Arthur Macan opened the first day's discussion on the "Treatment of Accidental Hæmorrhage." Dr. Herman and many others also contributed to the "Study of the So-Called Ovarian Pains." A number of papers of gynaecological interest were also presented.

#### SECTION OF STATE MEDICINE.

Here many matters concerned with personal and public hygiene were discussed. Dr. J. S. Haldane dealt with "Standards of Ventilation." "Poverty and Public Health" were ably presented by Mrs. Bosanquet, Mr. T. P. Whittaker, M.P., and Alderman Hugh Hall. The co-operation of laymen offers a procedure which merits much approbation.

#### SECTION OF PSYCHOLOGICAL MEDICINE.

Dr. Charles A. Mercier in his presidential address reviewed the subject of "Criminal Responsibility and Degeneracy." The discussion on "Heredity in its Biological and Psychiatric Aspects" gave rise to much of interest, and the contributions of Dr. J. Beard and Dr. W. König were listened to with much attention. Dr. Conolly Norman opened a discussion on "Dementia Præcox."

#### SECTION OF PATHOLOGY.

Dr. James Ritchie, the President of the Section, concisely presented the various views promulgated as to "Immunity," and several papers dealing with the subject were read. Professor von Noordan opened a discussion on the "Chemical Pathology of Gout," and Dr. Lovell Gulland and Professor Muir dealt with the "Physiological and Pathological role of the Lymphocyte."

#### SECTION OF OPHTHALMOLOGY.

The meetings of this section were held in Keble College. The President, Mr. Marcus Gunn, opened this discussion on "Retro-Ocular Neuritis." "Intra-Ocular Hæmorrhage and Systemic Disease," and "Keratitis Profunda," were also subjects which gave rise to considerable discussion.

#### SECTION OF LARYNGOLOGY AND OTOTOLOGY.

Dr. Urban Pritchard dealt with the ever interesting matter of the "Treatment of Non-Suppurative Diseases of the Middle Ear." The etiology, treatment, and prognosis of innocent growths of the larynx and intra-nasal disease as a determining factor in the production of laryngeal and pulmonary affections offered much fruitful matter for discussion. A considerable number of papers were also presented.

#### SECTION OF NAVY, ARMY AND AMBULANCE.

Many questions of Imperial interest were dealt with,

including the "Sanitation of Camps," "Malta Fever," "Mediterranean Fever," "The Medical Equipment and Transport for Volunteer Brigades."

#### SECTION OF TROPICAL DISEASES.

The more important subjects considered include "Trypanosomiasis," "The Prophylaxis of Malaria," and "The Significance of the Leishman-Donovan Bodies." A number of papers dealing with various tropical diseases were also read.

#### SECTIONS OF ANATOMY AND PHYSIOLOGY.

These sections appealed chiefly to teachers in our medical schools. Important discussion took place on the "Thalamic Region," "Chloroform Anæsthesia," and "Giants and Dwarfs."

#### SECTION OF DERMATOLOGY.

Discussion took place on Pruritus Ani; the Comparative value of old and new methods of treating lupus and other skin diseases, and the relative importance of the bacterial and other factors in the causation of skin diseases.

#### SECTION OF DENTAL SURGERY.

A discussion on oral sepsis attracted considerable interest, and numerous physicians and surgeons took part.

#### THE PATHOLOGICAL MUSEUM.

Special efforts had been made to secure a thoroughly representative collection which should illustrate the best results of recent investigations, and Dr. James Ritchie and Dr. E. W. Ainley Walker and their Committee may well be congratulated on the high standard of excellence attained. The carefully-prepared catalogue of 80 pages gave particulars of 1,028 exhibits. The Anatomical Department of the University Museum afforded admirable quarters, and the display of specimens and drawings allowed of ready and convenient inspection. The collection is undoubtedly the best for many years past, and it is to be regretted that it has to be dissipated so speedily.

The products of photography occupied much space. Many photo-micrographs were on view, and the results of colour photography attracted much attention. Stereoscopic work was well represented, and there was also a large collection of radiographs.

There were many excellent drawings illustrating dermatological and other clinical cases.

Among the numerous specimens special attention deserves to be called to the preparations illustrating the most recent work connected with the pathology of new growths; the causation of so-called "sleeping sickness," and various neurological studies.

The "pickles" were of considerable importance, especially the collection of preparations illustrating the morbid conditions affecting the vermiform appendix; the surgical treatment of gastro-intestinal lesions; and the pathology of the prostate.

Many specimens of exceptional importance were found in the section of obstetrics and gynaecology. The collection of preparations illustrating laryngology and otology was somewhat meagre. A feature of real value was that which dealt with apparatus and methods. The arrangement by which workers were enabled to actually describe and explain their methods in afternoon demonstrations is to be highly commended.

An excellent collection of ophthalmological specimens was open to inspection at Keble College.

The University Herbarium situated at the Botanic Gardens was also open to members.

#### THE EXHIBITION.

We can well imagine the horror which certain dons of the University would have experienced could they have seen their magnificent Examination Schools given over to the purposes of a trade show and invaded by meat extracts, infants' foods, mineral waters, and the like. This year's Exhibition, however, has been well arranged and extensively visited, its location in the same building as the reception room making it particularly convenient of access. The arrangements have been entirely in the hands of the headquarters staff, and, generally speaking, the arrangements were judicious.

The catalogue formed a bulky volume of 220 pages, and there were 116 exhibitors. Drugs and new

synthetic preparations were not so conspicuous as usual. Surgical instruments and appliances were present in great abundance. There was also a fair show of sanitary appliances. Foods and food products were extensively represented, and many exhibitors of mineral waters and beverages had been found a place. A few publishers of medical works had stalls, but some of the largest and most important houses were conspicuous by their absence.

We propose next week to deal with some of the more important exhibits.

#### THE ENTERTAINMENTS.

The purely festive features of the Oxford meeting have been notable. The unsettled nature of the weather added much to the perplexities of management, but throughout the arrangements for the comfort and enjoyment of the visitors were excellent. On Wednesday afternoon the President and members of the Oxford division gave a reception in the charming Wadham College gardens; and at the same time a duelling and fencing exhibition, with epee contest between Oxford and Cambridge, was held in the Town Hall. In the evening a largely attended soirée at the Museum was given by the Vice-Chancellor and members of the University, at which there were many attractive exhibits and scientific demonstrations.

On Thursday garden parties were given by Dr. and Mrs. Neil at the Warneford Asylum, and Mr. and Mrs. G. H. Morrell at Headington.

The annual dinner was held in the ancient and famous great hall of Christ Church; and on the same evening a particularly delightful reception was held by the Ladies' Committee in the New College Gardens and Hall.

On Friday the Duke of Marlborough gave a garden party at Blenheim Palace, and in the evening the Mayor of Oxford (Dr. E. A. Bevers) held a reception in the city buildings.

During the week promenade concerts were given in the gardens of St. John's College and Worcester College.

Many visitors availed themselves of numerous opportunities for river excursions, visits to the Clarendon Press, inspection of the various colleges and many other buildings of interest in Oxford.

Excellent arrangements were made for visitors. Many resided in the colleges. The Reception Room was well managed, and comfortable reading, writing, and smoking rooms were provided. Special rooms were available for ladies.

#### THE EXCURSIONS.

The picnic aspect of the meeting cannot be neglected. Many practitioners are obliged to make the yearly gathering an important part of their annual holiday, and it is well that the purely pleasurable side should not be allowed to suffer neglect.

On Saturday a large party visited Leamington, and later attended a garden party given by the Countess of Warwick. Others took part in a river excursion to Reading and Henley, while not a few continued their rambles about the quiet courts and quaint College precincts of this ancient seat of learning.

#### MISCELLANEOUS.

The Oxford Meeting has been characterised by a delightful combination of utility and festivity, professional industry and social enjoyment. The combination of ancient environment and modern methods has heightened the interest of the gathering. Even in the entertainments science has not been ousted. At the Vice-Chancellor's *Conversazione* many exhibits of high value attracted attention especially the performances of the mice bred by Mr. A. D. Darbishire, by crossing a race of Japanese "waltzing" mice with ordinary European albinos, and illustrating the failure of "Mendel's Laws."

The enterprising firm of Burroughs Wellcome and Company issued to members a dainty little pocket manual, "Oxford Medical Lore," which contained much information of historical interest.

Various important meetings were held during the week, and served to rally those members interested in the work of the New Sydenham Society, the Irish

Medical Schools' and Graduates' Association, the Continental Anglo-American Medical Society, and the United Kingdom Police Surgeons' Association.

Next year's meeting of the Association is to be held at Leicester, the President-Elect being Mr. George Cooper Franklin, F.R.C.S., Surgeon to the Leicester Infirmary.

### Obituary.

HUGH WILLIAMS, L.R.C.S. & P.ED., LIVERPOOL.

THE death took place on the 26th ult., at his residence in Liverpool, of Mr. Hugh Williams, one of the best-known men in Everton. Deceased, who was 59 years of age, had spent practically all his life in this city, and for many years carried on a large practice. He was extremely popular among the poor, to whom he always showed a generous disposition. Although taking no prominent part in public affairs, the deceased was keenly alive to all that was taking place around him. Some time ago Dr. Williams proceeded to Egypt for the benefit of his health, which showed signs of breaking up. He did not, however, overcome the disease from which he was suffering. Deceased leaves a widow and several children. His professional education was conducted at the Liverpool Medical School. In 1878 he qualified as Licentiate of the Royal Colleges of Physicians and Surgeons at Edinburgh.

FREDERICK FLINT, M.D.ABER., M.R.C.S.ENG. SCARBOROUGH.

We regret to announce the death, on the 25th ult., at Kirbymoorside, of Dr. Frederick Flint, of Scarborough. Dr. Flint had been ailing for some time past, and on the advice of Sir Thomas Barlow took up his residence at Kirbymoorside some three weeks ago. The deceased gentleman, who was in large practice at Scarborough, was 62 years of age, and leaves a widow, three sons and six daughters. He had practised in Scarborough for the past thirty years—during the last seventeen years of that period in conjunction with Dr. Ross. For a number of years he was senior deacon at Bar Congregational Church. He has left a wide circle of friends to mourn his loss. Dr. Flint was educated at King's College, London, whence he took the M.R.C.S.Eng. in 1866. In 1870, he graduated M.D. at Aberdeen University.

JOHN JOSEPH CRANNY, M.A., M.D., F.R.C.S.I.

WE regret to announce the death of Dr. John Joseph Cranny, of 17, Merrion Square, on the 27th of July, at the age of 59. He was one of the best known and most popular as well as the most scientific medical men in Dublin. Apart from his professional reputation, he was widely known as a benevolent and philanthropic man, although of so modest a disposition that the origin of many of his benefactions remained unknown. He took his B.A. degree in the University of Dublin in 1869, together with the degree of Bachelor of Medicine. He then practised at the Rotunda Hospital; took his Fellowship at the Royal College of Surgeons in 1870, and his degree of medical doctor in Trinity College in 1872. Since that time he had been amongst the leaders of his profession in Dublin. He was one of the surgeons attached to Jervis Street Hospital, an Examiner in Midwifery of the College of Surgeons, an Assistant Physician of the Rotunda Hospital, a Fellow of the Royal Academy of Medicine, a member of the British Medical Association, of the Royal Dublin Society, and the Royal Irish Academy. His culture however, was of a versatile type that extended far beyond the confines of his own profession. Among his contributions to medical literature may be mentioned "On Polypus of Uterus and use of Sea Tangle Tents," and "Obstruction of Bowels successfully treated by Laparotomy," published in the *Dublin Journal of Medical Science* in 1889.

D. F. B. REARDON, L.R.C.P.I. AND L.M., OF BRUFF.

WITH much regret we announce the death of Dr. D. F. B. Reardon, of the Hermitage, Bruff, which

took place, after a short illness, at the Whitworth Hospital, Dublin, at the early age of 45 years, and in the 22nd year of a distinguished medical career. His early and unexpected demise has caused intense grief to his afflicted family as well as to a large circle of friends. Dr. Reardon had endeared himself to all who knew him by his straightforward principles, kindness, and sympathetic disposition, especially towards the poor, who have every reason to mourn his loss. He was a long standing subscriber and supporter of THE MEDICAL PRESS AND CIRCULAR. His medical education was conducted at the Royal College of Surgeons, and Ledwick School, Dublin, whence in 1880 he took the qualification of L.R.C.S.I.

### Literature.

THE TRYPANOSOMIASIS EXPEDITION TO SENEGAMBIA. (a)

THIS monograph is a credit alike to English scientific work in general, to the Liverpool School of Tropical Medicine in particular, as well as to Drs. Dutton and Todd, its authors. The stay-at-home reviewer, whose opportunities for observing trypanosomiasis are a negligible quantity, may be pardoned if, unlike arm-chair strategists, he abstains from criticism of a piece of work bristling with new and interesting facts, and tries merely to give a brief general summary of the author's results. Trypanosomes, then, were found in man, horses, rats, mice, tortoises, snakes, and frogs; this report contains a great deal (and the promise of more) about the first two of these forms, and a shorter account of the others. Section I. deals with laboratory methods, and here we must thank the authors for having taken the trouble to define the meanings of the various names of leucocytes used in their differential counts, for almost nothing (and we speak from a not inconsiderable experience of the literature of blood diseases) is a greater source of confusion than the vague way in which the terms "lymphocyte" and "mononuclear leucocyte" are used by different writers; this the authors have realised, and their work is in consequence the freer from ambiguity. Section II. deals with the human trypanosome, which was found in six out of 1,043 natives examined (a number probably below the real frequency). No evidence was found that infection was favoured by any particular type of locality. A clinical description of two European and six native cases is given, from which it would seem that the disease is so mild as readily to escape notice. Besides the parasite, the blood shows eosinophilia and increase of mast-cells and mononuclears, the last containing deep lake-coloured granules when stained by a modification of Romanowsky's method. In Section III. the equine form of the disease is described, the horse being the only animal in which a pathogenic trypanosome has been found; it was found in ten out of thirty-six animals. The disease is chronic, occurs generally throughout the Colony, and is possibly more prevalent near the river, especially in the rainy season. The morphology of the human and equine trypanosome is described in Section IV, and in Section V. are given the details of a series of attempts to transmit the disease to rats and mice by tsetse-flies. In this the authors were unsuccessful, possibly because the excessive lack of moisture in the air (in the dry season) prevented the trypanosomes from living on the proboscis of the tsetse-fly. From the results of inoculation of mice and rats the writers believe that human and equine trypanosomiasis are different diseases. The last section gives a description of the species of flagellata met with in other animals. The report is fully illustrated with maps, charts, photographs and coloured plates, for all of which, especially the last, the publishers deserve much praise. A second report, treating of the more purely pathological aspects of trypanosomiasis, is promised.

(a) "First Report of the Trypanosomiasis Expedition to Senegambia (1902)." By J. Everett Dutton, M.B., and John L. Todd, M.D., Liverpool School of Tropical Medicine. Memoir XI. London: Longmans, Green and Co. 1903. 4to, pp. 57.

## THOMSON'S MANUAL OF SURGERY (a)

IN the preparation of this work, the authors, as stated in the preface, have endeavoured to furnish a systematic view of the present-day aspects of surgery in sufficient detail to render it useful to the practitioner, without at the same time carrying it beyond the scope appropriate to a manual for students. They have curtailed as far as possible theoretical and debatable matter, and have only described pathological processes in so far as they bear directly on diagnosis and treatment.

Chapter II., dealing with conditions which interfere with repair, gives some very instructive temperature charts illustrating the various ways surgical cases "go wrong." In the treatment of burns the authors find the application of a watery solution of picric acid most satisfactory, it yields the best results in the more superficial burns, but is useful as a primary dressing in all. The treatment recommended for shock does not correspond with recent work on the subject, for strychnine is recommended as the best of all.

The chapters devoted to the injuries of bones and joints are very good. With regard to fractures of the internal condyle of the humerus, the authors say: "It is sometimes necessary to fix the small fragment in position by a nail inserted through the skin." This seems to us to be a barbarous method of treating such an injury, for the risks are equal to those of an open operation without the advantages of the latter. A similar procedure is recommended in some cases of T-shaped fracture of the same bone, and in fractures through the neck of the femur. We are glad to see Bennett's fracture of the base of the first metacarpal bone fully described and illustrated, although a fairly common injury, it is frequently omitted in surgical works.

We should like to see the following statement omitted:—"The best method of treating a fracture of the patella is still *sub judice*," as undoubtedly operative measures give the best results in all cases in which there is any displacement of the fragments. A simple method of ambulatory treatment is given for fractures in the region of the ankle-joint, which should be of great use in hospital cases. In the treatment of tuberculous joints the authors speak highly of injections of iodoform and the artificial production of venous congestion.

The volume, which concludes with an excellent chapter on "Deformities of the Extremities," is illustrated with wood cuts, the majority of which are exceedingly good. We must congratulate the authors on the way they have begun their task, and we await with pleasure the second volume. We can strongly recommend the first to practitioners and senior students.

## AILMENTS OF WOMEN AND GIRLS. (b)

IN this volume the authoress again enters the medicoliterary field bearing the excelsior standard of the physical improvement of her sex. We think it is well to hear a woman's voice sometimes, in the description of conditions and sensations regarding which her evidence is first-hand, while that of man can never reach beyond the "hearsay" stage. There is but too much sad truth in the quotation given in the opening sentence of the preface: "The past generations of women were taught to suffer in silence. . ."; but it is consoling to be told by the same author that "suffering is not woman's necessary lot." The present volume is apparently the outcome of a laudable desire to contribute to the diminution of this suffering. The merit of such aim cannot be called in question. Of course, the enormous scope included prevents the thorough treatment of any of the subjects dealt with;

(a) "Manual of Surgery." By Alexis Thomson, M.D., F.R.C.S. Ed., Assistant Surgeon Edinburgh Royal Infirmary; Surgeon to the Deaconess Hospital, Edinburgh; and Alexander Miles, M.D., F.R.C.S. Ed., Assistant Surgeon Edinburgh Royal Infirmary; Surgeon to Leith Hospital. Volume I.—General Surgery. With 262 wood engravings. Pp. 763 and xvii. Edinburgh and London: Young J. Pentland, 1904.

(b) "Ailments of Women and Girls." By Florence Staepoole, Lecturer for the National Health Society, &c. Bristol: John Wright and Co. 1904. Price, cloth, 3s. net.

but the authoress, judiciously and philanthropically, gives "a serious warning as to the danger incurred by women attempting to treat themselves in any way beyond the moderate limits here laid down." There is a great deal of excellent information and advice given with regard to menstruation and its disorders, which should certainly prove valuable to most female readers, but especially to those of the rising generation. The volume before us is well written, and within the limits imposed by the authoress herself, we cordially recommend it to both mothers and daughters.

## LEFTWICH'S INDEX OF SYMPTOMS. (a)

THIS is the third edition of a useful little book for use on the consulting room table. The rapid sale of a former edition proves that the author's book fills a genuine gap in medical literature. The attempt to systematise so complex a subject could never be completely successful. At the same time much can be done to lighten the pathway of diagnosis, which often lies in deep shadow. The author has wisely drawn attention by means of an asterisk to the more probable diseases, out of the many that often follow a single symptom. An interesting illustration of the multiple significance of a single symptom may be taken in "headache," which may arise from any one of a formidable list of causes. Dr. Leftwich has added a variety of useful and accurate information to the main motive of his book.

WE have received from the Scientific Press another contribution to the evergreen subject of "Medical Tuberculosis: Its Natural Cure," written by R. B. Searle, L.R.C.P., M.R.C.S., L.S.A., Mayor of Dartmouth. The most charitable remark we can make concerning this venture is that it is an amusing little monograph, which can hardly be considered a serious contribution to the literature of progressive medicine. Mr. Searle writes with the enthusiasm and dogmatism of the unscientific faddist, and offers no reliable evidence for the remarkable conclusions at which he arrives. He would treat tuberculosis by the introduction of the typhoid bacilli, and their toxins, a procedure which we believe cannot be supported as justifiable by either experience or experiment. Much of the pathology in this pamphlet is bizarre, as, for instance, the declaration that cancer "may be looked upon as a malignant variety of tuberculosis." We think the author has been ill-advised in publishing his views in such a form. His manner and method of presentation are not likely to further scientific medicine. We are of the opinion that such a work as this is likely to produce incalculable harm should it fall into the hands of ignorant and suffering laymen.

\*\*\*

THE "Edinburgh Stereoscopic Atlas of Anatomy," by David Waterston, M.D., Lecturer and Senior Demonstrator in Anatomy in the University of Edinburgh, marks a new departure in the teaching of that subject. By means of photographs viewed stereoscopically a most lifelike picture is given of dissections of the chief parts of the body. It is needless to remark that nothing can ever take the place of actual dissecting, but at the same time it is impossible to dissect away from the medical school. The student or the practitioner by reference to the stereoscopic atlas can at any time refresh his mind by means of a valuable objective reproduction. The idea is an excellent one, and the Atlas is likely to score a big success. It is to be produced in a series of 250 stereographs at £6 5s. net. The publishers are Messrs. T. C. and E. C. Jack, of Edinburgh.

\*\*\*

"THE Livingstone College Year-Book for 1904" (Leyton: Livingstone College), in addition to particulars concerning the aims and objects of the institution and report as to its recent work, contains a series of hints for the preservation of health in the

(c) "An Index of Symptoms." By R. Winnington Leftwich, M.D., late Assistant Physician East London Children's Hospital. Third edition. Smith, Elder and Co. London: Price 6s. net. 1904.

tropics which will be of suggestive value to medical men and others interested in the selection and examination of missionaries and those who are called upon to live in tropical regions.

### NEW TABLOID PREPARATIONS.

MESSRS. BURROUGHS WELLCOME AND Co. have brought out a "tabloid" of calomel and opium. Each disc contains Calomel, gr. 1; powdered opium, gr.  $\frac{1}{4}$ . "Tabloid" calomel and opium will be found a good means of securing the combined action of the two drugs. Each product is prepared with pure drugs presented in a condition to disintegrate quickly after administration and promptly produce the therapeutic effect. This preparation is likely to be appreciated, in view of the well-known tendency of calomel pills to become hard.

ETHYL-MORPHINE hydrochloride, issued under the name of Dionin, is said to have been recently submitted to clinical trial with satisfactory results. From the published reports this agent appears to possess definite analgesic properties, and at the same time to be free from the disadvantages so often associated with the employment of morphine and its salts. No instance of euphoria or euphoric symptoms following the use of Dionin has been recorded. It possesses the further advantage of being, with the single exception of codeine phosphate, the most soluble of the morphine derivatives. The properties of Dionin render it specially useful in ophthalmic work. It is used in iritis, keratitis, glaucoma, vitreous opacities, corneal opacities, and sympathetic ophthalmia; but is contra-indicated in arterial sclerosis of the aged.

THERE is no need to remind medical readers that combinations of sodium bicarbonate with calomel and with grey powder respectively are usually prescribed in the form of powders. There are, however, certain disadvantages associated with the administration of medicines in that form. Messrs. Burroughs Wellcome and Co. have now introduced these useful remedies in "tabloid" form, so that in future medical men will be assured that their patients will obtain full and accurate doses of absolutely trustworthy drugs. The two new tabloids are "tabloid" calomel and sodium bicarbonate, and "tabloid" grey powder and sodium bicarbonate, made up in varying doses.

ANOTHER "tabloid" issued by the same firm is that of the three valerianates—Quinine valerianate, gr. 1 (0.065 gm.); iron valerianate, gr. 1 (0.065 gm.); zinc valerianate, gr. 1 (0.065 gm.). A combination highly praised in some quarters as an efficient tonic. Still another "tabloid" is the valerianate of zinc in combination with 1-60th gr. of arsenious acid and 1 gr. of reduced iron.

## Medical News.

### Therapeutical Society.

AN informal meeting of this society was held in the gardens of the Royal Botanic Society, Regent's Park, by permission of the secretary, J. Bryant Sowerby, Esq. Dr. F. de Havilland Hall was in the chair, and fifteen Fellows attended the meeting. Dr. Brown, the secretary of the Therapeutical Society, showed specimens of the seeds of the Sapota cedron, sent by J. H. Hart, F.L.S., from Trinidad, and some Chinese medicinal roots from Miss Florence Cooper, of Lo'nguog City, Fouchow, China, both persons being corresponding Fellows of the Therapeutical Society. Mr. Bryant Sowerby showed various specimens of medicinal plants and drugs, and also a very fine plant of the Victoria Regia in full bloom, and numerous other medicinal plants and trees growing in the garden. The Fellows present afterwards had tea in the club in the gardens.

### The Cholera in Persia.

A REUTER'S telegram states:—"The *Transcaspian Review* states that the cholera at Teheran has lost its menacing character. The mortality has decreased from 1,500 deaths daily to 300. There is panic only among the natives, who, in consequence of the enor-

mous rise in the prices of provisions, have fled into the country. The measures taken by M. Grube, the Russian Financial Agent, with the assistance of the Russian Legation, have averted disturbances. By the flight of the inhabitants the cholera has been carried into the surrounding country, and it is now raging in the villages. When these people return to the city there is a possibility of the epidemic, as in 1892, again assuming a dangerous character."

### Action for Malpractice.

AN action was heard at Belfast on July 21st and 22nd, before Mr. Justice Wright, in which Mr. Alfred Ernest Inghan, a minor, sought to recover £250, on account of personal injuries alleged to be due to the negligence of Dr. C. K. Darnell, of Bangor the defendant. The alleged negligence was in the prescription of belladonna liniment, as a result of which it was said the plaintiff's life became in danger, and he suffered extreme pain, becoming delirious for some time. Defendant denied negligence on his part, and stated that any injuries that had occurred were solely caused by the negligence of the plaintiff's friends. Several expert witnesses were examined, and the jury, after considerable deliberation, disagreed, and were discharged.

### The London Hospital Medical College.

THE following distribution of prizes was made last week to the successful students during the session 1903-1904. "Price" scholarship in science, £120, Mr. W. H. Palmer; "Price" scholarship in anatomy and physiology, £60, H. S. Souttar; entrance science scholarship, £60, J. E. Scudamore; entrance science scholarship, £35, J. P. Johnson; "Buxton" scholarship, arts, £30, J. G. Watson; "Buxton" scholarship, arts, £20, G. S. Candy; Epsom scholarship for students of Epsom College, D. G. Evans; clinical medicine, £20 scholarship, J. Lambert; clinical surgery, £20 scholarship, E. Ward and J. Lambert; clinical obstetrics £20 scholarship, A. J. Walton; "Andrew Clark" prize, £26 (biennial), A. J. Walton; "Letheby" prize, senior, £20, G. S. Candy; "Letheby" prize, junior, £10, F. Hitch; "Sutton" scholarship, £20, A. J. Walton; anatomy and physiology, £25, R. C. Roberts; anatomy and biology, £20, J. P. Johnson. Together with several minor prizes and hon. certificates.

### The Prevention and Treatment of Cancer.

IN view of the increasing prevalence of cancer, the Committee of the Liverpool Cancer Research deem it their duty to call attention to what may be done to combat this increase. No specific cure for cancer is yet known, but, as with consumption, the earlier the treatment is commenced the greater is the chance for its success. Unfortunately, a large number of people put off seeking the advice of their doctor instead of going to him immediately they notice anything wrong. It may be pointed out that certain organs are more often affected than others. In men, cancer of the gullet, stomach, and intestines; in women, cancer of the breast and the womb, account for about two-thirds of all cases of cancer. There are, of course, many other only slight ailments of these organs. The Committee feel that they cannot too strongly state how important it is that the disease should be recognized at the earliest possible moment. This recognition can only be attained by the patient going to his or her doctor for examination at the very beginning of illness.

### The Royal University of Ireland.

THE Senate met on Thursday, July 28th, the Right Rev. Monsignor Molloy, D.D., D.Sc., Vice-Chancellor of the University, in the chair. The secretaries reported the deaths of the following members of the Senate:—William A. McKeown, M.D., on July 9th, and Edmund Dease, M.A., on July 17th. The following resolution was proposed by Sir Christopher Nixon, seconded by Rev. Dr. N. McA. Brown, and passed unanimously:—"The Senate desires to record its deep regret at the death of William Alexander McKeown, M.D., and to express its high appreciation of the zeal and energy with which he devoted himself to the interests of the University, especially to those

of the Medical Faculty, from the time of his appointment as Senator at the foundation of the University."

The following resolution was proposed by His Honour Judge Shaw, seconded by His Grace the Most Rev. Dr. Healy, Archbishop of Tuam, and passed unanimously:—"The Senate desires to record its deep regret at the death of Edmund Dease, M.A., who has been a member of the Senate since the foundation of this University; and to express its sense of the benefits which the University derived from the wide experience of public affairs, the high sense of duty, the unswerving integrity, and the unflinching courtesy which Mr. Dease brought to the deliberations of the Senate."

#### Irish Medical Schools' and Graduates' Association.

THE summer general meeting of the above Association was held on Wednesday, July 27th, at the University Museum, Oxford, the President, Surgeon-General Sibthorpe, C.B., in the chair. Among those present were Sir Charles A. Cameron, C.B. (Dublin); Lieut.-Colonel Boileau, M.D., A.M.S. (Trowbridge); Dr. James Little (Dublin); Dr. Percy V. Dodd (Folkestone); Dr. William Douglas (Goudhurst); Dr. Robert Esler; Dr. T. Gelston Atkins (Cork); and the provincial hon. secretary, Dr. James Stewart (Clifton). The following resolution, proposed by Dr. Atkins, and seconded by Sir Charles Cameron, was passed unanimously:—"That a copy of the two resolutions adopted at the Special General meeting of May 25th be sent to the Chairmen of the various Boards of Guardians throughout Ireland, together with any additional statements the Council may think fit to forward, with a view to strengthening the case of the Irish Poor-Law medical officers." The meeting then adjourned.

#### University of London.

THE following candidates have passed the M.D. examination:—Hugh Barber, Helen Beatrice Hanson, Arthur Charles Haslam, Septimus M. Hebblethwaite, Norris A. Houghton, Colin Dunrod Lindsay, John Ford Northcott, Claude Rundle, Richard Hamilton Townend. William Ferris, B.S., passed in Mental Diseases and Psychology. The following have passed in Midwifery and Diseases of Women:—James Cole Marshall, Richard Maxwell, Thomas M. Pearce, George S. Robertson. Myer Coplans passed in State Medicine. The following have passed the M.S. Examination:—William Henry Bowen, David Leighton Davies, M.D., Walter Fedde Fedden, Sydney Richard Scott, Robert Gordon Strange.

#### Royal Colleges of Physicians and Surgeons of Edinburgh, and Faculty of Physicians and Surgeons of Glasgow.

At the July sitting of the Scottish Conjoint Board, held in Glasgow, the following candidates passed the respective examinations:—

*First Examination five years' course*—Alexander M'Murray, Belfast; John M'Kelvey, Belfast; Ernest Gibson, Cork; William G. Forde, Cloyne; Henry W. Turner, Glasgow; Osmonde R. Belcher, Cork; Thomas B. Ferguson, Kirkmaiden; Frank H. A. Riddle, Madras; Patrick J. Taaffe, Liverpool; John G. Buchanan, Tیره; David Welsh, Wilsontown; Karl F. Gover, Demerara.

*First Examination four years' course*—George V. Edwardes, Keatley.

*Second Examination five years' course*—John R. D. Holtby, Belfast (with distinction); John A. Smith, Glasgow; Fred. G. Allan, Whaley Bridge; John M. Muir, Kilmarnock; Joseph H. Patterson, North Berwick.

*Third Examination*—Alexander Brown, Galston; Percival Henderson, Skelmersdale; John Macnamara, Leitrim; John M'Arthur Falderbank; John M. Moriarty, Kerry; William F. H. Ives, London; Henry E. Bolton, Dublin; Joseph B. N. Raphael-Tom, Trinidad; John H. R. Bodedern, Anglesea.

*Final Examination* (and admitted licentiates of the three co-operating authorities):—James B. Patterson, Carlisle; Archibald F. G. Spinks, Southport; Robert Crothers, Banbridge; Thomas G. Campbell, Glasgow; William A. Magill, Belfast; George H. Waugh, Belfast; Llewellyn C. Nash, New Sheldon; Percy J. Thomson,

L.D.S., Glasgow; Thomas A. Fall, Partick; Henry E. Strathy, Pitlochry; Reginald W. Towney, Oswaldtwistle; Mathias A. L. dos Santes Vaz; John H. Fyfe, L.D.S.; Laurence Gavin, and David Haig.

#### Royal Colleges of Physicians and Surgeons in Ireland.

*Third Examination*.—Candidates have passed this examination as understated—Passed in all subjects—T. A. Burke, M. Cohen, E. G. Condon, P. F. Foran, W. Glennon, C. W. Greene, W. P. Kelly, T. H. Massey, M. O'Connor, J. R. Tobin, and C. H. Wilson.

*Completed Examination*.—R. Calnan, C. J. R. Clarke, S. C. Clarke, T. W. Conway, J. Corboy, J. B. Dwyer, T. J. Golding, P. E. Hayden, R. F. Hayes, H. Hosty, A. E. S. Irvine, L. F. Kelly, M. J. C. Kennedy, F. G. M'Caughy, T. J. Madden, R. V. Murphy, J. O'Donnell, W. D. Sammon, P. D. Sullivan, W. G. Wright.

*First Examination in all subjects*.—P. J. Timoney.

#### University of Birmingham.

THE following candidates have passed in the Faculty of Medicine:—

*Degree of Doctor of Medicine*.—(a) Official: John Douglas Stanley; (b) Under Ordinary Regulations: Jordan Lloyd.

*Degree of Master of Surgery*.—Official: John Thomas Hewetson and Thomas Wilson.

*Degrees of Bachelor of Medicine and Bachelor of Surgery*.—(a) Associate: Alex. Wathen Nuthall. (b) Past students of Birmingham Medical School; Tom William Beazeley, Charles York Flewitt, Sidney Cameron Lawrence, and William Arthur Loxton. (c) Under Ordinary Regulations; Alfred Ernest Remmett Weaver (scholarship), William Cook, Cuthbert Keay Gettings, and Leonard George Joseph Mackey.

*Degree of Bachelor of Dental Surgery*.—Henry Percy Pickerill.

*Diploma in Public Health*.—Parts I. and II. Thomas Dawson.

#### Conjoint Examinations in Ireland—Final Examination.

CANDIDATES have passed this examination as undernoted:—

*With Honours*.—James S. Sheill.

*Passed in All*.—Miss Alice M. Barry, Mathew Campbell, William I. Cowell, Michael Keane, William F. B. Loughnan, William L. Murphy, Arthur Lanigan O'Keefe.

*Completed*.—Andrew J. Bracken, George P. A. Bracken, Alfred N. Crawford, Christopher A. Cusack, Benjamin D. Gibson, George A. D. Harvey, Patrick Kinsella, Francis J. Lennan, William J. O'Sullivan, James Parker, and Thomas J. Ryan.

THE President of the Royal College of Physicians of Edinburgh, Dr. T. S. Clouston, recently announced the postponement of the consideration of a suitable dress for licentiates of the College. It is somewhat difficult to understand why this subject should be so persistently shelved by the authorities of that body. The recently formed association of Scotch diplomates has urged the Scottish Colleges to take some steps in this easily-arranged matter, and offered further to submit the design of a dress for approval. The Colleges declined that offer, but have not produced their own pattern. Licentiates and Fellows, however, will doubtless get that and other things, if they wait—and organise. The Hon. Sec. of the Scottish Diplomates' Society is Mr. Heather Bigg, Harley Street, London, W.

H.M. THE KING has appointed Sir William MacGregor, M.D., K.C.M.G., C.B. (Governor of Lagos), to be Governor and Commander-in-Chief of the Island of Newfoundland and its Dependencies.

UNDER the will of Mr. Henry Evans, banker, of Highfields, Derby, who died suddenly last week, the Derbyshire Royal Infirmary receives ten thousand pounds for the equipment of a permanent ophthalmic department.

DR. URBAN PRITCHARD delivered his valedictory address at Bordeaux, on Monday last, at the international Congress on Otology, at which Dr. Moure was unanimously elected President. All the countries of Europe and the United States of America were represented.

## Notices to Correspondents, Short Letters, &c.

**✎** CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive Signature or Initial*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

ORIGINAL ARTICLES or LETTERS intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

### THE HUMANE SLAUGHTERING OF ANIMALS.

THE recently published report of the Committee appointed to consider the Humane Slaughtering of Animals has pronounced emphatically in favour of public as against private slaughter-houses. (1) "In the interests not only of humanity," it says "but of sanitation, order and ultimate economy. It is highly desirable that, where circumstances permit, private slaughter-houses should be replaced by public abattoirs, and that no killing should be permitted except in the latter, under official supervision. (2.) The Committee no less emphatically condemns the Jewish system of slaughtering as at present practised, and reports that "until some method is devised, and adopted, for rendering the animals unconscious, previous to the 'casing' and throat-cutting operations, the Jewish system of slaughtering cattle should not be permitted in any establishments under Government control."

**PHARMACIST (Newcastle).**—Yes—a remarkably good action has been claimed for large doses of digitalis (4 grms. daily of the infusion) in the treatment of pneumonia. The introducer of this method, Braggadonia attributes the good effect to the antitoxic action exerted by digitalis against the metabolic products of Fraenkel's bacillus. The method deserves a trial.

**STUDENT.**—Yellow fever can be conveyed across the sea by ships that have no disease on board. It is distributed from person to person by a species of mosquito (*Styomyia Fasciata*), which harbours in water tanks and damp places. See an excellent note on the subject in the recently published Annual Report for 1903 of the Medical Officers of Health of the Bristol Port Sanitary District.

**R. M. BENNETT.**—If when an assistant you signed an agreement not to practise within a radius of four miles of your principal's residence you are practically excluded from practice in London. A clause of the kind under such circumstances is most unfair, and no assistant should be asked to put his name to anything of the sort.

A VERY distinguished doctor (writes a correspondent) tells the *Daily News* that the medical profession appears to be undermined only because of the difficulty at this time of the year in finding "loci tenentes." What a pity! Is this turning about of familiar Latin phrases, as the lady proved who talked of "omnibi," or as that other showed us who talked of "a state of doubtful ebriety"? Let us hope that the medical profession will not long have to deplore the want of "loci tenentes," or someone is sure to remind us very soon of what we seem to have heard before, that the medical profession used to be a very different thing. As the brilliant Fellow of All Souls remarked when deploring the decline of intellect in the younger Fellows, "D— it. We use to be *sus generis*."—*Manchester Guardian*.

**J. FRAUVAL (London).**—We do not know of any book dealing with the subject you mention. The general opinion of the medical profession is undoubtedly unfavourable to consanguineous marriages. It is impossible to approve of first-cousin marriages from the point of view of the interests of offspring.

## Vacancies.

- Ayr District Asylum.**—Junior Medical Officer. Salary £120 per annum, with board, furnished apartments, attendance, and washing. Applications to the Medical Superintendent.
- Brighton Throat and Ear Hospital** Church Street, Queen's Road.—Non-resident House Surgeon. Salary £75 per annum. Applications to Secretary, Mr. E. W. Pilbeam, 10 Black Lion Street, Brighton.
- House Surgeon**, for a small Hospital in the Midlands. Salary £100 per annum and board. Applications to Mr. P. W. Walker, 18 Waterloo Street, Birmingham.
- Humberstone Asylum, Leicester.**—Assistant Medical Officer. Salary £200 per annum, with furnished quarters and board. Applications to Medical Superintendent.
- Ingham Infirmary and South Shields and Westhoe Dispensary.**—Junior House Surgeon. Salary £75 per annum and residence, board and washing. Applications to James R. Wheldon, Secret-74 King Street, South Shields.
- Kent County Lunatic Asylum, Barming Heath, near Maidstone.**—Chief Medical Officer and Superintendent. Salary £800 per annum, with unfurnished house, coal, gas, milk, garden produce and washing for self and family. Applications to Francis R. Howlett, Clerk, to the Sub-Committee, 9 King Street, Maidstone.
- Mount Vernon Hospital for Consumption and Diseases of the Chest, Hampstead and Northwood.**—Resident Medical Officer. Salary £80 per annum, with board and residence. Applications, to William J. Morton, Secretary 7 Fitzroy Square, W.
- Mount Vernon Hospital for Consumption and Diseases of the Chest, Hampstead and Northwood.**—Honorary Dental Surgeon. Applications to William J. Morton, Secretary, 7 Fitzroy Square, W.
- North Cambridgeshire Hospital, Wisbech.**—Resident Medical Officer. Salary £100 per annum, with furnished rooms, attendance, coals, gas, and washing. Applications to William F. Bray, Secretary.
- Rotherham Hospital and Dispensary.**—Senior House Surgeon. Salary £110 per annum, with rooms, commons, and washing. Applications immediately to the Secretary, C. S. Baylis, 19 Moorgate Street, Rotherham.

The Aberaman and District Workmen Doctors Fund Committee.—Qualified Gentleman to take charge of a large Colliery District Practice. Salary £400 per annum, with free house, coal, assistants, dispenser, drugs, &c. Applications to Secretary.

## Appointments.

- COOPER, WILLIAM P., L.R.C.P. & S. Edin.,** House Surgeon to the Royal Westminster Ophthalmic Hospital.
- DALLY, J. F. HALLS, M.A., M.B., B.C. Cantab., M.R.C.S., Eng., L.R.C.P. Lond.,** Senior Resident Medical Officer to the Royal National Hospital for Consumption and Diseases of the Chest, Ventnor, I. W.
- DENT, CLINTON T., F.R.C.S. Eng.,** Chief Surgeon to the Metropolitan Police.
- DONALD, C. W., M.D., F.R.C.S.E.,** Surgeon to Cumberland and Westmoreland County Constabulary.
- DUPOUT, J. M., M.B., Ch.B. Edin.,** Assistant Resident Medical Officer to the Royal National Hospital for Consumption and Diseases of the Chest, Ventnor, I. W.
- NICHOLSON, HARRY OLIPHANT, M.D. Aberd., F.R.C.P. Edin.,** Assistant Physician to the Royal Maternity and Simpson Memorial Hospital, Edinburgh.

## Births.

- COOKE.**—On July 26th, at Church Square, Haddenham, Bucks, the wife of Frederick A. Cooke, M.D., M.R.C.S., L.R.C.P., of a son.
- FINLAY.**—On July 28th, at No. 10 Clarendon Road, Eccles, Lancs, the wife of G. L. K. Finlay, B.A., M.B., C.M., of a daughter.
- HARPER.**—On July 27th, at 7 Chiawick Place, Eastbourne, the wife, Alexander Harper, M.D., of a daughter.
- HARVEY.**—On July 21st, 1904, at 7 Gardiner's Row, Rutland Square, Dublin, the wife of E. J. Harvey, F.R.C.S.I., of a son.

## Marriages.

- WACHER—PEEBLES.**—On July 28th, at St. Alban's Church, Windesham, Harold Wacher, M.B., eldest son of Frank Wacher, of Monastery House, Canterbury, to Violet Amy, daughter of the late Robert Davie Peebles, of the Priory, Heene, Worthing, and of Mrs. Peebles, of Fosters, Windesham.
- WHITTINGHAM—DUKES.**—On July 27th, at St. Michael's, Bournemouth, Edwin Parton, eldest son of Edwin Whittingham, of Bournemouth, to Amy Barbara, only daughter of the late W. P. Dukes, M.R.C.S., of Spitalfields, and Mrs. Dukes, of Christchurch.

## Deaths.

- CRANNY.**—On July 27, at 17 Merrion Square, Dublin, John Joseph Cranny, M.D., F.R.C.S.I., eldest son of the late Patrick Cranny, of Muckross Park, aged 69 years.
- CROCKER.**—On July 18th, at West Malling, Kent, Henry Leonard, fourth son of the late Surgeon-General Alfred Crocker, Army Medical Department.

## OPERATIONS.—METROPOLITAN HOSPITALS.

- WEDNESDAY.**—St. Bartholomew's (1.30 p.m.), University College (2 p.m.), Royal Free (2 p.m.), Middlesex (1.30 p.m.), Charing Cross (3 p.m.), St. Thomas's (2 p.m.), London (2 p.m.), King's College (2 p.m.), St. George's (Ophthalmic, 1 p.m.), St. Mary's (2 p.m.), National Orthopaedic (10 a.m.), St. Peter's (2 p.m.), Samaritan (9.30 a.m. and 2.30 p.m.), Gt. Ormond Street (9.30 a.m.), Gt. Northern Central (2.30 p.m.), Westminster (2 p.m.), Metropolitan (2.30 p.m.), London Throat (9.30 a.m.), Cancer (2 p.m.), Throat, Golden Square (9.30 a.m.), Guy's (1.30 p.m.).
- THURSDAY.**—St. Bartholomew's (1.30 p.m.), St. Thomas's (3.30 p.m.), University College (2 p.m.), Charing Cross (3 p.m.), St. George's (1 p.m.), London (2 p.m.), King's College (2 p.m.), Middlesex (1.30 p.m.), St. Mary's (2.30 p.m.), Soho Square (2 p.m.), North-West London (2 p.m.), Chelsea (2 p.m.), Great Northern Central (Gynecological, 2.30 p.m.), Metropolitan (2.30 p.m.), London Throat (9.30 a.m.), St. Mark's (2 p.m.), Samaritan (9.30 a.m. and 2.30 p.m.), Throat, Golden Square (9.30 a.m.), Guy's (1.30 p.m.).
- FRIDAY.**—London (2 p.m.), St. Bartholomew's (1.30 p.m.), St. Thomas's (3.30 p.m.), Guy's (1.30 p.m.), Middlesex (1.30 p.m.), Charing Cross (3 p.m.), St. George's (1 p.m.), King's College (2 p.m.), St. Mary's (2 p.m.), Ophthalmic (10 a.m.), Cancer (2 p.m.), Chelsea (2 p.m.), Great Northern Central (2.30 p.m.), West London (2.30 p.m.), London Throat (9.30 a.m.), Samaritan (9.30 a.m. and 2.30 p.m.), Throat, Golden Square (9.30 a.m.), City Orthopaedic (2.30 p.m.), Soho Square (2 p.m.).
- SATURDAY.**—Royal Free (9 a.m.), London (2 p.m.), Middlesex (1.30 p.m.), St. Thomas's (2 p.m.), University College (9.15 a.m.), Charing Cross (2 p.m.), St. George's (1 p.m.), St. Mary's (10 p.m.) Throat, Golden Square (9.30 a.m.), Guy's (1.30 p.m.).

### A CONSIDERATION OF SOME OF THE DIFFICULTIES MET WITH IN THE EXPERIMENTAL TREATMENT OF CANCER. (a)

By SKENE KEITH, M.B., F.R.C.S.ED.

It is said that every young lawyer has visions of sitting one day on the Woolsack, and it is probable that the dream of discovering a cure for cancer occurs at one time or another to every medical student. He dreams of the benefit to humanity and of the glory to himself.

It is a subject we have all to consider, and I have tried to put together some things about it which have occurred to me, not from the scientific investigator's, but from the practical experimenter's, point of view. One turns the subject over and over, and perhaps comes to think that one has at last settled in one's own mind something definite. Then comes reconsideration, and at once doubt appears. Still, for experimenting I believe that one must take up a definite line. Once there is a commencement, it is not so very difficult to progress and to improve. Take, for example, the X-rays; at first the difficulty was to prevent a burn. Experts can, I understand, prevent this, and a burn now means either ignorance or carelessness. Nothing shows more clearly the state of ignorance we are in than the apparently almost universally held idea when radium was discovered that here was the cure so long sought, and this before anyone knew hardly anything at all about the subject.

There are many difficulties in the experimenter's way. One great one is that it comes to few to have the opportunity of making practical experiments. An occasional patient turns up, and, if the growth is capable of being removed, no experiment can be tried. If the disease is far advanced, it may seem unkind to suggest increasing, perhaps, the already sufficient miseries. Even in hospitals this difficulty also prevails, because it is impossible to admit any but the smallest number of those who are beyond operative interference, simply for the sake of experiment, when there are so many for whom something can be done, or at least attempted.

If this difficulty has been surmounted, a much greater one immediately appears, for what is cancer? how does it come? why does it kill when there is no exhausting discharge, and when situated in a part of the body not necessary to existence?

Cancer, or widely malignant disease, is divided pathologically into two main groups—*viz.*, those spreading through the blood and those spreading through the lymphatics. Does this help us for treatment? Are we to take pathology into account in experimenting, or are we to ignore it? The amount of success which has been obtained by the administration of the toxins of erysipelas and the Bacillus

prodigious—Coley's fluid—in the treatment of sarcomata seems to point to the advisability of at least considering whether, for treatment, it may not be well to divide the cases into groups. But on the whole, pathology, even the latest discoveries of the conditions of the cells, does not at the present time, at all events, seem to help us much.

Already there are several who claim credit for first making the discovery that "the cells in malignant disease undergo a reductive division similar to that occurring in the formation of sexual cells, whereby germinal tissue is formed." It would take an expert to decide this question of priority, but it seems probable that Dr. George Beaton was the first to come to this conclusion as to the nature of the cells, the result of practical experiments, his experiment of the removal of the ovaries for inoperable cancer of the breast being based on physiological grounds; and the clinical observations he made induced him to come to the conclusion that cancer was due to a local conversion of the cells affected into germinal tissue. Here pathology is following, as so often has been the case, in the treatment of diseases.

How does it come? why has it come? to me are common questions. People can realise the infection from, say, scarlet fever, or an attack of pleurisy, or pneumonia, the result apparently of a chill, but they do not understand, if there has been no injury and no family history of the disease, why cancer should come to them. We also are faced with the same difficulty. In some cases doubtless there seems to be a distinct connection between a prolonged irritation and the occurrence of the disease, but surely there must be something more, or why does not a similar irritation produce it in all? Women often trace a connection with a blow, especially on the breast, but every woman who has cancer of the breast does not know of any injury, and many must be injured in that region without the disease resulting. No, the irritation or injury theory is not enough.

Heredity—this question opens up so many fallacies that it is impossible to dogmatise on the subject, for the same thing occurs here as with injuries; all who have a family history of the disease do not have it, and some have it where there is no known family history. My own opinion is that it is the rule rather than the exception that the tendency to the disease is handed down from one generation to another. How many people, even in good circumstances, can tell the cause of death for two generations, especially where there is a large family? But to go back two generations is probably not enough, especially if we are to accept as a fact that a disease—for example, syphilis—can be traced through five generations. There are some who do not believe that heredity plays any part, but they do not advance any theory to take its place. Is it caused by a germ or a parasite? This question is, like most others connected with the subject, still only a conjecture. What is there in the disease to cause death? Why is there the steady loss of vitality? A satisfactory answer to this question might help in our search for a remedial agent.

Is the disease in the beginning a local one, or is the growth a local manifestation of a general condition.

(a) Read before the Cambridge Medical Society, February 5th, 1904.

or is it sometimes one thing and sometimes the other? If it were local, is it probable that there would be so often a return after removal, or is it that a return always means incomplete or too late operation? If the latter, why should the disease lie dormant for years, and then apparently start into existence, sometimes with, sometimes without, any exciting cause? Whichever theory is held, in practice it must be evident that the hope, at least, is that it is a local disease. An operation performed with the expectation of accomplishing a permanent cure points to the local theory. If the local theory is held, then all idea of heredity must go, unless it is believed that the disease is due to the improper development or arrangement of some of the embryonic cells, and that the tendency to have such can be inherited, the offspring of a person born prematurely being more prone to such conditions. The possibility of this amount of heredity was suggested to me by Mr. Richard Cowen, and the idea seems to be a novel one. Otherwise the disease must have something general in its nature if it is to be handed down. The experiments we have heard most of lately all attack the disease locally; the X-rays and bromide of radium are both local in their action, and, as far as is at present known, have no power of preventing the disease appearing in other parts. At present their use seems to be limited to cases of rodent ulcer and to the removal of small nodules, either by absorption or by a caustic action, but it is a great misfortune that so many patients have had the pain of an X-ray burn—a different thing to an ordinary burn—added to the sufficient miseries connected with the close of life by cancer. It is known that the injection of quinine and other substances increases the beneficial action of the rays, so it may be that in this or in some other way their action may be extended to deeper parts. I do not think that the theory of a general condition, and with this the influence of heredity, should be ignored. It frequently happens that after an apparently satisfactory operation the disease returns as quickly as if the original growth had not been removed. One has seen so many disappointing cases of this kind that one must feel inclined to accept this theory of a general condition unless the middle course is to be taken, and we are to believe that there are two distinct causes at work, the local and the general. This would be a simple, but very unsatisfactory, way out of the difficulty.

There is, however, one point on which everyone is agreed, and that is that with the amount of knowledge we possess at present it is impossible for anyone to feel sure one way or the other.

We come to another matter which may bear much on the subject. It is the great difference there may be in two apparently identical cases in malignancy. One case runs its course in, perhaps, a year; in another the disease may exist for two, three or more years. This may be partly explained by age, in the young the course being usually more rapid than in the old, but this is not the whole explanation. The elucidation of this point would also help us towards a cure.

So far I have dealt with difficulties more perhaps theoretical than practical, but they have been considered because they lead up to the great practical difficulty of deciding or suggesting what line experiments are to take. A form of treatment, if we come to the conclusion that the disease is a local one, and which then might be sensible and appear right, could not do so if we take the line that the local growth is the result of something else.

A very practical matter has now to be considered. At the present time the recognised method of treating the disease is by operation. It is recognised in all the books and at all the medical schools that surgery, especially if the case is seen early, may cure either temporarily or permanently, and at present no one doubts that this is a proper view to take. It is, however, a view which renders all experiment difficult, almost hopeless, because the patient, when he comes to the experiment stage, is saturated with the disease and the vital powers are so much reduced that the

action of drugs seems often to be modified. In cases of this nature also, the patient and the doctor are both ready to clutch at straws and to be encouraged, by slight improvements, into the belief that a curative agent on the disease is being used when it is one which only alleviates symptoms caused by the disease. This can often be easily accomplished. Such treatment would not affect the disease in the early stages and before it has existed long enough to affect the general health. It is, however, in the early stages that one would expect that a remedy which actually combated the disease, and not the results of the disease, would have most chance of effecting a cure, and as an example of this the following cases may be mentioned. The two cases were those of a husband and wife, both being just under forty years of age. The mother of the wife had died of cancer of the stomach. On the husband's side there was no history of cancer, as far as he could ascertain. The lady had noticed a lump in her right breast some months before she first consulted a doctor. By this time there were two ulcerated patches, said to be roughly the size of a shilling, on the breast. The first doctor consulted gave the opinion that no operation was possible, as there was a mass connected with the ribs. A hospital surgeon gave a similar opinion, and this was confirmed by a third. At the first visit the lump in the breast was the size of half a hen's egg; the mass connected with the ribs was very large. It felt about an inch thick, and was fully four inches in diameter. There was little pain, but great loss of strength and weight. In such a case, an experiment would be recognised by everyone as being a fair thing to try, and a form of treatment by hypodermic injection of various drugs, and which my brother and myself have been experimenting with since the beginning of last year, commenced. The case improved steadily, the ulcerations healed, the mass in the breast disappeared, and the one connected with the ribs was much reduced. At this time, after the wife had had twenty-seven injections, the husband came to show his tongue, as it had been painful at night and had looked ulcerated for five weeks. An irregular ulceration with a hard base three-quarters of an inch long and a quarter of an inch wide was seen on the edge of the tongue. There was no history of syphilis—the patient fully realised the necessity of being truthful on this point—nor were there any evidences of it to be found. To be on the safe side  $\frac{1}{4}$  gr. of perchloride of mercury was ordered to be taken three times a day. For about one week the ulceration looked cleaner, but continued to increase in size, and after three weeks of this treatment the ulcer was over an inch in length. The treatment now lay between removal of half of the tongue back to the hyoid bone, or a trial of an experiment somewhat similar to what his wife had been undergoing. Eleven injections removed entirely the hard base, and healed the ulcer, while at the same time the pain was relieved completely. For the time being the case is cured, but as time alone will show if the cure is permanent I only bring it forward at present as an indication of how much greater and quicker the results may be expected when experimenting on early cases; nor do I wish to enter into the question of whether one is justified in advising an experiment in a case suitable for operation. My object is rather to suggest the advisability of experimenting on cases of cancer of the liver, especially when they are seen in the early stages of the disease, or in any other part where an operation is neither possible nor advisable for any reason. For example, the removal of deeply seated malignant growths in the neck is seldom a satisfactory operation, and an experiment on such a case might be considered to be as likely to do good as an attempt at removal. The only objection there seems to be to doing this is that it is by no means easy to make the diagnosis in the early stages, especially when the disease is situated in an internal organ of the body. In other respects there does not seem to be any objection, because the patient does not lose any valuable time, and thus, while an experiment may do no good, it need not result in any harm.

Until quite recently it might almost seem that hope of discovering a cure for this dread disease had been abandoned, and that all attention was being concentrated on improving the methods for its removal. In this direction there can be no doubt that there has been a decided advance, though the pendulum has swung too far, and now, instead of removing too little, the operations are sometimes unnecessarily too severe. Even the public institutions specially devoted to the treatment of cancer appear to have contented themselves with doing their best for the individual patient by improving their methods, but always on the same lines.

Privately, it is probable that many experiments have been made, but in so far that they have come to nothing there has been no occasion to say anything about them. My brother and myself have been experimenting for a number of years both with possible remedies we had ourselves thought of, and also with those suggested by others. Some day we hope we may be able to bring forward the details of something satisfactory, but failure, repeated time and again for over fifteen years, teaches one to be in no hurry to be enthusiastic, and the more one works at the subject the more difficult it seems to be to know when a cure can be claimed, or, indeed, to feel at all sure that one knows anything very definite about the subject.

The question of the greatest practical difficulty has been already referred to—*viz.*, that of not getting the cases early. Patients come after they have tried to believe in the so-called Christian Science, but their faith has probably been weak—after X-rays, high frequency, and operations, with a quick pulse, a yellow skin, and all the symptoms of an early parting of the ways—and they ask can nothing further be tried for them. It is distressing to have to say that there is no treatment for such a case, but what is the use of trying to cure any patient in the last stages of the disease? The question of the curability of cancer has been taken up by the daily papers. This publicity is not altogether a misfortune, because, by making patients think that a cure may be found out some day, or may be in the process of being found out, they are, at least in our experience, more anxious to try an experiment than they were before the special cancer hospitals and the Royal Colleges began to experiment and investigate. As experiments cannot be made without money, the public have had to be taken into the confidence of the profession. These public appeals have given rise to hope; patients who formerly would have been resigned when told that nothing could be done for them are now inclined to try something—anything. So long as the experiments are properly carried out, and the patient fully realises that it is experimental, no harm need be done. But it is different when a treatment about which we understand little, such as exposure to the X-rays, is undertaken by incompetent persons. Much harm may and has been done, and many painful burns and a number of deaths have resulted from the careless or ignorant use of the rays. It is apparently forgotten that every care must be taken to prevent an experiment doing harm. I do not wish it to be understood that I would not approve of the X-ray experiments being continued. Very far from it, but I would ask that unqualified persons should not be allowed to treat patients with a force which not only may cause most painful burns, but which has actually caused death in a number of instances, from sudden absorption of the breaking down tissues of the growth itself.

When one writes of a cure being discovered, nothing sudden is meant. It is difficult to see how it is possible to discover a cure without some years of patience, for one cannot fairly say that any patient is cured until some years after treatment. It is on this question that one can legitimately complain of the lay papers. Cures have been reported; for example, one doctor was stated to have announced that he had cured several cases by the use of radium, and we all know that radium has been discovered for months rather than years; someone else has discovered the cure in salt;

another in molasses, and so on. It is not likely that any doctor with any reputation to lose has given out statements of such a kind.

I have shown that the treatment of cancer has been almost entirely directed to the cure of the local condition. It would be foolish to say that everything has been done locally that can ever be done, but I would suggest that more attention be given to experimenting as if the disease were a local manifestation of a general condition. If we knew why the disease caused loss of strength, loss of weight, and deterioration of the blood, it might be that we would be near to the discovery of a curative agent. At present, investigations have not reached this point of the subject.

Our own experiments, passing by the more scientific aspects of the question and limiting ourselves simply to attempts to discover a curative agent, have been directed since the beginning of last year to attacking the disease through the general condition.

Experiments may be divided into the following groups:—First, cure of the disease; second, relief of symptoms; and third, improvement in the general or local condition, or of both, so as to bring an inoperable case within the range of surgery, to be followed by further treatment in the hope of effecting a permanent recovery. An example of the first has been already given, the cure at present being a cure only in so far that there are no symptoms and no sign of disease. An example of the second was a case of extensive cancer of the liver, where there was severe pain, great loss of strength, and deep jaundice with distressing skin irritation. Though the treatment was begun less than three weeks ago, the pain has been entirely relieved, the strength has come back so much that the patient can walk out alone, which she had not done for some months. The jaundice is less and the irritation is almost completely relieved. In other words the life of the patient will not only be prolonged, but will be prolonged in comfort. An example of the third was that of a lady, *æt.* 55, who had known of the presence of a fibroid tumour of the uterus for nine years. In October, 1902, she was told that she had cancer of the womb and that an operation was impossible. This was confirmed some months later. I saw her in the beginning of December, 1903. The patient was greatly emaciated, very anæmic, and very yellow. The pulse was 108, running up to 120. After consultation with my brother, it was agreed to try preliminary treatment, and then, if possible, remove the uterus. The pulse came down to a steady 92, the anæmic condition improved, and the yellow discoloration of the skin disappeared, and I was able to operate in the end of January of this year. In December an operation would have been indefensible.

So far as we have gone, results have been very satisfactory, but I have purposely not entered into details, because in the past investigators have been far too ready to proclaim success which time has shown to have been premature, and we think that it would be better for everyone in the long run if experimenters were allowed to go on quietly until they had something definite to say, and something which had stood the test of several years rather than, as at present, of only a few weeks.

(NOTE, July 23rd.—There has been no return of the disease in the four cases referred to.)

### THE PRESENT POSITION OF RADIUM IN THERAPEUTICS, WITH A *RÉSUMÉ* OF THE FINSEN LIGHT AND X-RAY TREATMENT. (a)

By C. M. O'BRIEN, M.D., L.R.C.P.,

Physician to the City Hospital for Diseases of the Skin and Cancer, Dublin.

In December, 1902, I had the honour of reading a paper before this Academy on a year's experience of

(a) Read before the Section of Medicine in the Royal Academy of Medicine in Ireland, Friday, May 13th, 1904.

the light treatment in which I described my method of applying both the Finsen light and X-rays, discussing in brief the conditions in each case which appeared to me favourable to the adoption of one or other or both the methods. I found it difficult then, and it would be much more difficult now, to discuss either method separately, for in the general routine of hospital non-selected cases the two methods of treatment markedly overlap, and with best results.

Times beyond count the physician is confronted with the crux in this new case. Which method should he employ—the Finsen light or X-rays? and frequently the question founded on experience irresistibly suggests the answer “use both.” In all such cases (and they are many, especially in lupus), needless to say sentiment and hero-worship must be suppressed and the best method, or a combination of the best methods, only employed in the interest of humanity. In the discussion that ensued on that paper it was suggested that I should again bring forward the cases then exhibited, and in compliance with that suggestion I have the honour of now submitting for your inspection a few who were within easy reach, while holding written replies of a reassuring nature from most of those who have returned to the provinces, where they are at present pursuing their avocations on terms of equality with other members of the community, some after a lapse of twenty-eight years.

CASE I.—A girl, *æt.* 24. Condition on admission to the Skin Hospital in May, 1902: She presented an extensive, yellowish, dark incrustation, involving the *alæ nasi*, tip and bridge of nose, the prominences of both cheeks and greater part of upper lip, the nasal cavity being much encroached upon by lupoid vegetation. The lupus was of four years' standing. She had been operated upon four times under chloroform prior to her admission to the light treatment. She received the Finsen light to the face and X-ray exposures to the nose.

CASE II.—A girl, *æt.* 31. Condition on admission to the Skin Hospital in December, 1901: The lupus had involved both cheeks with considerable destruction of the *alæ nasi* and septum; connecting the patches on both cheeks a band of ulceration, horseshoe in shape, was perceptible, involving the greater part of the bridge of nose. The disease was of sixteen years' standing and had been surgically treated twelve times before her admission to the light treatment, which included both the Finsen light to the face and X-rays to the nose.

CASE III.—A girl, *æt.* 21. Condition on admission to the Skin Hospital in April, 1902: She presented a small, well-defined ulcer involving right *ala nasi*, and extending up right nasal cavity, the mucous membrane of which was swollen, granular, and bled easily. The lupus was of five years' standing, and had been operated on four times under an anæsthetic prior to her admission to the light treatment. She received both the Finsen light and the X-rays.

CASE IV.—A boy, *æt.* 13. Condition on admission to Skin Hospital, December, 1901: He presented a circular ulcer something larger than one shilling situated on left cheek; the edges of ulcer were infiltrated and its base contained typical apple-jelly nodules. The disease was of nine years' duration and had been surgically operated upon under anæsthetics six times before his admission to the light treatment—he received the Finsen light only.

*Memo.*—Of the foregoing cases presented to you for re-examination this evening, and whose histories were given in greater detail, with illustrations, in my former paper, no treatment has been given for nearly a year with the exception of Case I, in whom the disease recurred in the mucous membrane of nose and to whom the high frequency current is at present being applied.

The foregoing *résumé* of the light treatment brings me to the subject of my paper to-night—radium, the latest therapeutic remedy upon which medical science has been called on to adjudicate. This remedy has already received so much notoriety in the lay press that I consider it both opportune and necessary that its therapeutic results should be recorded at once with

accuracy by operators who have tried it, and whose method of procedure has been open to the inspection and investigation of the profession. Thus we spare public feeling the pain of disappointment so often the outcome of sensational exaggeration, while at the same time safeguarding from disfavour and probably disuse a method I believe we are justified in assuming is potent of promise.

I shall not tire you with the history which led to the discovery of radium, with which the names of Madame and Monsieur Curie are so inseparably associated; but what appears to me the most characteristic feature associated with it, and with most of the great discoveries of our own times, is the sequence with which the one led up to and followed the other, compelling Nature, as it were, to divulge her secrets, while at the same time serving as finger-posts to future research.

In 1882 Koch discovered the cause of consumption, and eight years later he declared he had found its cure by injecting tuberculin.

In 1894 Finsen, after years of patient experiment, proclaimed that by concentrating certain rays of the solar spectrum he could kill the bacillus which Koch had found, but failed to conquer.

In 1895 Röntgen convulsed all Germany, and, indeed, the scientific world generally, by his statement that he had discovered rays which could render the human body transparent.

In 1896 Becquerel discovered that uranium emitted rays akin to the Röntgen rays, but weaker, and it was doubtless this important link in that chain which led to the discovery of radium by the Curies two years later.

I shall not dwell on the physical or chemical properties of this great metal, excepting so far as they apply to practical medicine. The power possessed by radium of emitting rays which manifest different penetrative and therapeutic effects is the one property of all others which most strongly appeals to the physician. Whether or not these rays are identical with X-rays is a matter upon which much diversity of opinion at present exists. I am indebted to Dr. Reginald Morton for a copy of a paper kindly sent me, in which he discusses this difficult and important question most clearly and concisely.

An approximate knowledge of the penetrative power of radium rays may be obtained by the ordinary X-ray screen in a dark room. With my own specimen of 5 milligrammes, all I could possibly procure last September of a trustworthy standard, this specimen when held half an inch behind a bar of metal,  $1\frac{1}{2}$  inch thick caused distinct fluorescence of the ordinary X-ray screen, and when held at a distance of three or four inches behind the screen, and the hand interposed between the radium and screen, the general contour of the hand becomes manifest but to a much lesser extent than in the case of X-rays. These experiments are not only interesting, but easy to make.

Unfortunately the supply of radium is so limited that even in the out-patient departments of large skin clinics much difficulty is experienced in procuring suitable cases for this method of procedure. Hence operators are precluded even now from dogmatizing on its therapeutic merits.

The method and duration of its application were additional difficulties which early workers had to encounter, and the difficulty in definitely fixing a period of application which will apply equally to all is well illustrated in the history of my cases given below. Where different patients with like disease, similarly situated, had the same specimen of radium applied under like conditions to patches of lupus of equal size and depth, neither of which were previously treated, in the one case twenty applications of ten minutes' duration were sufficient to establish a cure, while in the other twenty applications of ten minutes' duration were insufficient to create any alteration, excepting slight redness and itching. It may be that personal susceptibility of patient, so important a factor in the Finsen light and X-ray methods, may also have to be reckoned with in the treatment by radium rays.

CASE I.—A male, *æt.* 30, unmarried, clerk, has been

the subject of extensive lupus of the face for twenty years, during which time he has been applying nitrate of silver and other caustics weekly, and has had it scraped under an anæsthetic seven times. He is at present receiving both the Finsen light and X-rays, and is steadily yielding to this course. About two years ago he developed a patch the size of a sixpenny piece over right eye-brow, close to the orbital margin and inner angle of the orbit. The patch was circular in shape, with irregular edges, which were slightly raised above surrounding skin, and capped with a yellowish crust in centre. The position at once suggested treatment by radium because of the extreme difficulty of applying either the Finsen light or X-rays.

On December 16th, 1903, having removed the crust, I applied in close apposition with the patch five milligrammes of radium bromide in a vulcanite capsule, with a circular window of mica, for easy transmission of the radium rays.

From December 16th, 1903, to February 10th, 1904, he had in all twenty applications of ten minutes' duration. Nothing perceptible had occurred in the progress of the case until the end of the fifth week, when the edges of patch became more prominent, slightly redder and an itchy sensation was complained of, with a slight discharge from the patch for the first time. The further treatment was persisted in and five additional applications given, of the usual duration and at intervals as before.

On February 10th, the date of last application, the edges of patch were more swollen and redder, and although the itching had practically ceased, the patient complained of stiffness of the muscles, which became more manifest on wrinkling the brow. The discharge referred to before meantime increased. The treatment was now stopped, swelling and discharge subsided, and three weeks later the patch, although still red, had assumed the appearance of a healthy scar; no external applications of any kind were applied prior to, during, or since the treatment above described.

CASE II.—A girl, æt. 16, was admitted to the Skin Hospital, December 21st, 1903, suffering for about seven years from a patch of lupus, the size of a sixpenny piece, of a reddish colour, with raised edges covered with branny scales. Patient suffered no pain; she sought treatment only because she thought it was beginning to spread and becoming more unsightly. On December 21st, 1903, five milligrammes of radium bromide were applied in direct contact with patch, there being no discharge from sore in this as in the former case which could in any way diminish the radio-activity of specimen employed. Between December 21st, 1903, and March 18th, 1904, sixty-one applications were given.

First month, five applications weekly of ten minutes' duration without manifesting any visible change, excepting a slight redness.

Second month, twenty applications of thirty minutes' duration were given, the redness of margin becoming more pronounced, accompanied by itching but no discharge. February 13th, duration of application was increased to forty-five minutes, of which fifteen such applications were given, with the result the edges of patch became swollen, with the sensation of pins and needles in part, and a discharge on pressure. Treatment was still continued and six further applications were given of sixty minutes each, the last on March 18th, when the treatment was stopped. A week later the pain, swelling, and discharge had diminished. The base of ulcer was clean and healthy-looking, but the edges somewhat raised.

No treatment or external applications of any kind were applied prior to, during, or since the treatment mentioned.

#### CONCLUDING REMARKS.

Radium, to be of practical use in the cure of disease or the alleviation of human suffering, must be forthcoming in much larger quantities, of a recognised standard of activity and at a very much cheaper rate.

From my own experience of the metal, I prefer detailing what I have already achieved and how I achieved it, rather than expressing an opinion on its merits which might in any way circumscribe its sphere of application or prevent others from putting it to the test.

For diagnostic purposes it is very doubtful if radium can ever be of much use. With the X-rays we have much ground for hope in both lupus and rodent ulcer, and combined with Finsen light the results recorded are becoming more universal and more reassuring.

In my previous paper I expressed the belief that the Finsen light for circumscribed superficial lupus had no equal; now, after eighteen months further experience, I am more convinced than ever of its efficacy. But it will be for you, ladies and gentlemen, to say whether or not I have claimed for the method more than my results justify.

#### NEW

### METHODS OF TREATMENT. (a)

(1) SCROFULOUS FISTULA; (2) SCROFULOUS GLANDS; (3) ANÆMIA AND CHLOROSIS; (4) SPASMODIC CONVULSIVE AFFECTIONS.

By LUCIEN WEYLL, M.D.,

Bad-Schwalbach.

FOR all affections of the external organs or affections accessible to external treatment, permanent local baths are of indisputable value.

(1) For many years surgical and gynecological affections have been treated successfully by this method; there is only one affection for which this treatment is not yet sufficiently recognised, that of open scrofulous glands. A great number of these glands treated by this method have, under my care, cicatrised in a short time.

Submaxillary glands open for about one and a half year; (although already operated on) were radically cured within a fortnight.

Sublingual glands, running for several months too, healed within a short time.

The local baths were taken hot (temperature about 86° F.), one to two hours, with a minimum of sublimate, so that the concentration was of 1-100,000.

(2) For closed scrofulous glands I recommended at the Congress, as I had done before in the *Therapeut. Monatss.* of 1900 vaporised sublimate inhalations; concentration, 1-100,000 (the limit of antiseptic effect of sublimate being 1-500,000).

(i) Submaxillary gland, walnut size, inhalation of sublimate vapours three times a day for half an hour. Within six weeks radically reduced.

(ii) Submaxillary glands on either side, walnut size. Within two months almost entirely reduced.

(iii) Sublingual gland, walnut size, reduced after a fortnight's treatment.

Glands of greater dimensions are, of course, not so easy to reduce, the most susceptible to this kind of treatment being the soft and small ones of children; if particularly obstinate they may be made to suppurate, and then treated by the method of bathing mentioned before.

What concerns sublimate vapours inhalation in case of initial catarrhal affection of lungs? (See my article on this subject, *Therap. Monatss.*, Prof. v. Liebreich.) Sublimate 1-100,000, not pulverised but vapourised, and so entering into the finest branches, will be found to be a really

rational method, the antiseptic effect here not being diminished by the circulation.

(3) Subcutaneous injections of ferrum lacticum (1 per cent.) in cases of obstinate anæmia or chlorosis.

(i) Anæmic girl, æt. 20, treated for six months with internal ferruginous medicaments, without success; after ten injections red-coloured cheeks.

(ii) Lady, æt. 25; very anæmic; ferruginous medicaments and water useless; after twenty injections coloured cheeks, &c.

Injections being sometimes painful, they ought to be mixed with cocaine.

(4) *Spasmodic convulsive affections*, by which I mean chololithiasis, asthma, epilepsy, and whooping-cough; though these affections do not seem to have anything in common, being different in their origin, asthma and epilepsy sometimes breaking out without any organic cause, while chololithiasis and whooping-cough are occasioned by grave organic or infectious alterations, yet finally they reveal themselves as an expression of cerebral irritation, whooping-cough, asthma and chololithiasis attacking the deeper vagus regions, whilst epilepsy is more concerned with the superficial motor centres.

## SOME OBSERVATIONS ON THE MODE OF ORIGIN OF NASAL POLYPI. (a)

By EUGENE S. YONGE, M.D. Edin.,

Honorary Assistant Physician, Manchester Hospital for Consumption and Diseases of the Throat.

THE central idea, in this investigation, was to endeavour to find some of the processes which immediately preceded polypus formation, and to trace the progression of the disease from normal mucous membrane up to the fully-formed "growth." Observations were made both on the cadaver and on specimens obtained from clinical cases.

The cases from which specimens were obtained for microscopic examination, or which were otherwise investigated, may be divided as follows:—

1. *Cases in which the Nasal Tissues were not Diseased*.—Obtained post-mortem. Fœtus, infant, young adult, &c. Also mucous membrane from all the accessory sinuses.

2. *A Case of Early Nasal Polypus*.—No accessory sinus disease. Obtained post-mortem.

The outer walls of both nasal cavities were examined, and a number of sections were cut in successive antero-posterior planes.

There was a condition of chronic inflammation of the various turbinal and meatal tissues, with the exception of the inferior meatus, which was practically normal. The mechanical process of polypus formation could apparently be traced from smooth (non-polypoid) mucous membrane to structures which showed the characteristics of ordinary mucous polypi. The tissues were œdematous in the areas generally selected by mucous polypi for their site of origin, and the vast majority of the mucous glands were degenerate and dilated. Other appearances, such as enormously thickened vessels in the middle and inferior turbinal regions, were also noted.

It was further observed that polypi appear to

owe their shape, their number, and other characteristics principally to the manner of the initial process of their formation—*viz.*, œdema of the mucous membrane of the part affected, which, in a normal condition, is folded. These folds, when œdematous—that is to say, when sharing in the general œdema of the mucous membrane—gradually assume the appearance of blunt, finger-like processes which correspond in structure to incipient mucous polypi.

3. *Clinical Cases of Nasal Polypus, at various stages*, in which certain of the tissues were examined.

These included (a) polypi associated with accessory sinus suppuration; (b) polypi not so associated; (c) tumours having a similar macroscopic structure to the usual mucous polypi, but growing from the inferior turbinal.

The groups (a) and (b) seemed to have a similar mode of origin. Cystic degeneration of the glands was more marked in the sinus polypi than in the other variety, whilst simple fatty degeneration was observed in both. The inferior turbinal polypus differed from the middle turbinal and meatal polypus in the same manner as the histological structures of the parts differed from each other, so that the former variety was composed of a much firmer, thicker and denser tissue. Dilated glands were observed in both.

4. *Cases of Chronic Inflammatory Conditions of the Nose unattended by Polypus*.—Chronic catarrhal rhinitis may be taken as a type. The conditions observed in the middle turbinal and meatal regions—which may be regarded as the usual sites of polypi—differed from the appearances seen in the same regions when polypi were present in an early stage, chiefly in the following particulars:—

(i) A mucous membrane which, especially in its superficial (sub-epithelial) layer, was not œdematous.

(ii) Active glands as opposed to degenerated and dilated glands. In a few instances, cloudy swelling was noted in a few glands in the section, but usually they were normal.

On the other hand, the instances of chronic catarrhal rhinitis resembled those of polypus, in all the signs of chronic inflammation, and, so far as the writer could judge, in every other condition except in the two respects noted above.

5. *A Case of Chronic Atrophic Rhinitis*.—Obtained post-mortem.

6. *Instances of "Polypus" in other Parts of the Body* (stomach, uterus, rectum, and middle ear).—The writer's observations seem to point to the conclusion that the excrescences which are found in the stomach, in the rectum, and in the middle ear, and which are generally classed as "polypi," have one point—the name—and occasionally a second—the shape—in common with nasal polypi, but that otherwise they differ radically from the growths found in the nose. In polypus of the cervical portion of the uterus, however, there is a close resemblance in structure to the corresponding condition in the middle turbinal region, except that in the former the tissues are somewhat less œdematous than in the latter.

Aural polypi are composed in every instance of ordinary or, later, of organised granulation tissue (Lake); and their structure is, consequently,

(a) Read at the Annual Meeting of the British Medical Association, held at Oxford, July, 1904.

fundamentally different from nasal mucous polypi, properly so called.

*Provisional Conclusions.*

As a result of his observations, the writer suggests the following conclusions:—

1. Mucous polypi of the nose, in the large majority of instances, are consequent upon inflammation of the mucous membrane of the nasal cavity.

2. The process of polypus formation is partly mechanical and partly degenerative.

3. The primary process is a localised œdema of the inflamed mucous membrane, which œdema, chiefly on account of certain known structural peculiarities of the lining membrane, does not, in the greater number of cases, occur in any intranasal area, but that of a limited portion of the middle turbinal and of the middle meatal regions. Analogous structural peculiarities are present in the mucous membrane of some of the accessory tissues.

4. The determining cause of the occurrence of the œdema, in the regions specified, is the degeneration and dilatation of the mucous glands. The following evidence appears to be in favour of this: (i) The abundance of degenerated and dilated glands in the mucous membrane subjacent to and in the immediate neighbourhood of polypi. (ii) The definite and proportionate ratio between the amount of glandular degeneration and the amount of œdema. (iii) The presence of abrupt and isolated patches of œdema, which exactly correspond with isolated groups of underlying degenerated glands. (iv) The presence (in some sections showing two surfaces of a turbinal) of œdema on one side and firm non-œdematous tissue on the other—the œdematous side being supplied with degenerated glands and the firm tissue with active glands. (v) The absence of œdema (a) when the glands are healthy and, generally speaking, in the areas where there are no glands present; (b) in cases of chronic rhinitis where the glands are not degenerated. (vi) The concurrence of this sign in both varieties of polypus ("sinus" and "non-sinus" polypus). (vii) Lastly, the possibility of explaining the œdema, on the hypothesis of these glandular changes, on account of the peculiar arrangement of the glandular blood-vessels, combined with the peculiar histological disposition of the tissues in which the glands of the "polypus regions" lie.

5. The peculiar shape and some other characteristics which polypi assume is due to their mechanical inception as œdema of the normal folds of the mucous membrane.

## THE CARE OF CHILDREN'S MOUTHS. (a)

By SIDNEY SPOKES, M.R.C.S., L.D.S.

AN examination of 10,000 children of an average age of twelve years showed that only 15 per cent. had sound teeth. Dental caries must be regarded as the most frequent departure from the normal physiological standard. Periodical inspection and early treatment are the best methods in default of absolute prophylaxis. Especially should the first permanent molars receive attention. They are situated in the jaws where the functional capacity is greatest. They "keep up the bite" at the back of the mouth during the transitional

period from the temporary to the permanent dentition and should be carefully watched from the seventh year upwards. It is rare to find caries of the other permanent teeth before the twelfth year. A periodical inspection also allows of the opportunity for observing any commencing irregularity in position which itself threatens to promote decay, and it also enables an opinion to be formed as to the extent to which the tooth-brush is properly used. In many parochial schools this system of inspection and early treatment is now carried out with good results, and as it appears probable that Board School children will soon be medically inspected, it is to be hoped that they may also receive dental supervision, and in this respect enjoy the same advantages as the children immediately beneath them in the social scale. Boys in the great public schools should pay a visit to the dentist early in the holidays in order to allow sufficient time for any treatment which may be found necessary, but it is well that there should also be an officially appointed dental surgeon on the staff of all such schools to examine and report upon the teeth of new arrivals and to deal with any cases which may occur through neglect and urgency. This prompt treatment of early caries prevents a vicious circle being established through the increased acidity of the mouth which accompanies untreated cavities of decay and thus promotes decay in other teeth as yet unaffected. Here again, it is most important that cavities, if existing, should be discovered and treated in the early stage. If a tooth has "ached" through irritation of its pulp the best time for stopping the cavity has already passed, but by prompt treatment and systematic inspections until adult age is reached it will be found that the tendency to decay seems in many instances to become considerably less.

## Clinical Records.

### CASES IN HOSPITAL PRACTICE.

By JOHN W. MARTIN, M.D.,  
Hon. Medical Officer, Jessop Hospital for Women, Sheffield.

*Bad Hæmorrhoids.—Severe Bleeding with and between Motions.—Retroflexed and Retroverted Uterus.—Both Ovaries enlarged, cystic; prolapsed.—Operation.—Recovery.*

C. H., æt. 37, married, four children, the last æt. 4. Notes taken May 24th, 1904.—This patient first came under my notice in the autumn of 1903, when she was suffering severely from piles and a constant loss of blood with and between the motions. She was worn to a shadow and very anæmic. She had seen no periods for four years. I operated upon the piles with clamp and cautery, and she made a good recovery, the operation being successful for the object in view.

She had then retroflexion of the uterus, and both ovaries were enlarged and prolapsed. The rest in hospital whilst under treatment for the piles seemed to relieve her of a good deal of her pelvic troubles, pain in the back and iliac regions.

She again came under my care in the early part of May, and was admitted into hospital. She could not wear the pessaries with which an attempt was made to retain the uterus in its proper position. There was both retroflexion and retroversion present. The ovaries were both much enlarged and prolapsed, and very tender to pressure. Suffering a good deal from pain in the lumbar, hypogastric, and iliac regions. The pains extended down the legs. She had suffered a good deal from diarrhoea before she came in, but the bowels became constipated after admission. Her general health was very poor.

(a) Abstract of Paper read in Section of Dental Surgery, British Medical Association, Oxford, July, 1904.

As she could not wear an instrument, and as treatment had been tried for some time before admission, I operated on Friday, May 27th, 1904. I found both ovaries very much enlarged and cystic, and removed them. I did a ventro-fixation. The patient made an uneventful recovery.

July 20th, 1904.—I saw the patient to-day. She is looking much stronger and better. She is putting on flesh. She is quite free from pain, and feels cheerful and active, and says that it is years since she felt so well.

## British Health Resorts.

### V.—TEIGNMOUTH.

[BY OUR SPECIAL MEDICAL COMMISSIONER.]

TEIGNMOUTH is "the first of the true West Country ports." (a) It is admirably situated at the junction of the picturesque estuary of the River Teign with the English Channel. The greater part of this attractive little town of 8,540 inhabitants lies open on the east to the sea. On the north and north-west it is sheltered by the heights of Haldon. It is well equipped with sea coast promenade, pier, lawns and walks. Not only is it linked to the past (b) by memorable associations, but forms a delightful centre for the requirements of the present. (c)

Dr. F. Cecil H. Piggott, the present M.O.H., has furnished us with valuable details concerning much that makes for the well-being of the health seeker. The birth-rate is 15.5; the net death-rate 17.08, but allowing for the mortality of non-residents is only 15.45; the zymotic death-rate is 0.58; the infantile death-rate, however, is 127.82. The water supply until recently has been "intermittent and somewhat limited." (d)

An agreement has now been arrived at with the Paignton U.D.C., whereby a constant supply of pure water will be brought from Dartmoor. Efforts are being made to secure a greater degree of purity of the Teign estuary.

The meteorological returns throw much light on climatic conditions. The mean temperature of the past year was 51.5; the mean temperature for the past thirty years, as taken from the records of Dr. W. C. Lake, was 50.6; the maximum temperature was 77.1; the minimum 26.0; the rain fall for 1903 was 40.07 inches, but eighteen years' average is given as 34.8, with 156 as the number of wet days.

Teignmouth is a particularly desirable holiday resort. It offers opportunities for excellent and safe bathing, boating, fishing, and the usual delights of a marine residence. It is a remarkably convenient centre for railway, steamer, driving and walking excursions. The proximity to the bracing highlands of Dartmoor should be remembered. Access to Torquay and other well-known Devon resorts is easy, and the Dart can be readily reached. (e)

It will be seen that Teignmouth, while principally appealing to the town dweller seeking recuperation and restoration and relief from the rush and worry of a wearing life, can also offer much that is desirable for the convalescent and the invalid. High, cold and dry east winds are said to prevail in the spring, but even then protection can be afforded by the sheltered "coombes." The hotel accommodation is somewhat limited, but there are numerous apartments suited to the requirements of the health seeker. For cases desiring a bright, warm, picturesque South Coast

(a) "Highways and Byways in Devon and Cornwall." By Arthur H. Norway. London: 1898.

(b) "Teignmouth: its Past History and Present Interests." By Beatrix F. Cresswell. London: The Homeland Association. 1901.

(c) See "South Devon and South Cornwall." By O. S. Ward and M. J. B. Baddeley. London: 1902. Black's "Guide to Devonshire." London: 1898.

(d) "The Climates and Baths of Great Britain." Vol. I. London: 1896.

(e) Consult *Devonia*, the official organ of the United Devon Association. July, 1901.

marine resort with opportunities for enjoying much variety in out-door life, Teignmouth is most suitable. In summer the place is frequented by children and holiday-makers, and there is much to attract those who need to be "taken out" of themselves. Teignmouth is some 209 miles from London. Comfortable through carriages run from Paddington on the G. W. Railway in about five hours. Access may also be had by the L. & S. W. Railway, Waterloo to Exeter, in three and a quarter hours, and thence over the G. W. system. There are now excellent arrangements for travellers from the North by means of the Midland and London and North-Western railway systems.

## France.

PARIS, August 7th, 1904.

### TREATMENT OF PHLEBITIS.

THE treatment of phlebitis, says Dr. Huchard, is one of the questions which particularly interests practitioners. Death by thrombus is rather frequent in the first stage, before even the diagnosis of the affection can be made; consequently, it is at this period that rest should be enjoined. In every woman recently confined, in every patient recovering from an infectious malady, or even outside these conditions, every pain felt in the inner part of the thigh, in Hunter's canal, beneath Poupart's ligament, or in the calf of the leg, especially if the pain is accompanied with a sensation of weight and impotence, increasing in the upright position, demands an attentive examination of the principal venous trunks of the limb. The slightest œdema or cylindrical induration, or even a smart pain on pressure over the course of the vein, should make the attendant suspect the existence of phlebitis at the obliterating period, and without waiting for further developments he should not leave the patient before placing the limb in a position of absolute rest.

Let us suppose one of the most ordinary cases—one limb alone is affected. A series of sufficiently hard cushions should be procured, with which is formed a perfectly even inclined plane. A sheet doubled two or three times is placed on the cushions so as to form a good splint, over which is spread oilskin or mackintosh, and on this a layer of cotton wool large enough to completely envelop the limb. The leg is laid gently on this cotton and covering, and when well enveloped a bandage is applied.

With this apparatus, complete extension should be adopted for fear of subsequent stiffness of the joints; the sole of the foot should be supported by a vertical board and the weight of the bedclothes kept off the toes.

As local treatment, concentrated solution of hydrochlorate of ammonia as compresses has given but little result. It is otherwise with certain sedative oils, belladonna, hyoscyamus, &c. They should be renewed three times a day and covered with oilskin.

As general treatment, the tincture of hamamelis virginica, five or six drops twice a day, and continued for months, will be of some benefit and encourage the patient. Collargol spread on as an ointment (15 per cent.) can be employed in infectious phlebitis. Against pain in phlebitis of rheumatic origin M. Oddo recommends aspirin in doses of 30 to 40 grs. daily. Veronal, 10 to 12 grs. at night, exercises a sedative action on the cramps. Valerianate of ammonia or the bromides calm the nervous excitement, and if the œdema is very considerable salt should be proscribed.

The duration of the forced immobility depends on the state of the clot. From the sixth day the clot is

solidly attached to the wall of the vein, but frequently other segments of the veins are seized, and although pain be absent the temperature rises. Consequently, from the first stage of phlebitis the temperature should be taken morning and evening, for the slightest rise will indicate fresh trouble. The patient will not be allowed to move the leg before the twenty-first day after the last rise of the temperature.

At the same time that mobility is allowed, massage commences, at first exceedingly light, and far from the affected veins. After eight days, the massage may be a little more pronounced so as to encourage the circulation in the collateral veins, and thus act on the œdema. At the same time slight movements are permitted, commencing first in the toes, then in the ankle, and eight days after in the knee, but flexion on the thigh cannot be allowed for a long time as any motion in the hip is very dangerous as regards thrombus.

At the end of from twenty to thirty days of the treatment, the patient may quit the bed for a reclining chair and a fortnight later he can stand up; but the leg must be bandaged with a Velpau bandage.

A cure at Bagnoles de l'Orne will terminate the treatment.

#### TREATMENT OF BLEEDING PILES.

The following will be found very effective:—

Chloride of calcium, chemically pure, 2½ drachms;  
Water, 3½ ounces.

Injection into the rectum of five drachms by means of a small rectal syringe. The hæmorrhage ceases in a few hours.

Prof. Boas, who has treated twenty-five patients with this solution, recommends it strongly. The injection may be repeated if necessary.

### Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, August 7th, 1904.

#### PHYSIOLOGICAL CATALYSORS IN TREATMENT.

At the Naturforschers meeting Poehl gave the members a long dissertation on the physiological catalysors as a means of cure in the practice of medicine. He first commenced with the process of nutrition, which, he said, depended upon, and was preserved by this very natural process. A certain amount of material is taken into the body, and must remain a given time to admit of this catalytic influence in order that the necessary energy may be developed to invigorate and support life. He divides the catalysors into two principal groups, *viz.*, "positive" and "negative," or, in reference to the body, "general" and "specific"; the former influencing the whole of the body, while the latter only affects a single organ. The positive includes all the catalysors that stimulate the organs and tissues to greater activity, while the negative repress or inhibit the action of special organs, of which he gave as examples spermin (positive) and adrenal (negative). Spermin hastens the oxidising process or respiration of the tissues, which neutralises or destroys the depressing properties of the leucomaines. Adrenal, on the other hand, is a reducing catalysor, and becomes a dangerous toxin when carried into the circulation.

It is only recently these catalysors have been acknowledged as therapeutic agents, and are yet in a very premature state for general use. Those in use may be described as special catalysors and directed towards a special organ, whose functions or tissue change it is desired to alter. Those for therapeutic use he would designate as the synergetic group, in opposition to the leucomaines, such as cerebrinum, extracted from the

grey matter of the brain; thyroïdinum, from the thyroid gland; ovarinum, from the ovaries; mamminum, from the breasts, &c. Thyroïdinum catalytically affects the fat, skin, and nerve system; cerebrinum affects the excretions or metabolism depending on nerve changes, and exhibits its beneficial effects in cases of epilepsy, neurasthenia, and alcoholism; ovarinum is useful in the climacteric period; and mamminum in uterine fibromata as well as some other female diseases.

• The negative catalysors are not yet recognised sufficiently to define their therapeutic value. These comprise the toxins, among which the plasma toxin is a good example. The latest observations of Professor Tarchanoff, that these organo-therapeutics all contain a large amount of radio-activity, were further established by Poehl's own personal experience.

■ In the discussion that followed, Naunyn said that he would like more evidence on this hypothetical subject before advancing a dogma on any of the questions put forward, particularly in the reducing property of urine on photographic plates after the use of adrenalin, as well as the general effects of the leucomaines. The action of Poehl's isolated substances on the organism was not to his mind sufficiently proved.

Klemperer said that he had never observed the blood becoming more alkaline after the use of spermin, which would of necessity result according to Poehl's theory.

Poehl, in his reply, would not accept Klemperer's logic, firmly believing, as he did, in his own hypotheses.

#### THE PEST INFECTION.

Schottelins expressed himself as opposed to the generally accepted term that the pest was transmitted through the atmosphere, and took its origin from the lungs. He was firmly convinced that the pest was transmitted by local wounds taking up the infection, and thus transmitting it to the circulation. Scratches, abrasions, or slight fissures of the mucous membrane are fruitful sources of infection. He presented a few wax models he had taken while resident in Bombay to prove his assertions. All of them had some primary centre through which the poison had passed—sometimes the skin, sometimes the mouth, and others in the isthmus faucium. Slight abrasions on the mucous membrane were not uncommon. From the deeper cervical glands the infection is conveyed to the lungs, which gives rise to the doubt as to origin. Again, the white race is immune to the pest virus, as witnessed by the number of European doctors, nurses, and visitors that never take the disease, though dangerously exposed to the virus. The general condition of health and individual social hygiene are potent factors in its distribution, as the underfed and unclean are the first to suffer.

Kraus remembered a case of this nature that impressed him. A slight reddening occurred, causing a running from the nose, and finally malignant diphtheria with bubos in the neck, which confirmed the diagnosis as one of bubonic plague.

Rumpf concurred with Schottelins that the virus was easily taken in by the isthmus faucium.

Rumpel said that he had attended forty cases of bubonic plague in Oporto, and never could discover a primary lesion through which the virus could be conveyed to the circulation.

#### ANTISTREPTOCOCCUS SERUM AND RHEUMATISM.

Schmidt gave a history of fifteen cases which he had treated with antistreptococcus serum with varying success. Eight of these were subacute that had resisted all other treatment, four were acute, and three chronic. The injections consisted of 15 to 20 cubic centimetres daily for eight days. The injections were

used over the affected joints, causing reddening, swelling, erythema, &c., in proportion to the rapidity of action, and no injurious effects were observed. In six cases locomotion was early restored; in four the subjective symptoms were improved, while five had no change. He cannot say there was any specific action, but thinks that the treatment is adapted for the sub-acute cases when other remedies fail.

Kraus agreed with Schmidt in this opinion, as the greatest benefit is observed where it releases the movements of the limbs.

#### CHRONIC INTERSTITIAL PNEUMONIA.

Damsch gave a history of four cases of interstitial pneumonia having no fever or trustworthy symptom to herald its approach. Tubercle was excluded. There was no shrinking of the pulmonary tissue, only the hardening over the affected part. The consequent danger of these cases lies in the twisting of the heart and producing functional insufficiency.

Litten said that he had also met with such cases without fever, bronchiectasis, or shrinking.

Rumpf had seen such cases, but tubercle usually commenced to develop later at one of the apices.

### Hungary.

[FROM OUR OWN CORRESPONDENT.]

BUDAPEST, August 7th, 1904.

At a recent meeting of the Budapest Interhospital Association, Dr. Temesváry Rezső reported a case of DYSMENORRŒEA SUCCESSFULLY TREATED BY ELECTRICITY.

A single woman, *æt.* 23, who began to menstruate normally at fourteen, at nineteen commenced to suffer from dysmenorrhœa, without any cause except slight anæmia. For the last four years menstruation had been irregular and extremely painful, with frequent menorrhagic crises. For the last two years she had had to stay in bed for several days at each period, and morphine injections were necessary. Ordinary medical and gynecological treatment—drugs, local injections, mechanical dilatation of the cervix with curettage of the uterus and massage—had been tried without permanent result. The patient was very anæmic, hæmoglobin being 60 per cent. below the normal. All the pelvic organs except the uterus were normal. The cervical canal was tortuous and stenosed. After fifteen applications of the constant current twice a week for ten minutes, the tortuosity and stenosis of the cervical canal disappeared, and menstruation became regular and free from pain.

Dr. Waldmann Béla read a paper on the prevention of recurrences in

#### SYPHILITIC DISEASES OF THE EYE.

By the following treatment recurrence in syphilitic ocular disease, he had found, could be prevented: (1) In syphilitic disease of the choroid, mercurial inunction should be undertaken for two years, the place of inunction being varied daily. (2) The dose should not exceed 30 gr., and according to the age and constitution of the patient doses of 8 gr. or 15 gr. are better. After every ten inunctions a pause of four days may be made. The best basis for the mercurial ointment is lanolin. (3) Longer pauses than three weeks should not occur in the whole two years. A pause of three months completely nullifies the treatment. (4) Potassium iodide has no curative influence on ocular syphilis, but is directly injurious on account of the conjunctivitis to which it predisposes, and should accordingly not be given in the majority of cases. Potassium iodide has only one use in the treatment

of ocular syphilis, namely, to counteract the injurious influences of large doses of mercury.

#### THE RADICAL TREATMENT OF ULCERS.

Dr. Frater Trure says that though some ulcers on the leg heal with almost any dressing, as iodoform, airol, or xeroform, the greater number resist such treatment, or, if they heal, quickly relapse. For such, skin-grafting after thorough disinfection of the ulcer is by far the best local treatment, but whenever extensive varices are present this is also unsatisfactory. The only radical treatment in such cases is to ligature the saphenous vein according to Trendelenberg's method before proceeding to the transplantation of skin.

Siegel related a case of

#### PRIMARY SARCOMA OF THE SMALL INTESTINE.

A boy, *æt.* 3½, had suffered for three months with symptoms of obstruction, which occasionally alternated with diarrhœa. As a tumour could be felt in the ileo-cæcal region intussusception was diagnosed. Laparotomy was performed, and a hard nodulated tumour was found on a coil of jejunum. The mesenteric glands were enlarged. The tumour and 12 inches of the small intestine were resected. The child died three weeks later with general metastasis, which had involved the pancreas. A small collection of pus was found near the site of the sutures, but there was no peritonitis. The tumour was a small round-celled sarcoma, and had probably started from the lymphatics of the sub-mucosa.

These tumours are rare, the writer having collected thirty-four cases; the greater number occurred in males. The case is chiefly interesting because it is opposed to the usually accepted view that absence of obstruction is characteristic of intestinal sarcomata. They give rise neither to pain nor tenderness.

## The Operating Theatres.

### ST. MARY'S HOSPITAL.

RICHTER'S HERNIA SIMULATING CHRONIC INTESTINAL OBSTRUCTION.—Mr. WARREN LOW operated on a woman, *æt.* about 55, who had been sent up to the hospital by Dr. Alfred Benson. There was a history of the patient gradually getting thin for several months, and having attacks of pain in the abdomen. Some four days before admission the pain was very much worse, and she vomited. The vomiting continued off and on till she came to the hospital, but the bowels were opened with enemata the day before admission. On admission she was feeble, but not collapsed; the vomiting was fecal; under the thin abdominal wall were seen hypertrophied coils of intestine along which occasionally a peristaltic wave passed; there was no tenderness, and nothing could be felt *per rectum*. Although she had worn a double truss for some years, no lump could be felt in either groin, and the woman said neither of the herniæ had been down for some years. The abdomen was opened in the middle line, and underneath the incision were found congested and distended coils of small intestine, of which the muscular coats were obviously hypertrophied. On passing the hand into the right iliac fossa, the cæcum was found collapsed, as were also the lowest coils of the ileum. These collapsed coils were examined, and at the distance of some three or four feet from the ileo-cæcal valve a coil of intestine was found to be apparently attached to the abdominal wall in the region of the right internal abdominal ring: a further examination showed that part of the lumen of the bowel was tightly constricted in the aperture.

With a little difficulty this was carefully disengaged and brought out of the abdominal wound. A ring of ecchymosis demonstrated the actual area of gut involved, constituting about two-thirds of the lumen. The strangulated gut was elastic and began to gradually recover its normal appearance, and was obviously in a condition to return to the abdominal cavity; moreover, the gas in the distended coils began to find its way past the constriction and the coils hitherto collapsed were now distended with gas. The intestine was returned and the abdominal wall sewn up. Mr. Low said that the case was interesting as it illustrated a fact of which several examples had occurred lately at St. Mary's of the often insidious onset in these cases of partial hernia. This woman was not in the least collapsed and the obstruction could not be called absolute till the day before admission, although she certainly was suffering from a strangulated hernia, and, in fact, with her history, she presented all the appearances of a case of obstruction to the gut by a growth which had suddenly become blocked, her symptoms being those of obstruction rather than of strangulation. Another point, he said, was that the hernia was not demonstrable from the outside, even with one hand in the abdomen at the aperture of the ring. He pointed out that he had to be very delicate in drawing the nipped piece of intestine out of the sac, as he was unable to prophesy in what condition he would find it. This process occupied some minutes and almost necessitated an incision over the region of the hernia. He said a few words of caution as to disengaging a hernia from the abdominal side, as in such a case the constricting neck of the sac had not been divided, as is usually the case in operating in the ordinary way. He had had under his care two or three examples of Richter's hernia; they had all occurred in women. In each case there had been the same insidious origin, and the patients had not been brought to hospital till the hernia had perforated and peritonitis had occurred. Judging by these examples he thought that in quite a large proportion of partial hernia the symptoms were rather those of obstruction than of strangulation.

A week after operation the patient was doing perfectly well; the bowels had been opened and there had been no sickness.

#### The Plague.

THE following telegram from Hong-kong from Governor Sir M. Nathan has been received at the Colonial Office:—"Seventeen cases of bubonic plague, 17 deaths, for week ended July 30th."

Oxford: Doctors at St. Aloysius.

ON Tuesday, July 26th, a special service was held in this church for the benefit of Catholic doctors attending the meeting of the British Medical Association. Some twenty or thirty medical men were present, including the President of the Irish College of Surgeons, who wore his robes. During the Mass, the choir boys, assisted by the young ladies from St. Ursula's Convent, sang very tastefully an appropriate selection of hymns. Father Arthur Day, S.J., delivered a short discourse, basing his remarks on the text of St. Paul: "Knowledge puffeth up: charity edifies." The dignity of the medical profession, as distinguished from that of the veterinary surgeon, rests on the admission of the immortality of the human soul. A materialist doctor must often in kindness hesitate to prolong human misery. Science is very necessary to surgeon and physician, but without deep religious belief neither can rise to the full nobility of his vocation. Learning alone is apt to inflate; animated with supernatural charity it becomes a powerful engine for good; and the Christian doctor almost an apostle.—*Tablet*.

WEDNESDAY, AUGUST 10, 1904.

### THE CHLOROFORM COMMITTEE REPORT.

THE British Medical Association do well in employing some of their resources for the furtherance of general scientific knowledge, and there is certainly no question that they could undertake to investigate with more hope of practical benefit than that of the dosage of chloroform. A Committee was appointed three years ago to examine the subject from different points of view, and their third annual report has just been issued. The previous researches of various observers on the action of chloroform have produced varying results, and whilst week after week reports of deaths from chloroform anaesthesia continue to come in, the profession cannot but feel their position in the matter to be an invidious one. Although the employment of ether and some of the newer bodies has rendered the use of chloroform less generally needful, it must nevertheless be borne in mind that not a few deaths occur under ether, while none of the new anaesthetics is absolutely safe. There remain a number of cases in which chloroform is still indispensable, and from the patient's point of view it is by far the pleasantest anaesthetic to take. For a long time past the comment has been made in various quarters that whilst the dosage of drugs is rigorously respected and enforced by medical men, yet when they deal with a highly dangerous medication, such as chloroform vapour, they administer an unmeasured quantity to the patient. This comment is not without its force. The only reply that can be made to it is that we are still ignorant of the quantity, or rather the percentage, that can be safely given. The fatal dose, indeed, is usually small. Several instruments have been devised from time to time by which the amount of chloroform administered can be measured, and the weighing of definite quantities of air and chloroform vapour be placed under the control of the operator.

Of these, Krohne's apparatus was the first, and demonstrated the extremely small quantity of chloroform vapour that, judiciously administered, can induce sound anæsthesia. Mr. Vernon Harcourt, F.R.S., a member of the British Medical Association Committee, has, however, devised a more accurate apparatus than any that have yet been put forward, and during the past year he has improved on his original pattern by introducing into it a carefully graduated conical bottle to hold the chloroform. By this means he is able to compensate, by an increased superficial area, for the diminution in the evaporation that results from the sinking of the chloroform in the bottle as it passes into vapour, and throughout the whole administration he can secure that almost exactly the same percentage reaches the patient with the inspired air. Another advantage of his method is that the rate and depth of respiration have hardly any appreciable effect on the actual quantity of chloroform inhaled, as in rapid respiration, although more air passes over the chloroform, it takes up less of the anæsthetic, whilst in slow, deep breathing the opposite is the case. It remains to be shown that chloroform administration will be rendered safer by the employment of graduating apparatus, the use of which, we believe, has not been unattended with fatal results. Side by side with the evolution of Mr. Vernon Harcourt's apparatus Professor Sherington and Miss Sowton have been pursuing a series of investigations into the action of chloroform on the isolated mammalian heart. The report of their work deals with experiments in perfusing the heart with small doses of chloroform in various solutions, and contrasting the effects thus produced with those wrought by similar doses exhibited in blood. Comparing the action on the heart of chloroform in saline solution with the action of chloroform in blood they found that the depressant effect of the latter was only one-twelfth that produced by the chloroform in saline solution, and also that when the quantity of chloroform was increased permanent damage to the cardiac muscle resulted much earlier when the anæsthetic was exhibited in saline solution than when exhibited in blood. Very interesting to compare with these conclusions are those arrived at by Mr. Byles, Mr. Harcourt, and Sir Victor Horsley, who undertook the work of estimating the effect of chloroform on the blood itself. Briefly summed up, their conclusions are that blood has a specific power of retaining chloroform, and that it is in the corpuscles, not in the plasma, that this ability resides, but that it is necessary for the corpuscles to remain intact if they are to keep this power. The amount of chloroform retained by the corpuscles was about 20 per cent., and thus it is obvious that the anæsthetic must have far-reaching effects on all the fixed tissues. Perhaps, however, the most important of the whole series was the closing experiment on a dog, anæsthetised by means of Mr. Harcourt's inhaler, from which quantities of blood were withdrawn at intervals, whilst the amount of chloroform was gradually increased

to the lethal point. Without going into all the details, it may be said that the quantity of chloroform in the blood at the time of death was almost exactly twice that found in the blood at the moment that anæsthesia was complete. We hope that this experiment and similar ones on other animals will be repeated, for it shows how small a margin exists between safety and danger. Dogs are notoriously susceptible to chloroform poisoning, and results obtained from experiments on them by no means apply equally to man, but anything that can throw light on the limits of safe chloroform administration is greatly to be welcomed. We trust, therefore, that the Committee will be able to pursue its labours for several years, as it can hardly be expected that the full facts will be established without a long period of hard work. If in the end the Committee are able to demonstrate how chloroform fatalities can be avoided, they will earn the gratitude of all their colleagues.

#### THE LORD CHANCELLOR AND THE MEDICAL PROFESSION.

OUR readers will remember that more than once during the past year or two we have had to comment on the attitude one of the London coroners has seen fit to adopt toward the general practitioners in his district, and the manner in which he is in the habit of exercising his public duties. As the facts must be already known to our readers, it is sufficient to recall that it is the custom of Mr. Troutbeck, the coroner in question, in conducting inquests, to ignore as far as possible the evidence of practitioners who had attended the deceased during life, or who had been called in immediately after death, and, further, whenever a *post-mortem* examination has been thought necessary, its conduct has been committed to one individual practitioner who has no claim to be considered a pathological expert. In many cases where valuable clinical evidence could have been brought forward, it has not been obtained, and verdicts have been returned on evidence obviously incomplete and insufficient. It is more than twelve months since, having failed to obtain any satisfaction from Mr. Troutbeck himself, four well-known medical societies—the British Medical Association, the South-West London Medical Society, the Medical Defence Union, and the London and Counties' Medical Protection Society—united in sending a joint deputation to the Lord Chancellor to draw his attention to the manner in which Mr. Troutbeck exercises his magisterial functions. They presented a terse memorandum embodying their views, and supported it by reference to several specific cases. This memorandum was then submitted by the Lord Chancellor to Mr. Troutbeck, and a copy of his observations thereon was transmitted to the Medical Societies, but no expression of the Lord Chancellor's opinion was given. The medical societies then formulated a detailed criticism on Mr. Troutbeck's observations, and sent it to the Lord Chancellor, receiving in

return a formal acknowledgment from his secretary. During the past twelve months his Lordship's attention has further been called to several cases as they occurred, in which Mr. Troutbeck either neglected material evidence, or went out of his way to attack medical men who had not been summoned to attend. Up to the present, however, the Lord Chancellor has refrained from committing himself on any of the points put before him. His Lordship should remember that high as is the dignity appertaining to the office he holds, that dignity only belongs to himself in so far as he fulfils the duties of his office. He is, like many humbler persons, as far as the performance of his public duties go, a servant of the State, and one of the most important of these duties is the supervision of the performance of their functions by the magistrates of the land. In the present instance various charges have been laid against one of these magistrates, the Coroner for Westminster, and his defence has been heard, but both complainant and defendant are still, after twelve months, waiting for a decision. Under the circumstances the only course open to the Medical Societies is the one they have taken, to publish the entire correspondence. The British Medical Association, however, has advanced matters by furnishing the Lord Chancellor with a carefully drawn statement of proof of all charges made against Mr. Troutbeck, together with a distinctive analysis of that gentleman's defence and counter-charges.

#### THE IRISH POOR-LAW MEDICAL SERVICE AND ITS OLD FRIEND "THE MEDICAL PRESS AND CIRCULAR."

A REMARKABLE letter appears in the columns of our contemporary the *Journal of the Irish Medical Association*, from the pen of Surgeon-General Evatt, on the subject of the organisation of the Irish Medical Association. Surgeon-General Evatt has recently visited Ireland as special commissioner of the British Medical Association, and has embodied the result of the information he acquired there in the form of a very long and elaborate report. This report we noticed on its appearance, when we had the greatest pleasure in drawing attention to its many good points, and, we may say, in also refraining from excessive criticism of its weak ones. Perhaps its most curious point was the utter failure to recognise that the majority of the matters to which it called attention in the condition of the Irish Poor-law Medical Service had been already emphasised and brought before the public time after time in the columns of THE MEDICAL PRESS AND CIRCULAR, and that it was to the insistence of this journal that much of the light of publicity which has fallen on Irish Poor-law matters in the last twenty years was due. In short, to judge from Surgeon-General Evatt's report it would appear that no journal other than the organ of the British Medical Association had ever worked for the betterment of the Irish Poor-law Medical Service. We did not at the time draw attention to this curious omission. Surgeon-

General Evatt had been sent over by another journal, and was for the time being its servant, and why should he see good in the work accomplished by a rival even though that work was spread over some half century, and that the disdain of his employers for mere Irish matters during that time was great? His recent letter, to which we now refer, cannot, however, be allowed to pass, in that not content with the mere ignoring of the existence of THE MEDICAL PRESS AND CIRCULAR, it proceeds to make serious mis-statements. We are quite willing to believe that these are the result of sheer ignorance of the facts of the case, but, even if that excuse is made for them, they require correction. "In Ireland," says Surgeon-General Evatt, "when a doctor wants a *locum tenens*, there is now, so far as I am aware, no organised centre to which he can apply by telegraph, &c.," and then he proceeds to recommend that such an office should be established. If Surgeon-General Evatt had not ignored the existence of a journal which is still older than the one he represented, and whose work for the improvement of, and whose knowledge, of the Poor-law Service is and has been immeasurably greater, he would in the course of his visit to Ireland have discovered that such an office has been in existence for many years, a fact that is well known. Again, Surgeon-General Evatt by implication suggests that there is no "Students' Number" published to give the Irish medical student full information, and to warn him of the drawbacks of Irish medical life." We all know what English ignorance of Irish conditions of life is, and what have been its fruits in the past, but, while such ignorance can be excused amongst those who remain at home, it can scarcely be excused amongst those who go abroad to seek information and who consider they have found it. Will Surgeon-General Evatt consult the Students' Numbers of this journal? will he read the advice to the young student that they have contained now for many years? and will he write and inform us whether he still considers that another Irish Students' Number is required? Will he then cast his eye over previous issues of this journal and its special Irish Poor-law Supplement, and will he tell us what he expects to gain by creating imitations? Surgeon-General Evatt hints that a misfortune of Irish medical life is redundancy and want of coalescence, and yet he advocates the duplication of everything that is now done by THE MEDICAL PRESS AND CIRCULAR. Perhaps if he were to go a little more behind the scenes he would learn that all the resources of this journal had been offered to the Irish Medical Association for the special purpose of avoiding duplication, and of furthering the interests of the Poor-law Service; he would thus understand how easy a thing it would be for the Irish Medical Association to make itself a more effective organisation, if it pleased to do so.

THE address on Surgery at the Vancouver meeting of the Canadian Medical Association will be delivered by Mr. Mayo Robson.

## Notes on Current Topics.

### A New Method of Testing the Heart.

A NEW method of testing the functioning power of the heart has been lately presented to the Verein für innere Medizin, in Berlin, by a M. Katzenstein. The information which it affords is said to be of special value in cases in which the heart is about to be subjected to a severe strain, as in certain surgical procedures, and as it is comparatively easy of performance it is worthy of attention. The procedure is based on the observations made on animals to the effect that the ligature of large vessels results in an increased cardiac activity, characterised by a rise in the blood pressure without any change in the pulse-rate. To apply the test, the patient is placed in a recumbent position and, when quiet, the pulse-rate and blood pressure are determined. Compression of both femoral arteries is then made and kept up for from two to five minutes, and then the changes in the blood pressure and pulse-rate are noted. If the heart is acting normally, the pressure causes a rise in the column of mercury of from five to fifteen millimetres, while the pulse-rate remains the same, or is slightly lessened. If the heart is hypertrophied, a rise of forty millimetres occurs, and the pulse-rate remains the same, or is slightly increased. Slight cardiac insufficiency is accompanied by increased pressure, the pulse-rate remaining unchanged or increased. Marked cardiac insufficiency is accompanied by a lowering in the pressure and an increase in the pulse-rate. These results are said to be very constant and trustworthy, and only to be affected by excitement or nervousness on the part of the patient.

### The Position of Gynæcology.

WE are pleased to see that Dr. Haultain, of Edinburgh, has drawn attention in the columns of the *British Medical Journal* to the extraordinary arrangement by which a discussion on hysterectomy came before the Section of Surgery at the recent meeting of the British Medical Association at Oxford. As our readers know, we had already called attention to the anomaly which brought a purely gynæcological subject before the Section of Surgery, and we trust that Dr. Haultain's letter will be a forerunner of further protests. He had expressed the hope that even at the last moment the discussion might be allocated to its proper place, but this was not done. An effort should now be made to determine who is responsible for the arrangements, and how it came about that this slight was offered to the Section of Obstetrics and Gynæcology. If a satisfactory answer is not obtained from the Council of the Association, and an undertaking given that at future meetings gynæcological subjects will be referred to the Gynæcological Section, it would be well for gynæcologists to consider if it is worth their while to support the meetings of the Association.

### Degenerates Again.

DR. F. J. SMITH, who read a paper on "Criminal Responsibility of Homicidal and Dangerous Lunatics" in the Forensic Medicine Section of the British Medical Association, is evidently what would be called in the political jargon of the day, a "whole-hogger." He thinks that we are far too humane to our lunatics, and he would have them destroyed, not by judicial hanging, but by the use of a lethal chamber. Few people will doubt that this is the rational method of dealing with individuals who are not only useless but dangerous. The man Prince, who created such a painful sensation by stabbing the actor, Mr. William Terriss, and was committed to Broadmoor. "during His Majesty's pleasure," signalled his sojourn there by perpetrating a murderous assault on his attendant. What use can it be to a community to preserve a depraved creature of this kind, whose existence consists in playing billiards and, when opportunity offers, killing a useful citizen? The only reply that can be given is that the trend of public feeling is all in the direction of humanitarianism—often mistaken—and that humanitarianism, like religion, is not confined within the bounds of strict ratiocination. Dr. Smith, then, follows Dr. Rentoul in advocating the sterilisation of lunatics, alcoholics, and the victims of other drug habits. Here again it is impossible to argue that his proposals are not eminently sane, but the favour that they are likely to meet with was evidenced by the disposition of his audience at the meeting, where they were generally described as revolutionary and impracticable. Difficult as the solution of these questions is in the present temper of society, it is well that they should be kept to the front, for the condition that allows propagation from the loins of criminals and lunatics of broods of tainted offspring discloses a weakness fatal to its ultimate success.

### Identification.

THE case of Mr. Adolf Beck that has lately been before the public cannot conduce to the feeling of security that is the right of every self-respecting citizen. In 1896 this unfortunate gentleman was sentenced to seven years' penal servitude for a series of heartless frauds on women, and again this year he was arrested, tried, and convicted of similar offences. Fortunately, before sentence was passed, another man was arrested through the exertions of a Mr. Glenville. On further inquiry enough evidence was accumulated to justify an immediate appeal to the Home Secretary for a free pardon for Mr. Beck, and this was granted with commendable promptitude. The prisoner, who has passed under various aliases, somewhat resembled Mr. Beck in appearance, and their handwritings were similar, but the astonishing fact remains that no less than fifteen different women identified Mr. Beck as the man who defrauded them, ten at his first trial and five at his second. In the face of such evidence it is hardly surprising that a conviction followed

in both cases, and it is difficult to attach any blame to the police authorities under the circumstances. In the best regulated States justice must occasionally be led astray; happily in this country its miscarriages are few. Mistakes in identification, when the identification rests in the hands of the police, should, however, be practically impossible at the present day. The wonderful accuracy of M. Bertillon's methods of measuring and classifying features is beginning to be recognised over here, whilst in France all detectives are regularly trained in his system. Besides identification by the pattern of the whorls of the thumb, M. Bertillon has a system of describing the characters of the leading features in a few abbreviated words that is fully sufficient to instruct any detective as to the detailed appearance of a suspect. The combination of all these characteristics puts any reasonable chance of error out of court entirely. The feature on which most reliance is placed is the ear, which is perhaps the most generally neglected characteristic, but all the other points in the appearance, such as the size, inclination, and shape of the nose, the colour and shape of the eyes, and so on, are all included in these "word-portraits," as they are called. The old haphazard rules of thumb that used to govern the police in identification have been superseded by practical applications of the science of anthropometry; we can only hope that Scotland Yard is fully abreast of its latest developments, for accurate identification is the basis of all successful criminal procedure.

#### Execution by Electricity.

AN increasing number of people are to be found who object to capital punishment *in toto*, and it is not altogether unlikely that the lapse of another half century may find public opinion in this country generally opposed to executing criminals. Whether individuals are in favour of its retention or not, all are agreed that the process of destruction should be certain, instantaneous, and painless, although, curiously enough, the mental agony of the condemned man, who is allowed to wait for weeks in his cell after sentence has been passed, is seldom taken into account. The horror of anticipation under this set of circumstances must be immensely more distressing than even the most physically painful execution. The American method of destroying life by passing a strong electric current through the body of the victim was hailed as a great advance on the old-fashioned process of using the guillotine. At the time of the inauguration of electrocution there were reports of difficulties in securing instantaneous death in one or two cases, but the impression generally prevails that with greater experience these difficulties have been overcome, and that the condemned man passes from life to death with unerring certainty when the current is switched on. This, however, is far from being the case. In May, and again in June of this year, instances of failure were reported, the criminal in the former case requiring five shocks, and in the latter three. Various

explanations were put forward to account for these horrible catastrophes, such as that the prisoner was thin, that his skin was thick and oily, or that he was a bad "conductor." The point has been raised in connection with these cases as to whether electrocution does always kill its subjects outright, or whether, as happens in lightning-stroke, the person is not sometimes the subject of profound shock from which resuscitation is possible. If so, the real cause of death in the criminals so treated is the knife of the pathologist who performs the post-mortem. The very idea is so revolting that it may well be hoped that our own antiquated method of execution may not be superseded by any other till at least absolute certainty of result is secured.

#### Dangers of the Drinking Cup.

THE possible perils of the Communion cup from the hygienic point of view have already been discussed in the medical and lay press, and we are glad to think that in many quarters attempts are now being made to cope with the difficulties that surround the introduction of any innovation, however beneficial, into religious observances. But there exists another danger from infection in the use of ordinary drinking cups by school children and others. In the case of the drinking fountains found in public parks and other places it is a wonder that more disease is not disseminated by this means, considering the filthy state of some of those who drink from them. The purity of the original water supply is often thus compromised by individuals who make improper use of the drinking cups, or who are themselves affected by some infectious disease of the face or lips. From the annual report of the Medical Officer of Health for Poplar, Dr. F. W. Alexander, it would appear that the drinking facilities for school children, especially during the present hot weather, are in much need of supervision. He rightly points out that the children themselves cannot be expected to take many precautions, especially those in the younger classes, and he approves of a method adopted by some schools in having the water in the schoolroom, where it is served out by the teachers as occasion requires. It is not a pleasant reflection to think that two or three cups do duty for a school of several hundred children, as has been observed, but now that public attention has been called to the whole question it is to be hoped that such primitive arrangements will no longer be in vogue. The enormous prevalence of impetigo of the face in certain quarters of the metropolis may possibly be accounted for through infection by means of the drinking cup.

#### Popular Medical Phraseology.

THE avoidance of technicalities in the witness-box or in writing a medical report destined for the consideration of the judicial mind is a necessity early impressed upon the student of forensic medicine. Plain Anglo-Saxon terms and phrases are to be preferred under such circumstances rather than the most accurate classical description. To the medically trained mind it appears, no doubt,

far more pathologically correct to describe the consequences of a blow upon the orbit as "an extravasation of blood accompanied with sub-conjunctival ecchymoses" than to express the same in the homely language of the man in the street. Nevertheless, the term "black-eye" and all that it implies is at once understood by those to whom a more scientific description would be absolutely unintelligible. Recent magisterial comments upon the subject of medical phraseology show how important it is not only for medical witnesses to describe symptoms in language that is "easily understood of the people," but also that the wording of medical certificates should be as simple as possible. In the case to which we refer, exception was taken to the use of the word "epistaxis," from which a drunken man was certified to be suffering. The term is certainly more impressive than its English equivalent, but it does not, unfortunately, find a place in police-court parlance. It so happens that this symptom is equally well defined by both the popular and the scientific designation, but there are many other instances in which the use of the Latin or Greek name is infinitely preferable, either on the grounds of propriety or, more commonly, because much wearisome circumlocution is thereby avoided. There are times and places, however, when only one of the two modes of expression is permissible.

#### Milk Supplies.

WE are glad to see more interest being taken, both inside and outside the medical profession, in the all-important matter of town milk-supplies. The subject has been given considerable space in the "dailies," and has formed a topic of discussion at the various summer medical gatherings. Out of the attention thus directed to it, it is sincerely to be hoped that practical schemes will arise to place the whole matter on a satisfactory footing. People have a touching faith nowadays in the power of the legislature to remedy all their evils, but they might well realise that, ready to their own hands, lie many methods far more speedy and far more efficacious. An example of what may be done with regard to improving the milk supply has lately been given by the citizens of New York, who found that, in spite of all the regulations and inspections of the Departments of Health, the milk that reached the houses was foul with dirt and bacteria. A Milk Commission, made up of physicians from the County Medical Society, was formed to offer the dairymen and milk dealers, first, free instruction in the principles of producing clean milk, and secondly, a public guarantee if their conditions were complied with. The practical effect of this guarantee amounted to a condemnation of all non-guaranteed milk, a fact which people soon discovered for themselves. A bacteriologist, Dr. Belcher, was appointed to visit the farms, instruct the farmers, suggest alterations in their premises and methods, and to test the milk. Needless to say, he found a great deal of instruction needed, for some of the farms were as filthy and badly kept as, let us say,

our own. Now that matters are in working order, the milk is regularly analysed, and the conditions of the farms kept under the eyes of an inspector. The milk is sold in two classes, "certified milk," which is guaranteed to have conformed to very stringent regulations, and is therefore rather dearer, and "inspected milk," which is bought with an assurance of having been produced under conditions of strict cleanliness. A self-helping plan of this kind is likely to work well, and we commend the idea to sanitarians on this "side."

#### Newspaper Medical Discovery.

THE correspondent of a leading London newspaper last week telegraphed the news of what he evidently regarded as a marvellous discovery—namely, the cure of some forms of idiocy by thyroid gland. Needless to say, the cure of cretinism by that drug has been well known to medical science for years past. The discovery of the marvellous action of thyroid gland was made by English observers, and is one of which our countrymen may be justly proud. It is somewhat amusing, therefore, to find a presumably well-informed London journal gravely announcing that a Vienna physician has succeeded in bringing cretinism within the category of curable diseases. Following the "bad form" which characterises modern lay journalism in these matters, the correspondent proceeds to publish details of cases thus treated. The incident appears to partake of the ineradicable modern leaning towards things "made in Germany." Surely, it would be more in accord with the imperialistic sense of pride, of which the journal quoted is a strong advocate, were honour given to English medical men where it is due instead of to belated Continental imitators. Why should not a wealthy London newspaper submit medical and scientific stuff to a qualified medical sub-editor?

#### Hospital Amalgamation.

AT a time when the rivalry of the medical charities has well-nigh reached a breaking strain, it is comforting to find two large institutions of the kind coming to a friendly amalgamation. Manchester requires an immense public medical service, owing to the large industrial population. The Victoria University of the city found that the practical requirements for instruction of midwifery were not adequately provided for. The University authorities, therefore, negotiated with the management of two large hospitals, St. Mary's and the Southern, with the result that amalgamation has been resolved upon, subject to the approval of the governors. The newly formed hospital, to be called St. Mary's, will be devoted exclusively to maternity cases so far as the wards are concerned, but it is proposed to establish an out-patient department for diseases of women and children. The principal advantage of the amalgamation is that it allows the provision of a maternity hospital and a training institution in midwifery such as hitherto have not existed. When the amalgamation of the two hospitals is completed

there will be 225 beds available for instruction in midwifery and the diseases of women and children. There will also be a school for the education of medical students, midwives, and midwifery nurses. Another advantage is that all danger of overlapping will be removed, and that the sick poor, for whom the institutions primarily exist, will be further benefited. Thus equipped, the teaching of midwifery in Manchester should be second to none in the United Kingdom. Londoners will note with regret that they possess no institution comparable with the proposed one at Manchester. Their hospitals are all in a condition of fierce rivalry, and any attempt at amalgamation is bitterly resented.

#### Millinery and Science.

THE excellent work of the Sanitary Congress at Glasgow was marked by a new feature, namely, a Woman's Health Conference, presided over by a great Scotch noblewoman. The departure is most praiseworthy, on most grounds, except, perhaps, that which appears to have commended itself chiefly to the attention of a local journal. The following amusing passage, culled from that source, would not be unworthy the attention of our esteemed friend and contemporary *Punch*. (We have suppressed names.) "Her Grace the D— of M—, who presided, wore a black gown, with a bolero trimmed with fine tucks, and relieved by a lace yoke, and by touches of white cord and lace. Her small toque was violet, with a cluster of white flowers. Lady H— G— wore pale grey with flecks of white, and a white silk and lace front and revers. She had a large hat of rose pink, with black plumes. Lady G— C— had a dark blue trottoir costume and bolero, with a hat trimmed with roses and Neapolitan violets. Lady P— was in brown cloth, faced with white, embroidered in brown and red, and wore a brown hat, with cream lace. Mrs. F— wore a pale grey gown, with a black hat, and Miss I— was in black. Mrs. M— wore black and white foulard, with a black velvet picture hat. Dr. E— P—'s blue gown of boucle cloth was smartly strapped with white, and a hat of blue straw with white silk was worn to match. Miss J. E. S— was in pale green, with strappings of fawn and green, Mrs. O— was in grey, with a black picture hat. Mrs. C— M— wore green, with cream lace. Mrs. B— F— was gowned in black, accordion-pleated, and trimmed with chiffon, with touches of rose pink. Black was also worn by Mrs. G—, with white facings, and a black crinoline hat."

#### The Examinations of the Central Midwives' Board.

THE action of the Central Midwives Board in appointing or deciding to appoint unqualified women to examine candidates for registration under the Midwives Act was brought before Parliament last week by Dr. Thompson in the form of a question to the Secretary of State. Mr. Akers Douglas replied that he did not think that the Board had taken such action, but even if they

had he had no power to interfere. In spite of this, we trust that members of Parliament will continue to bring the many unwarrantable proceedings of the Midwives' Board to the notice of the House, as sooner or later the amending Act will have to be passed, and it is well that the necessity for such an Act should be brought home to the Government and the members generally. The decision that the Board should be free to select anyone whom it chooses from, as Dr. Sinclair put it, "a highly gifted chambermaid" upwards, to examine the candidates for its diploma, was made in spite of the protests of several members. With the greatest respect for Dr. Cullingworth's high position in his profession, his action in supporting this decision appears to us to be most wrong, and to be prejudicial not alone to the interests of his own profession but to those of the women who shall present themselves for examination and of the public at large. When discussing the question of examinations, Miss Paget with charming naïveté, asked, "Surely for the first examination you will not be too strict? Surely medical examinations begin gently?" Miss Paget does well to make these requests; she in conjunction with other members of the Board have shut the door in the face of the highly qualified nurse, and have opened it to those who have attended twenty cases under the auspices of any general practitioner. Her protégées will undoubtedly require to be dealt with gently. It is, however, a poor consolation for those who had hoped for an improvement in the "Gamp" to learn that the Board entrusted with the carrying out of that improvement is compelled to deal gently with the incapable because it has seen fit to reject the competent. The nurses who would have presented themselves from the Irish maternity hospitals would not have required any favours from the examiners other than a fair examination. The first examination will be held in May, 1905, but whether it is to imitate the Board itself in its procedure and to partake, as Miss Paget apparently wishes, of the nature of a conversation, is not stated. Subsequently examinations will be held twice a year in London and the provinces simultaneously "or more frequently if necessary," in order, we understand, that the woman who fails at one examination may be able to present herself for re-examination at the earliest date possible.

#### Germ-Laden Railway Carriages.

FOR some years past the sanitary dangers of the unclean railway carriage have been before the public. British minds, however, like the poet's "mills of God," "grind slowly," although in the long run it must be admitted they grind "exceeding small." In other words, the next generation of our countrymen will most likely be provided with railway carriages built upon scientific sanitary methods and systematically cleansed. The rough surfaces and upholstery of our first and second-class carriages form an inviting rest and shelter for unwholesome germs. The scuffle of the foot along the carpet, or a pat on a cushion raises a cloud of

dust that might well make the stoutest sanitarian turn pale. Dust spells disease, especially in a railway carriage, and that form of "matter out of place" has been shown again and again to foster the microbes of consumption and other deadly maladies. In the bare unfurnished type of third-class carriage the chief lurking place of these evil germs appears to be on the rough floor. Why should not railway carriages be furnished throughout with smooth surfaces capable of thorough and efficient cleansing? The filthy condition of many a smoking carriage is nothing short of an outrage on society, which is obtaining some sort of first-standard School Board sanitary reform in other directions. Why should not railway carriages be systematically inspected by some central State authority?

#### PERSONAL.

ON the occasion of the King's recent visit to Liverpool, the loyal address from the University was read to His Majesty by Dr. A. W. Dale, the Vice-Chancellor of the University. Dr. Dale was presented to the King and Queen by the Earl of Derby.

THE Queen has consented to become patron of the Association for Promoting the Training and Supply of Midwives, the object of which is to organise and assist the training of women to act as midwives among the poor, and so meet the requirements of the new Act.

DR. F. F. CAIGER will deliver the Bradshaw Lecture of the London Royal College of Physicians on November 15th, instead of November 3rd, as previously announced.

DR. FREDERICK ROBERTS has been nominated Harveian Orator of the London Royal College of Physicians for 1905.

THE DUCHESS OF MONTROSE presided at a conference of women on hygiene at the 22nd Congress of the Sanitary Institute recently held at Glasgow.

THE Campbell Hospital for Infectious Diseases, presented to the public by Dr. Campbell, Convener of the County of Banff, was, on the 30th ult., formally opened by the Dowager Countess of Seafield.

DR. J. W. E. COLE has become a District Surgeon in the Administration of North-Eastern Rhodesia.

DR. J. M. L. BROWN, Medical Officer of Lagos, has resigned his appointment.

GEORGE MACKAY, M.D., F.R.C.S.Ed., of Edinburgh, has been elected President of the Caledonian Medical Society for the ensuing year.

MR. H. R. JOHNSTON, M.B.Dub., has received a handsome testimonial from the officers and staff of the Infirmary of St. Olave, Rotherhithe, on the occasion of his retirement from the medical superintendship of that institution, a post which he has held for eighteen years.

THE Senate of the University of Vienna has recently celebrated the retirement of Professor v. Vogl on attaining his 70th birthday.

DR. BENTLEY, of Kirkliston, Scotland, has been publicly presented with a horse and brougham for himself, and other articles for his wife and daughter, as a token of esteem from friends and patients.

DR. PRITCHARD, the London otologist, delivered

his valedictory address on August 1st, to the International Congress of Otolaryngology at Bordeaux, and cordially welcomed his successor, Dr. Moure, of Paris.

DR. J. F. PAYNE, the Harveian Librarian of the London Royal College of Physicians, will deliver the FitzPatrick Lectures in the College, on November 8th and 11th. The titles of the lectures will be "Gilbertus Anglicus and Medicine in the Anglo-Norman Period" and "Ricardus Anglicus, and the History of Anatomy in the Middle Ages."

DR. LESLIE has been selected by the Royal University Graduates' Association as a suitable person to be appointed to the vacancy on the Senate of the University caused by the death of Dr. William McKeown. Representations to that effect have been made to the Government, with whom the appointment rests, and they have promised to take them into consideration.

SIR JOHN W. MOORE, late President of the Royal College of Physicians of Ireland, received the honorary D.Sc. degree from the University of Oxford on the occasion of the recent meeting of the British Medical Association.

COLONEL F. HOWARD, Army Medical Service (retired), has been appointed President of a Medical Board to examine candidates for the Royal Military Academy and Royal Military College.

THE Fishmongers' Company have given £500 to King Edward's Hospital Fund, and twelve other smaller amounts to hospitals.

SIR RILEY LORD, when Mayor of Newcastle, succeeded in raising by public subscription £100,000 towards the new Infirmary. Lord Armstrong and Mr. John Hall, shipowner, each gave £100,000 to the same object. Sir Riley has now announced his intention to present a white marble statue of Queen Victoria, to be placed in front of the Newcastle Royal Infirmary.

DR. FREDERICK ROBERTS has been appointed Harveian Orator for 1905, on the nomination of the President of the Royal College of Physicians of London.

### British Medical Association.

SEVENTY-SECOND ANNUAL MEETING,  
OXFORD, 1904.

[THIRD ARTICLE.]

[BY OUR SPECIAL MEDICAL REPORTER.]

#### THE ANNUAL EXHIBITION.

THE annual display of surgical and scientific instruments, sanitary appliances, foods and food products, medical publications and other material pertaining to the realm of the healing art has for long been a particularly valuable feature of the great yearly gathering of British practitioners. There is need, however, that special precautions should be taken to maintain a high standard in the conduct of this periodic exhibition. We are strongly of opinion that the scientific rather than the trade spirit should be dominant in the selection and arrangement of the exhibits. Too often, it has appeared to us, exhibitors have adopted methods more likely to impress a gullible public than influence discriminating practitioners. We consider demonstrations should as far as possible replace mere verbal presentations. All mere vulgar forms of touting should be rigorously discountenanced. It would be well if greater care was taken in the selection of material exhibited; wines, tobacco, and goods not strictly medical or bearing directly on a practitioner's life and work, should be excluded. The catalogue might be made a much more valuable manual for reference if it contained illustrations and descriptions of new appliances. At present the contents are in great measure a mere enumeration of old or would-be favourites. This year's exhibition

reached a high level of excellence, and as far as we were able to see the exhibitors were generally judicious and courteous in urging the claims of their respective preparations. In most instances, the various stalls were arranged to attract professional notice, but one well-known extract of meat company, trading under distinguished directors, adopted a method of attracting public inspection, which, to say the least, was not Oxonian in its scientific modesty.

Mr. Guy Elliston, as manager, has accomplished a particularly difficult task with much tact and judgment. In the future we shall expect even greater advantages to accrue from the new policy of directing and controlling the annual exhibition from headquarters.

#### SURGICAL INSTRUMENTS.

A number of well-known makers were represented. Messrs. Down Bros. showed many new models. Messrs. S. Maw, Son and Sons exhibited a good selection of instruments. John J. Griffin and Sons demonstrated the advantages of the new Harcourt Chloroform Inhaler. John Weiss and Son displayed their products; and Mayer and Meltzer had a good collection of laryngological, aural and other instruments. Messrs. Allen and Hanbury had a very extensive display, and J. Gardner and Son, F. Davidson and Co., Brady and Martin, and the Holborn Surgical Instrument Co. all had interesting exhibits. Arnold and Sons exhibited a number of particularly valuable new inventions.

#### HOSPITAL EQUIPMENT.

The exhibition was particularly rich in material connected with hospital construction and equipment. Messrs. Doulton and Co. showed lavatory and bath fittings; Geo. Gale and Sons showed various forms of their "Lawson Tait" bedsteads and other hospital furniture; the Marshall Sanitary Mattress Co. exhibited mattresses and a convenient "Handy-Cosy" folding bed; the Longford Wire Co. had useful forms of bed fittings; W. H. Bailey and Son showed various novelties and useful types of operation tables; Messrs. Allen and Hanbury had aseptic hospital furniture in phosphor bronze, German silver, and enamelled steel; Messrs. Philip Harris and Co., of Birmingham, also had a good display. Indeed it would seem now that all the best instrument makers and many furnishing firms make the matter of hospital equipment a leading feature; and certainly, judging by the admirable display, at Oxford, the modern has innumerable advantages over the ancient equipment of a few years ago. Frank A. Rogers had a well-arranged exhibit of his sprays and other convenient pharmaceutical preparations. G. H. Neal had an extensive display of clinical thermometers, including the useful "Repello." Aseptic and antiseptic dressings were shown by such firms as Petol, Ltd., Cuxson, Gerrard and Co., Peat Products Co., and the Sanitary Wood-Wool Co. The Berkefeld Filter Co. demonstrated the use of their different forms of filter.

#### ELECTRICAL APPARATUS.

Excellent exhibits of X-ray apparatus, high frequency appliances, and medical electrical equipment were made by Harry W. Cox, the Marconi Wireless Telegraph Co., the Medical Supply Association, and Isenthal and Co. Various models of the Hodgkinson electro-neurotome were demonstrated.

The Dowsing Radiant Heat and Light Co. had an elaborate exhibit of arrangements illustrating their system of treating certain diseases by hot air, the Finsen light, &c.

#### DRUGS AND PHARMACEUTICAL PREPARATIONS.

Many well-known houses made excellent displays of old-established preparations. A few new synthetical bodies were exhibited, but the novelties were rather in the direction of elegance and convenience of form than actual originality in composition.

Burgoyne, Burbidges and Co., showed a number of the useful Heyden pharmaceutical products, including acöine, cresotal, salocrool, and xeroform; C. de Trey and Co. exhibited the new anæsthetic somnoforme; Wyleys, of Coventry, had an attractive show of their

elegant elixirs, syrups, pastilles and other well-known preparations; Hedley and Co. reminded us of the use of ethyl chloride as an anæsthetic; Oppenheimer, Son and Co. showed that "palatinoids" may be employed as a serviceable form of administering many of the new drugs; Parke, Davis and Co. exhibited a collection of their standardised drugs, an excellent collection of sera, and a series of lantern slides illustrating biological and pharmacological processes now employed in the preparation of therapeutic material; the Bayer Co. displayed many synthetic compounds, including the serviceable veronal, somatoc, citarin, aspirin, and heroin; Mr. W. Martindale displayed many of his elegant pharmaceutical preparations, and reminded the profession that a new edition of his invaluable "Extra Pharmacopœia" had just been issued; the Charles H. Phillips Chemical Co. called attention to their Milk of Magnesia and other American preparations; A. and M. Zimmerman had a collection of Schering's and other Continental manufacturers' well-known products; Fairchild Brothers and Foster showed their various digestive products; Jeyes' Sanitary Compounds Co. drew attention to Cyllin, their new name of an old favourite disinfectant (creolin); Angier's Emulsion was also prominently displayed; Duncan, Flockhart and Co. had a good exhibit of anæsthetics, soaps, compressed tablets, and other special preparations; Arthur and Co. showed various cosmetics and other novelties; C. J. Hewlett and Son were well represented by a good display of their well-known mixtures and some new synthetic remedies; Andrus and Andrus exhibited formolyptol and hæmaboloids; H. and T. Kirby and Co. advertised the merits of Purgen; Brady and Martin, of Newcastle-upon-Tyne, also made a good display of many elegant preparations. The Denver Chemical Manufacturing Company has an extensive display of Antiphlogistine a silicate compound which is coming into extensive use as a new form of poultice or compress in swollen joints, for which it forms a firm but flexible support. It has also proved its utility when employed in deep-seated inflammations, and seems likely to attain therapeutic eminence; and the Ferroleum Co. showed their much-lauded emulsion of cod-liver oil, iron and phosphorus.

#### FOODS, DRINKS, AND FOOD PRODUCTS.

As usual, these found place in rich abundance, and oftentimes occupied positions altogether beyond their merits. It is certainly desirable that the exaggerated claims made by the manufacturers of many milk, food and meat preparations should not appear to receive endorsement by the profession. Much discernment and discrimination is necessary in the selection of preparations coming under this head, and we are not convinced that sufficient sifting has been employed in the admission of some to this year's "show."

Liebig's Extract of Meat Co. made a somewhat unusual display of Oxo considering the character of the audience appealed to; the International Plasmon Co. exhibited various preparations of Plasmon; the Maltico Food Co. showed their different specialities; Callard and Co. had a good display of starchless foods; the Shredded Wheat Co. demonstrated the delights of their biscuits; Reynold's Wheatmeal Brown Bread advertised its digestive distinction; the Cheltine specialities were also well to the fore; Cosenza and Co. reminded visitors of the convenience and comfort of Maggi's Consommé; the Galak dry milk claimed to be a veritable food of high excellence; M. Hoff showed his well-known malt extract; Mellin's valuable dietetic preparations were prominent; Cadbury Bros., of Bourneville, showed much tasty chocolate; Irven and Co. exhibited their Klonat brand of dried milk; Armour and Co. had an elaborate display of their animal products, digestive ferments and glandular extracts in tablet and powder form; the Aylesbury Dairy Co. showed samples of their well-known humanised milks; Nestlé reminded visitors of his claims for Milo food and the Viking unsweetened

milk; Brand and Co. exhibited their juices and jellies and other specialities for invalids; Virol and Bovril also had prominent exhibits; Albene, a vegetable fat, was shown by Broomfield and Co.; the Manhu diabetic foods were also exhibited, and Van Abbott and Sons showed their gluten bread and special foods for obesity, diabetes, and various dyspeptic states.

The claims of "waters" seems to be limitless. C. Oppel and Co. displayed Friedrichshall; Ingram and Royle showed many natural mineral waters; Arabella water at least attracted by its name; Idris and Co. made an attractive grouping of their table waters and lime-juice preparations; the Apollinaris Co. demonstrated the purity of the source whence the Apollinaris water is derived, and the value of the now well-known aperient water Apenta; Alexander Riddle and Co., and Feltoe and Smith showed lime and lemon juice preparations; Camwal aerated waters were prominently displayed; Allsopps exhibited their lager beer; Stephen Smith and Co. advertised Hall's Wine; Coleman and Co. showed Wincarnis; and Keinheimer and Co. displayed their Nektar wines.

#### MEDICAL PUBLICATIONS.

We could wish that means could be found whereby all the recently published works could be brought together and conveniently grouped in the form of a temporary library. At the present time the display of medical literature is incomplete and inconvenient, and, we imagine, does little for the publisher, as evidenced by the absence of most of the leading houses, and still less for the serious student. The firms exhibiting this year were John Bale, Sons and Danielsson; Macmillan and Co., H. K. Lewis, Cassell and Co., John Wright and Co., J. B. Lippincott Company, and W. B. Saunders and Co.

#### MISCELLANEOUS.

It is impossible in the limited space at our disposal to indicate all the stands found in the annual exhibition. In addition to those already mentioned reference may, however, be made to various forms of orthopaedic apparatus and appliances for the lame, shown by the O'Connor Extension Company, N. Bletchley, Messrs. Salt and Sons, and F. Gustav Ernst.

W. and A. K. Johnson exhibited a series of diagrams on Hygiene. "Ronuk," Ltd., showed their well-known sanitary polishes for hospital floors. The Trading and Manufacturing Co., of Temple Bar House, demonstrated the advantages of their card index systems. The Cellular Clothing Co. exhibited their Aertex underclothing. The Boroughs of Leamington, Harrogate, and Buxton drew attention to the value of their respective towns as desirable health resorts.

In conclusion, we would again congratulate all concerned in the preparation and conduct of this year's exhibition. We would, however, suggest that in future the usefulness of the catalogue might be increased if a subject index could be added in addition to that of exhibitors and advertisers.

### Special Correspondence.

[FROM OUR SPECIAL CORRESPONDENT.]

#### BELFAST.

**MEDICAL APPOINTMENTS IN BELFAST.**—Dr. W. M. Killen has been appointed attending surgeon to the Benn Ulster Eye, Ear, and Throat Hospital, in place of the late Dr. W. A. McKeown. In consequence of this appointment, Dr. Killen has given up general practice, and has resigned his post of medical attendant to the Royal Irish Constabulary. For this post there are said to be about twenty candidates, who are all hard at work bringing influence to bear on the police authorities. The appointment will be made in the course of the next few days. Another post rendered vacant by Dr. McKeown's death is that of lecturer on ophthalmology and otology at Queen's College. No appointment can be made till the session opens in October,

but it is understood that there will be at least four candidates for the post. The appointment rests in the hands of the College Council.

**HEALTH OF THE CITY OF BELFAST.**—The report of the Medical Officer of Health for 1903 has just appeared, but offers no novel points for comment, being the same hopelessly insufficient document as in past years, chiefly remarkable for its omissions. The number of cases of typhoid and simple continued fever notified fell from 1774 in 1902 to 1,432 in 1903, and the deaths from the same affections from 181 to 144. The rainfall increased from 37 inches to over 44, and probably the thorough flushing of the sewers had not a little to say to the decrease in these diseases. The deaths from phthisis and diseases of the respiratory organs were 2,675, the lowest since 1897. Considering the increase of population this shows considerable improvement, though the deaths from these largely preventable diseases are still fearfully numerous. Three pages of the report are devoted to a detailed history of fifteen cases of small-pox, which occurred in the last three months of 1903, which is rather ancient history now, as we have had an extensive outbreak since then. No maps of the city to show the incidence of various diseases are given, no mention is made of the refuse destructor or its working and we find no reference to the important subject of the inspection of food and seizure of unsound meat, &c. We commend these points to the careful attention of the new chairman of the Public Health Committee, Dr. King-Kerr, and to his medical colleagues on that committee, Dr. A. Browne and Dr. O'Neill.

**PROPOSED SANATORIUM FOR CONSUMPTIVES.**—The question of the proposed sanatorium was under discussion at the monthly meeting of the Belfast Corporation held last week, and some idea of the proposal was sketched by the chairman of the Public Health Committee. The estimated cost of building and furnishing is about £20,000, and it is to be of such a size that 300 to 400 patients can be passed through it each year, at a cost of £6,000, which will be paid by one penny in the pound on the rates. The Board of Guardians will send the more curable cases from the Union Infirmary, and will pay half the cost of maintenance. It is also proposed to take paying patients. Some thirty or forty sites have been offered to the Corporation, and at present these are being examined and plans being perfected, and the whole scheme will shortly be presented to the Corporation for final discussion and decision.

**THE SMALL-POX EPIDEMIC.**—There is a distinct falling off in the number of small-pox cases notified in the last month in Belfast. In the month ending July 16th, there were twelve cases, but none since. There has, however, been an outbreak in Armagh. Two cases were reported on August 3rd, and removed to the fever hospital, where one has since died, and four more cases were admitted the next day. The house in which the first case appeared had been used as a lodging-house for some of the extra police drafted into Armagh during the recent disturbances there, and it is feared that these men may have been exposed to the infection. A number of known "contacts" have been isolated.

### Correspondence.

[We do not hold ourselves responsible for the opinions of our correspondents].

#### THE DIMINISHING BIRTH-RATE.

To the Editor of THE MEDICAL PRESS AND CIRCULAR

SIR,—I am a country medical practitioner, and have read Dr. Walsh's able and philosophical articles with the deepest interest. With the greatest industry and economy I can provide for my rent, keep a horse and trap, and pay my way. My wife is a lady by birth, and accepts her share of household drudgery without complaint. We have one child a son, five years of age, whose schooling will soon have to be provided for, but I fear, unless things take a

considerable turn for the better, he will not have that public school training which has been a tradition in my family for generations. The position is this: Here is a struggling professional man just able to make both ends meet by the help of his wife, a refined lady who does the work of a general servant, and yet has to keep up appearances. What would happen if we went on multiplying children, as Dr. Taylor tells us it is our duty to do? Why, my wife would soon be dead, and the children motherless. How could I, deprived of their mother, hope to clothe, feed, and educate those children and send them out into the world with any chance of comfort and success? No. Give me the prudence of prevention rather than the selfish recklessness of over-production. A living neurasthenic is better than a wife in her grave.

I am, Sir, yours truly,  
A COUNTRY PRACTITIONER.

Bucks, August 8th, 1904.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—I do not wish to press any advantage, but on referring to the Parliamentary Report, I find that there is a very serious discrepancy between the actual facts and the figures given by Dr. Walsh which cannot be ignored.

From Table III, p. lxxxiii, of the 64th Annual Report of the Registrar-General, I take the following figures:—

		BIRTHS TO 1,000 LIVING.	
Total in England and Wales.		Legitimate.	Illegitimate.
In 1884	.... 33'6	.... 32'0	.... 1'6
In 1901	.... 28'5	.... 27'4	.... 1'1
Loss	.. 5'1	4'6	5

Dr. Walsh states in THE MEDICAL PRESS AND CIRCULAR for July 13th that the total birth-rate in 1884 stood at "31," and builds his main argument on this! I am sorry he has made this mistake, for it has given not only him and myself, but also a kind correspondent who has written to me on the subject, a lot of unnecessary trouble. The illegitimate births have diminished with the general diminishing, but are almost a negligible quantity.

I am, Sir, yours truly,  
JOHN W. TAYLOR.

22 Newhall Street, Birmingham.  
August 3rd, 1904.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—I am the wife of a curate, who, thanks to the inequalities of incomes in the Established Church, has, at the age of forty, to be thankful for his luck in securing an annual income of £250. On that sum I have to keep house, to feed, clothe, and educate two boys and one girl. That means I must myself do sewing, mending, housework, while the household is pinched and starved merely to ensure the necessities of life. What would have happened had my children been unrestricted—say, eight or ten, as Dr. Taylor says they should be? The prospect is appalling. I should have had to feed them on bread and onions, and turn them out into the world hopelessly handicapped in body and mind—that is to say, had I lived through the toil and worry and the physical drain of multiple child-bearing. Purity and high thinking and social culture do not pay for boots and frocks and food and housing. Why should I bring children into the world on the strength of social and intellectual qualifications that fail to furnish the decencies of life reasonably demanded by my husband's station in society? Does Dr. Taylor think I should have produced those additional children or not?

I am, Sir, yours truly,  
A POOR CURATE'S WIFE.

Manchester, August 6th, 1904.

#### PREVENTION OF PERINEAL RUPTURE.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.  
SIR,—This well-worn subject, on which you comment

in your last issue, *re* Dr. Laphorn Smith's treatment, should raise a smile. "A little nonsense now and then is relished by the best of men." Dr. Laphorn Smith evidently believes in "a stitch in time," but on the same principle every adult male should have the prostate gland removed so as to avoid the inevitable "hypertrophy," with all its accompanying troubles, later on in life.

The simple plan proposed by me years ago (and which I have never found to fail should I be called to the case *in time*) is simply drawing back the perineum forcibly *during* each pain. The late Dr. Parvin, of Philadelphia, alludes to it in his work, "Science and Art of Obstetrics," page 410, and I make bold to say it will be found the best preventive treatment (no anaesthetics required) of laceration of female perineum.

I am, Sir, yours truly,  
ALEXANDER DUKE.

#### PROPOSED STERILISATION OF CERTAIN DEGENERATES.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—In reviewing the above work, your reviewer attempts to give the impression that I advocate suicide as a means of checking degeneracy. I do not. Nature attempts to deal with insanity in this way, but her efforts are not successful. It is in this respect Nature requires our help—sterilisation. If any of your readers will refer to page 10 of the above, they will find the following:—"Keep everything alive. For, if to-morrow every degenerate were killed, but the causes of their being degenerate were unattended to, then as large a number of degenerates would take their place. There is no real cure so long as the causes remain ignored."

I am glad to see your reviewer denounce our present "Christian" custom of allowing "cured" lunatics to marry, or to return to conjugal relations.

I am, Sir, yours truly,  
ROBERT R. RENTOUL.

Liverpool.

#### SOME OF THE NEWER (?) METHODS OF OPENING AND CLOSING THE ABDOMEN.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Dr. Tweedy states in his letter, in reply to mine on above subject, rather dogmatically: "These so-called 'Bozemann plates' are placed at intervals [*italics mine*] across a wound." Dr. Bozemann states in his letter to me: "There is certainly no object in having a window through which to view the reparative process—the adhesion of the wound would go on just as well *in the dark*." From the tone of his letter I conclude Dr. Tweedy is not quite pleased that the plan to which he called attention and stated "(so far as he knew) was novel," is Nathan Bozemann's pure and simple, and perhaps it would not be too early for him to act on his own advice as regards a post-graduate course!

I am, Sir, yours truly,  
A. D.

London, W.

#### Obituary.

T. GILBART SMITH, M.D.DUB., M.A., F.R.C.P. LOND.

WITH much regret we announce the sudden death of Dr. T. Gilbert Smith, at Twerton, Devon, where he was taking a bicycling tour with his son by way of a summer holiday. Death was due to heart failure, and took place at the comparatively early age of 56. Deceased was for many years on the staff of the London Hospital, as assistant physician, and afterwards as physician. Among other appointments he held that of physician to the Royal Hospital for Diseases of the Chest. He was well known and popular as a teacher of sound as well as of brilliant qualities. Socially, his kind and genial disposition made him the centre of a large circle of friends both inside and outside his own profession. His medical education was

conducted at Dublin University, and at St. Bartholomew's. In 1871, he took the English diploma of M.R.C.S., and in 1885 the Fellowship of the same body. He became bachelor of medicine of Dublin University in 1869, and graduated M.D. T.C. in 1873. Dr. Gilbert Smith was a member of many learned societies, and made numerous contributions to medical literature. His death deprives the distinguished knot of Irishmen in London of a well-known and esteemed figure.

STAFF-SURGEON HENRY SCANLAN, M.B.,  
C.M., Univ. Glasgow.

WE regret to announce the death of Mr. Henry Scanlan, M.B., Staff Surgeon of the Royal Navy, retired, on the 31st ult., at the residence of his brother, Kerswell, Broadclyst, Devon, at the age of fifty-five. After taking the M.B. and C.M. Degree from the University of Glasgow in 1871, he entered the Navy as a Surgeon in March, 1872, and became a Staff Surgeon in March, 1884, serving with the Royal Marine Battalion at Suakim during the operations in the Eastern Soudan in 1884-5, for which he had the medal with clasp and the Khedive's bronze star. He was placed on the retired list in March, 1885.

### Literature.

#### PREVENTION OF DISEASE IN ARMIES. (a)

THE fact that this little volume has brought its author the Parkes Memorial Prize and Bronze Medal should give it a special interest at the outset, as it proves in the most conclusive way the high estimate which has been formed of its contents by those who are, presumably, among those who are best qualified to form an opinion on the subject. On this fact by itself we cordially congratulate the author and his publishers. Major Caldwell tells us in his preface that: "This little book has been written in the hope that what is, in the main, a record of sanitary experience in the field may possibly prove of some interest to those whose attention is particularly drawn to the physical well-being of the soldier on service." But the great merit of the volume, to over-read reviewers and journalists, is indicated in the next sentence: "I must apologise for the constant introduction of the personal element on the ground that I have endeavoured to formulate my own conclusions from my own experience, and to avoid the repetition of well-known matter." The way in which Major Caldwell has followed out the lines of the chart thus indicated would, in our opinion, have earned for him the merit of a foremost place in any series of contributors to the literature of scientific medicine. And, in the present instance, a glance at the title-page will show what excellent opportunities he has had for forming opinions based upon ripe experience, gathered in widely-separated regions of the earth's surface. The award of the Parkes Memorial Prize shows what the judges thought of the value of his opinions, and we heartily endorse their view of the sterling merit of his volume.

The contents are arranged in six chapters:—I.—Introduction. II.—Diseases of Soldiers in the Field. III.—Administrative Matters Affecting the Health of Troops in the Field. IV.—Sanitary Measures in the Field. V.—The Sanitary Organisation of a Field Force. VI.—General Conclusions and Recapitulation. The contents are of special interest at the present date, giving, as they do, so excellent a summary of sanitary and insanitary methods and experiences connected with the recent war in South Africa—accentuated, of course, by the increasing war and rumours of wars in the Far East at the present date. Strange recollections of infection are necessarily interspersed in the wide experience of Major Caldwell. The occurrence of

(a) "The Prevention of Disease in Armies in the Field." By Robert Caldwell, F.R.C.S., D.P.H., Major R.A.M.C. Member of the late War Office Committee on Field Sanitation in connection with the South African Campaign; late Member Sanitary Committee, Island of St. Helena; Senior Medical Officer, Zululand; Medical Officer in Charge of Isolation Hospital and District Laboratory, First Army Corps. London: Baillière, Tindall and Cox. 1904. Crown 8vo, pp. viii and 182, and 28 illustrations. Price 5s. net.

a case of ague in St. Helena is an instance. Endemic malaria is unknown in that island; and the patient had never in his life been exposed to possible mosquito contact, except on the occasion of his return from a visit to England. He then passed so "close to the land while near Cape Verde—so near that the passengers could plainly distinguish trees and human habitations." Shortly after landing in St. Helena he was seized with a severe attack of ague. . . . The only possible explanation, according to the theory of malarial contagion now established by scientific research, is that some of the mosquitoes were wafted on board from the tainted African coast. Of the excellent illustrations which accompany Major Caldwell's text we must specially point out—"Fig. 1. Scene near Summit of Drakensberg. The surroundings were typically healthy, and the water was of excellent quality, and drawn from rock springs. In spite of these advantages, enteric fever occurred (in a mild form) among the troops in the district." The explanation—the only possible one—is furnished on the next page: "The camp had been occupied for some months before the disease broke out, and although every possible sanitary precaution was most faithfully carried out, the avoidance of soil pollution was a matter of impossibility." We will make no further extracts, and close this notice of an admirable thesis by recommending its pages to the attention of all our readers.

#### MIDWIFERY FOR MIDWIVES. (a)

THE aspirant midwife is receiving more than her share of attention at the present time, and numerous indeed are the works submitted for her approval by authors, lay and medical. Dr. A. B. Calder's "Questions and Answers on Midwifery for Midwives" is a highly condensed synopsis of the information required by the candidate for the L.O.S. certificate. First we have brief anatomical details of the female reproductive apparatus, followed by a fairly full description of normal labour. In this connection we should like to know what practical bearing the following remark can have: "If ante-partum eliminations have been thoroughly aseptic, no douche will be required." Who can answer that question? And, failing an answer, is the douche to be given or not? Then we have definitions of the normal and abnormal child and the normal and abnormal labour, the author having overcome the difficulty experienced by the originators of the Midwives Bill in distinguishing between the two. Finally, model answers to questions, together with a selection of questions actually put. This little volume is a perfect epitome of what to do and what not to do in the lying-in room, and a candidate who had assimilated its contents even approximately would not fail to carry all before her. It is, in fact, a Liebig's Extract of obstetrical principles for midwives' and nurses' use.

#### SIR JAMES SAWYER ON INSOMNIA. (b)

SIR JAMES SAWYER has recently published an interesting collection of clinical lectures under the title of "Contributions to Practical Medicine," and the work before us comprises the first two chapters of those essays. Insomnia is a subject which always attracts a good deal of attention, although it cannot be regarded as a disease, and is simply a symptom of some underlying functional or organic disturbance. The author arranges the different clinical varieties into groups, which he calls respectively "psychic," "toxic," and "senile." A most interesting and graphic sketch is given of intrinsic insomnia as met with in general practice, the illustration employed being that of a young professional man without adequate means waiting for the advent of clients. Attention is directed to the causal association of a nervous temperament with this

(a) "Questions and Answers on Midwifery for Midwives." By A. B. Calder, M.B., M.R.C.S. Pp. 148. Price 1s. 6d. net. London: Baillière, Tindall and Cox.

(b) "Insomnia: its Causes and Cure." By Sir James Sawyer, M.D., F.R.C.S., Senior Consulting Physician to the Queen's Hospital, Birmingham.

form of insomnia and stress is laid on the importance of recognising and studying that individual peculiarity of physical organism by which the manner of acting, feeling, and thinking of every person is permanently affected. Under the head of the senile variety, it is pointed out that the broken and short sleep of many old persons is the result mainly of degeneration of the smaller cerebral arteries. This is the explanation of the exaggerated appreciation of the merits and value of early rising so often observed as age advances. In the second chapter, which is devoted to the "Cure of Insomnia," much valuable advice is given respecting the routine employment of hypnotics. "Prescribe hypnotics only in exceptional cases." "Never allow a patient to dose himself with hypnotics." This is good advice, and there are many equally useful hints in this admirable work. We find a reference to tar-water and to the writings of the Rt. Rev. Dr. George Berkeley, Lord Bishop of Cloyne. What we miss, however, is some reference to the frequent toxic action of sulphonal on the kidneys when taken in even comparatively small doses. There have been so many deaths from this cause that it is difficult to ignore the danger. Sir James Sawyer has written a most interesting, and, if we may venture to say so, amusing book, containing much good, sound, practical advice, which will be found useful to everyone in practice.

#### THE THERAPEUTICS OF MINERAL SPRINGS AND CLIMATES. (2)

DR. BURNEY YEO has produced an admirable work on mineral springs and climates founded on many years' practical experience revised and brought thoroughly up to date as the result of a long self-imposed winter holiday. It is not every physician in active practice who can afford the necessary time to visit the various places he describes, and too often the knowledge is obtained second hand, and is little more than an abstract of the information given in guide-books and pamphlets published locally. There is a distinct demand for a good and thoroughly trustworthy work of this description, for it appeals not only to medical men, but to the vast army of valetudinarians who spend the greater part of the year travelling from one health resort to another. "Where to go" is a common topic of conversation, and the practitioner who is not thoroughly acquainted with the subject finds himself at a disadvantage. Macpherson's "Baths and Wells of Europe" is an excellent work, but it is out of date, and requires revision, and the same may be said of the "Mineral Waters and Health Resorts of Europe," by Sir Hermann Weber and Dr. F. Parkes Weber. The "Climates and Baths of Great Britain," published by a Committee of the Royal Medical and Chirurgical Society of London, although good in intention, failed to attract the notice which from the reputation of the contributors it deserved. Dr. Yeo's book, which is in the main arranged alphabetically, deals not only with climates and climatic resorts, but with mineral springs. His introductory chapter on the nature, composition, and classification of waters is practical and to the point. A large proportion of our medicinal waters come from Germany and Austria, and the number in Great Britain is, unfortunately, comparatively small. The subject of table waters has of late occupied much attention, and the author treats fully of Apollinaris, St. Galmier, and the seltzers. He, however, as far as we have been able to discover, omits all mention of Source Perrier from Vergèze, in the department of Gard, France, a water now extensively used on the Continent, and universally drunk on the Riviera. Source Perrier is a first-rate table water; it is absolutely pure and free from contamination, and is strongly effervescing with its own natural carbonic acid gas. This is but a small omission, and will doubtless be remedied in future editions. Among the bitter or purgative waters Apenta comes in for a large share of attention, but, curiously enough, Hunyadi Janos is dismissed in four

lines of small type, and *Æsculap* is equally summarily dealt with. This is to be regretted, for it gives one the idea of want of proportion. We have looked for some information on *Arabella Water* from Kelenföld, in Hungary, but do not find it mentioned. A good account is given of the mode of treatment adopted at Harrogate, and justice is done to the improvements recently effected at this popular English health resort. Going further afield, we find an excellent description of *Hammam R'Irha*, in Algiers, but surely the place from which it is most conveniently reached is *Bou Medfa*, and not "Bon Medfa."

#### SAUNDERS' YEAR-BOOK. (4)

THERE is no other book in the English tongue which exactly corresponds in scope and aim with "Saunders' Year-Book of Medicine and Surgery," which has recently reached us. It is described on the title-page as a "yearly digest of scientific opinion," and it is only just to say that it is something more than a mere abstract of articles that have appeared during the year. The general editor, Dr. George Gould, has been aided by a large group of collaborators, each of whom is to be regarded as of authority in the particular subject which has been entrusted to him. We may specially mention as men whose names are well known and respected on this side of the Atlantic, Dr. Alfred Stenge, of Philadelphia, who edits the section of General Medicine, Dr. David Riesman, who writes on Pathology, and Dr. G. U. Stewart on Physiology. As is necessary in a work of this kind, there is but little room for the expression of individual opinion, since it is necessary to find place for a mention at least of anything new that has appeared during the year. At the same time, a considerable amount of selective care is required from the editors, not merely in judging what views are worthy of notice, but in deciding the relative space to be allowed to each. In addition, each chapter opens with a short summary of the most noteworthy advances made during the year. This feature is of immense convenience to the casual reader, who, not being bent on following any particular lines of study, wishes to grasp in short any new and interesting facts which have arisen. Should he wish to pursue his reading further ample help is given by reference to the original articles. As is perhaps natural, there is somewhat an unnecessary preponderance of reference to American rather than to English and foreign journals, though this is less marked in the sections devoted to pure science, such as those of anatomy and physiology, than in those devoted to clinical and practical work. Coming to the discussion of particular subjects, and choosing a few sections almost at random, we find an excellent though concise description of paratyphoid fever, our principal knowledge of which comes from the States. It is interesting to note that the editors maintain a sceptical attitude with regard to Councilman's discovery of a small-pox parasite, thereby placing themselves rather in line with European opinion than with what appears to be received in their own country. They are also unconvinced as to the necessity of believing in the parasitic origin of carcinoma. Having noted the general lines of investigation in pathology, the editors draw attention in particular fields to three recent developments which they regard as of prime interest. They are the results attained by Poyntan and others in the investigation of the bacteriology of acute rheumatism, the inoculation by Tomaszewski of a monkey with Ducrey's soft chancre bacillus and the inoculation of a monkey with syphilis by Roux. It is, of course, impossible for us to do more than suggest in the vaguest way the scope and style of the book, which in truth covers every subject of medical interest. It is alike invaluable to the busy practitioner, who must acquire his knowledge in concentrated doses, and to the student who will regard it as a critical guide to the original documents. It is furnished with a full and excellent index.

**TEXT-BOOK OF LEGAL MEDICINE. (a)**

TWELVE months ago the first volume of this excellent text-book was reviewed in our columns, and we are pleased to be able to say that this, the second volume, maintains the high standard attained by its predecessor. The book consists of a series of well-written monographs by the best-known American specialists, which have been inserted without change by the editors. For convenience of reference the volume is divided into two parts, of which the section on toxicology forms one. The reader must, in consulting the volume, keep well in mind that throughout the work American law and nomenclature is referred to and quoted, and not British law; and, farther, that the American law is modified in some of the commonwealths. The nomenclature of drugs and chemicals used is that adopted by the United States "Pharmacopœia." The illustrations are numerous, well selected, original, and helpful. Many of them are coloured, and that which shows the spectra of human blood is a model of accuracy and beauty. There are many black and white illustrations and diagrams; but, after all, the value of the book lies in the letterpress. The articles on non-alkaloidal poisons, gaseous poisons, food poisoning, and ptomaines bring before the reader the most recent discoveries in analytical chemistry, bacteriology, and pathological anatomy. The toxicologist will find in them a good and full summary of our most recent knowledge on the subject. Few pages are taken up with the subject of malpractice, which contains many valuable hints for the general practitioner; and we cannot but wish that some of the decisions quoted, especially of English Judges, were more generally known and more frequently acted on, as they would tend to restrain quackery, the tolerance of which is one of the greatest of modern evils.

**Medical News.****Royal College of Physicians, London.**

At a meeting of the College held on July 28th, the following appointments were made:—Censors: Dr. Thomas Henry Green, Dr. William Henry Allchin, Dr. Norman Moore, and Dr. Frederick Taylor. Treasurer: Sir Dyce Duckworth. Emeritus Registrar: Sir Henry Alfred Pitman. Registrar: Dr. Edward Liveing. Harveian Librarian: Dr. Joseph Frank Payne. Assistant Registrar: Dr. Oswald Auchinleck Browne. Elected Members of the Library Committee: Dr. Philip Frank, Dr. Norman Moore, Dr. William Henry Allchin, and Dr. Archibald Edward Garrod. Curators of the Museum: Dr. William Howship Dickinson, Dr. Henry Charlton Bastian, Dr. William Cayley, and Dr. John Abercrombie. Finance Committee: Dr. George Fielding Blandford, Dr. James Frederick Goodhart, and Sir Isambard Owen. Examiners: Chemistry and Chemical Physics: Mr. Harold B. Dixon, F.R.S., Mr. John Millar Thomson, F.R.S., Mr. Frederick Daniel Chattaway, Ph.D., D.Sc., Mr. Alexander Mitchell Kellas, F.C.S., and Mr. John Addyman Gardner, F.C.S., F.I.C. Materia Medica and Pharmacy: Dr. Frederick Willcocks, Dr. Walter Essex Wynter, Dr. Henry Albert Caley, Dr. Francis Whittaker Tunnicliffe, and Dr. James Purves Stewart. Physiology: Dr. Ernest Henry Starling, Dr. Bertram Louis Abrahams, and Dr. Leonard Erskine Hill. Anatomy: Dr. Bertram C. A. Windle, F.R.S., and Dr. Robert Howden. Medical Anatomy and Principles and Practice of Medicine: Dr. Samuel Hatch West, Dr. Theodore Dyke Acland, Dr. George Newton Pitt, Dr. Sidney Philip Phillips, Dr. William Pasteur, Dr. William Collier, Dr. Norman Dalton, Dr. Frederick John Smith, Dr. Francis George Penrose, and Dr. John Rose Bradford, F.R.S. Midwifery and Diseases Peculiar to Women: Dr. Alfred Lewis Galabin, Dr. Francis Henry Champneys, Dr. George Ernest Herman, Dr. William Rivers Pollock.

(a) "A Text Book of Legal Medicine and Toxicology." Edited by Frederick Peterson, M.D., President of the New York State Commission in Lunacy; Clinical Professor of Psychiatry, Columbia University, New York; and Walter S. Haines, M.D., Professor of Chemistry, Pharmacy, and Toxicology to the Rush Medical College, Chicago; Professorial Lecturer on Toxicology in the University of Chicago. In 2 vols. Vol. II. Philadelphia, New York, London: W. B. Saunders and Co. 1904.

and Dr. Edward Malins. Public Health: Part I.—Dr. Arthur Pearson Luff. Part II.—Dr. William Heaton Hamer.

**Royal Veterinary College, Edinburgh.**

As it has now been definitely settled to transfer "the new veterinary College" from Edinburgh to Liverpool, in October, the original "Royal Veterinary College," founded by the late Professor Dick eighty years ago, will henceforth be the only one for veterinary students in the Northern capital, the rivalry of the "new" college will cease, and we hope it will again attain the former success which marked its progress in years gone by, the opinion being generally expressed that the profession is too small to support two institutions of the kind in Scotland. The Royal or Dick's, as it is more familiarly called, covers an extensive site in Edinburgh, and is provided with more complete laboratories, dissecting rooms, class rooms, museum, and anatomical departments than any similar Institution in the United Kingdom, with a professional staff of both veterinary and medical practitioners of considerable eminence.

**Senate of the Royal University of Ireland.**

MR. CHARLES CRAIG, last week, in the Commons, asked the Chief Secretary to the Lord Lieutenant of Ireland whether his attention had been called to a meeting of the Royal University Graduates' Association held in Belfast on July 18th, at which Dr. Leslie was unanimously selected as the candidate whose claims should be brought before the Government for appointment to the vacancy on the Senate of the Royal University caused by the death of Dr. William McKeown; and whether, having regard to the fact that the Royal University Graduates' Association represented the opinions of a large proportion of the graduates of the Royal University and of the public in the North of Ireland and that the late Dr. McKeown was the representative of this opinion in the Senate, the Government would appoint Dr. Leslie to the vacant seat to preserve the continuity of representation of this opinion. Mr. Wyndham said:—"Representations have been made in favour of the appointment of Dr. Leslie to fill the vacancy on the Senate caused by the death of Dr. McKeown. These will be considered by the Government."

**Management of Horton Lunatic Asylum.**

MR. WHITMORE, in the Commons last week, asked the President of the Local Government Board whether his attention had been called to the case of R. S. Clarke and others, tried at last assizes at Guildford, on July 19th, and to the finding of the jury that they were of opinion that the Horton Lunatic Asylum had been grossly mismanaged and that the conduct of the persons responsible for the administration of the Asylum should be at once seriously inquired into; and whether he proposed to take any action in the matter. Mr. Akers-Douglas said:—"My right honourable friend has asked me to answer this question. I am informed by the Commissioners in Lunacy that the matter is receiving careful consideration and that they are awaiting the report of a sub-committee appointed by the Asylums Committee of the London County Council to inquire into the question.

**Death from Anthrax.**

MR. MACDONA asked the Secretary of State for the Home Department whether he was aware that at an inquest recently held in Liverpool upon a man who had died from anthrax it came out in the evidence that the deceased was shaved by a barber in Liverpool shortly before his death, who, at deceased's request, cut open the swelling upon the deceased's face, thus causing a serious risk of anthrax being further spread, and, if so, whether he would take steps to prevent a recurrence of such action. Mr. Akers-Douglas replied:—"I am informed that the facts are as stated in the first part of the question. The matter is entirely outside the scope of the Factory Act and I have no power to take any action, but I may say that I am advised that the risk of anthrax being spread in this way would be small."

**An Irish Question.**

MR. HAYDEN asked the Chief Secretary to the Lord

Lieutenant of Ireland whether he could state the total number of assistant medical officers of lunatic asylums in Ireland and of these how many were married. Mr. Wyndham said:—"The total number of assistant medical officers in district asylums is thirty-five. No married man can be appointed to this position. I have no information as to marriages, if any, contracted subsequently to appointment."

#### University of Durham.

A MEETING of members of the University of Durham was held on July 25th, in the Owens College Union Rooms, for the purpose of forming a "Manchester Association of Members of the University of Durham." Further information may be had from Mr. Bennett, Secretary, 309, Waterloo Road, Manchester.

#### Chicken-Pox.

THE London County Council has decided that chicken-pox shall be a notifiable disease for a further period of three months.

#### Royal College of Physicians, London.

THE following candidates, having passed the requisite examinations, were admitted Members of the College on July 28th:—John Frederick Gordon Dill, M.A., M.D.Cantab.; Edward Henry Douty, M.A., M.D.Cantab., L.R.C.P.Lond.; Wilfred Stephen Fox, M.A.Cantab., L.R.C.P.Lond.; Ernest Edward Glynn, M.A., M.B.Cantab., L.R.C.P.Lond.; Henry Lawrence McKisack, M.D.R.U.I.; Geoffrey Richard Slade, M.A., M.D.Cantab., L.R.C.P.Lond.; and Thomas Grainger Stewart, M.B.Edin.

At the same meeting the L.R.C.P.Lond. was granted to 115 gentlemen who had passed the required examination.

Diplomas in Public Health were also granted to the following:—Charles Thomas Blackwell (Major R.A.M.C.), M.D.Durh., L.R.C.P. & S.Edin.; Dunstan Brewer, L.R.C.P.Lond., M.R.C.S.Eng.; John Catto, M.B., B.S.Aberd.; Basanta Kumar Chatterjee, L.R.C.P. & S.Edin., L.F.P.S.Glasg.; Stanley Cornell Clapham, L.R.C.P.Lond., M.R.C.S.Eng., M.B., B.S.Durh.; John Matthewson Clements, M.B., B.Ch.R.U.I.; Walter Ernest Llewellyn Davies, L.R.C.P.Lond., M.R.C.S.Eng.; Thomas Stokoe Elliot, L.S.A.; Norman Faichnie (Major R.A.M.C.), M.B., B.S.Durh.; Henry William Grattan (Captain R.A.M.C.), L.R.C.P.Lond., M.R.C.S.Eng.; John William Gromitt, L.R.C.P.Lond., M.R.C.S.Eng.; Hugh Llewellyn Jenkins, M.B., Ch.B. Vict.; John Isaac Pratt, L.R.C.P.Lond., M.R.C.S.Eng., M.B.Toronto; Morgan James Rees, L.R.C.P.Lond., M.R.C.S.Eng., M.B.Lond.; Frank Ernest Rock, L.R.C.P.Lond., M.R.C.S.Eng., M.D.Lond.; Godfrey William Simpson, L.R.C.P.Lond., M.R.C.S.Eng.; Charles Augustus Spooner, L.R.C.P. & S.Edin., L.F.P.S. Glasg.; John Charles Baron Statham (Captain R.A.M.C.), L.R.C.P.Lond., M.R.C.S.Eng.; John Robert Steinhäuser, L.R.C.P.Lond., M.R.C.S.Eng., M.B. & B.S.Lond.; Robert Lewis Thornley, L.R.C.P.Lond., M.R.C.S.Eng., M.D.Lond.; Philip Vickers, M.B., Ch.B.Edin.; and William McConnel Wanklyn, L.R.C.P.Lond., M.R.C.S.Eng.

#### Royal College of Surgeons of Edinburgh.

At a meeting of the College held on July 28th, the following gentlemen, having passed the necessary examinations, were admitted Fellows of the College:—David Macrae Aitken, M.B., Ch.B., Robert Gordon Bell, M.D., Chiranjiva Bharadwaja, L.R.C.S.E., William Thomas Chenhall, M.D., Frederick Gardiner, M.D., Alfred Griffiths, M.B., C.M., Arthur Gwyther, M.B., C.M., Captain I.M.S., Thomas Dufour Halaban, M.B., Claude Somerville Hawkes, M.R.C.S.Eng., Edmund Moritz Illington, M.R.C.S.Eng., Captain I.M.S., James Frederick Merrillees, M.B., Ch.B., Thomas Mill, M.B., Ch.B., Philip Henry Myles, M.B., L.R.C.S.E., Lionel Charles Peel Ritchie, M.B., Ch.B., Oscar Bagster Trumper, M.B., Ch.B., and Henry Woolmington Webber, M.D., M.R.C.S.Eng. The medal and set of books forming the "Bathgate Memorial Prize," presented to the College by Colonel William Lorimer Bathgate in memory of his late father, William McPhune Bathgate, Fellow of the College, was awarded to Mr. Robert Macnaught Glover, Carlton House, Dumfries.

#### University of Liverpool.

THE following candidates (arranged alphabetically) have passed the second M.B. and Ch.B. examination:—

A. *Anatomy and Physiology*.—J. W. Cropper, and G. W. Williams.

B. *Materia Medica and Pharmacy*.—T. T. Apsimon, E. R. Armstrong, A. C. Edwards, S. J. C. Holden, A. Jones, T. Martlew, W. R. Pierce, J. H. Rawlinson, A. M. M. Roberts, R. S. Taylor, and S. V. Tinsley.

The following have passed the final M.B. and Ch.B. examination:—

Part I.—J. F. Edmiston, B. T. J. Glover, T. E. Jones, J. F. McCann, J. McClellan, S. W. McLellan, R. H. Mole, L. D. Napier, T. W. Parry, C. H. Smith, F. H. Storey, C. Yorke, and W. Yorke.

Part II.—The following candidates have passed the final examination for the Degrees of Bachelor of Medicine and Bachelor of Surgery with Second Class Honours:—P. Hick, and T. F. Walker.

The following candidates have passed the final examination for the Degrees of Bachelor of Medicine and Bachelor of Surgery:—A. E. Grisewood, W. L. Hawksley, G. J. Keane, W. A. Kidd, and G. C. Scott.

The following candidate has passed the examination for the Diploma in Public Health:—D. T. Barry, M.D.

The following candidates have passed the examination for the Diploma in Tropical Medicine:—T. M. Clayton, M.B., B.S., Saikunzafor Khan, M.B., B.S. Hehir, Major I.M.S., M.D., F.R.C.S., A. R. Maclurkin, M.B., Ch.B., J. E. Nicholson, Lieut.-Colonel R.A.M.C., M.R.C.S., L.R.C.P., N. Phillipson, L.R.C.P., and S. Edin.

#### Army Medical Service.

THE following is an official list of candidates who were successful at the recent examination in London for Commissions in the R.A.M.C. (arranged in the order of merit), for which 40 candidates entered.

William Byam, M.R.C.S.Eng., L.R.C.P.Lond.  
Charles Ryley, M.R.C.S.Eng., L.R.C.P.Lond., D.P.H.  
Harry Theodore Wilson, M.R.C.S.Eng., L.R.C.P.Lond.

Lionel Victor Thurston, M.R.C.S.Eng., L.R.C.P.Lond.

Walter Hyde Hills, M.B., B.C., and B.A.Cantab.  
Patrick Dwyer, M.B., B.Ch.R.U.Irel.  
Phillip Claude Davy, M.R.C.S.Eng., L.R.C.P., M.B.Lond.

John Forbes Cock Mackenzie, M.B., B.S.Melbourne.  
Arthur William Gater, M.R.C.S.Eng., L.R.C.P.Lond.  
George Alfred Duncan Harvey, L.R.C.P. & S.Irel.  
Harold Charles Winckworth, M.R.C.S.Eng., L.R.C.P.Lond.

James Campbell, M.B., B.Ch.R.U.Irel.  
Richard Collis Hallows, M.B., B.Ch., B.A.O., B.A.Dub.

Harry William Russell, M.B., B.Ch.Vict.  
George Richard Painton, M.R.C.S.Eng., L.R.C.P.Lond.

Meurice Sinclair, M.B., B.Ch.Ed.  
Evelyn John H. Luxmore, M.R.C.S.Eng., L.R.C.P.Lond.

Kenneth Alan C. Doig, M.R.C.S.Eng., L.R.C.P.Lond.  
Herbert Owen M. Beadnell, M.R.C.S.Eng., L.R.C.P.Lond.

Herbert St. Maur Carter, M.D., M.B., B.Ch., B.A.Dub.  
Robert Harry L. Cardner, M.R.C.S.Eng., L.R.C.P.Lond.

John Patrick Lynch, L.R.C.P. & S.Irel.  
Alastair Norman Fraser, M.B., B.Ch.Ed.  
Nelson Low, M.R.C.S.Eng., L.R.C.P.Lond.  
Percy Arnold Jones, M.R.C.S.Eng., L.R.C.P., B.A.Cantab.

Cecil Roy Millar, L.R.C.P. & S.Irel.  
Augustine Thomas Frost, M.D., B.Ch.R.U.I.  
George Herbert Richard, M.R.C.S.Eng., L.R.C.P.Lond.

Harry Christopher Sidgwick, M.R.C.S.Eng., M.B. & B.A.Cantab.

John St. Aubyn Maughan, L.R.C.P. & S.Edin., L.F.P. & S.Glasg.

## Notices to Correspondents, Short Letters, &c.

**CORRESPONDENTS** requiring a reply in this column are particularly requested to make use of a *distinctive Signature or Initial*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

**ORIGINAL ARTICLES** or **LETTERS** intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

MR. MILNE is thanked for his communication.

**A PROVINCIAL PRACTITIONER.**—The title of the journal referred to was changed in the hope of a wider field; it did not however succeed, and was finally discontinued some two or three years since.

**EDINBURGH.**—The book is an excellent one, you cannot do better than study its contents before going up for your final.

### THE LANGUAGE OF MEDICINE.

[The doctor certified that he was suffering from epistaxis.—Police Report.]

Of doctor's language I must hold  
That there is this to claim for it,  
That when I have a beastly cold,  
I like some other name for it.  
And oh! how soothing doctors are  
To call it bronchial catarrh.

With new and active sympathies  
Friends look—or so we dream—at us,  
To learn we have a skin disease,  
We fear, is exanthematous.  
But how their pity'd fade to find  
'Twas measles—of the German kind.

We must feel pride on learning how  
Distressing our ingultus is:  
We like the new complaint, but vow  
The one way to insult us is  
To hint it is that vulgar thing  
Far better known as hiccuping.

And Polysyllables of size.  
In 'itis' if they terminate,  
Impress with sorrow and surprise  
seven hearers, I affirm, in eight.  
So delicately each reveals  
The pains that Little Mary feels.  
When to such terms the doctor lends  
His countenance and signet, he  
Wakes envy in the patient's friends  
And gives disease such dignity,  
That mortals yearn and sigh for still  
The happiness of being ill.

M.—*Daily Chronicle*.

DR. J. E. R.—The appeal by Mr. Labouchere in the case of "Dakyl v. Labouchere" for a new trial on the score of misdirection has succeeded, but this will not come on before the Autumn sittings of the Court. The costs in the appeal case will carry those of the first trial whatever the ultimate verdict.

## Vacancies.

- Devon County Asylum.—Assistant Medical Officer. Salary £125 per annum, with board and lodgings. Applications to the Medical Superintendent, Asylum, Exminster.
- Dumfries and Galloway Royal Infirmary. Assistant Medical Officer. Salary £80 per annum, with board and washing. Applications to Mr. Symons, Secretary and Treasurer, 14, Irish Street, Dumfries.
- Hulme Dispensary, Dale Street, Stretford Road, Manchester.—House Surgeon. Salary £150 per annum, with apartments, attendance, coal, and gas. Applications, to the Honorary Secretary Medical Committee.
- Hereford County and City Asylum.—Senior Assistant Medical Officer. Salary £150 per annum, with board, lodging, and laundry. Applications to the Medical Superintendent.
- Mount Vernon Hospital for Consumption and Diseases of the Chest, Hampstead and Northwood.—Resident Medical Officer. Salary £80 per annum, with board and residence. Applications, to William J. Morton, Secretary, 7 Fitzroy Square, W.
- Royal Lancaster Infirmary.—House Surgeon. Salary £100 per annum, with residence, board, attendance, and washing. Applications to the Secretary.
- County Asylum, Rainhill, near Liverpool.—Assistant Medical Officer. Salary £150 per annum, together with furnished apartments, board, attendance, and washing. Applications to the Medical Superintendent.
- South Shields Union.—Assistant (Resident) Medical Officer. Salary £200 per annum. Applications to J. W. Coulson, Clerk to the Guardians, Union Offices, South Shields.

## Appointments.

- BLACKALL, J. J., M.D., at S.Q.U.I., Certifying Surgeon under the Factory Act for the Killdybert District of the county of Clare.
- BURTON, H., L.R.C.P.I., L.R.C.S.Eng., Certifying Surgeon under the Factory Act for the Marple District of the county of Chester.
- DWAN, J. H., L.R.C.P.I., L.R.C.S.I., Certifying Surgeon under the Factory Act for the Rathgormuck District of the county of Waterford.
- EAMES, E. S. B., M.B.C.S., L.R.C.P.Lond., Certifying Surgeon under the Factory Act for the Uffculme District of the county of Devon.

- FORBES, JAMES GRAHAM, M.D., D.P.H.Cantab., M.R.O.P.Lond., Assistant Physician to the Metropolitan Hospital, Kingsland Road.
- GRAHAM, E. B., L.R.C.P., F.R.C.S.Edin., Certifying Surgeon under the Factory Act for the Leven District of the county of Fife.
- HANDLEY, W. SAMPOX, M.S.Lond., F.R.C.S., a Hunterian Professor of Pathology in the Royal College of Surgeons of England.
- LACKIE, J. LAMOND, M.D., F.R.C.P.E., Assistant Physician to the Royal Maternity and Simpson Memorial Hospital, Edinburgh, and Examiner in Obstetrics, University of St. Andrews.
- LEICESTER, M. E. M.D., Brux., L.R.C.P., L.R.C.S.Edin., L.S.A., Medical Officer for the No. 3 District of the Liskeard (Cornwall) Union.
- MACDONALD, D. J., M.B., M.S.Aberd., Certifying Surgeon under the Factory Act for the Stornoway District of the county of Ross and Cromarty.
- MCCENRY, D., L.R.C.S., L.R.C.P.Edin., Certifying Surgeon under the Factory Act for the Ballmacarbery District of the county of Waterford.
- MAGRATH, H. G., L.R.C.P., L.R.C.S.Edin., L.F.P.S.Glasg., certifying Surgeon under the Factory Act for the Cranborne District of the county of Dorset.
- MC SWINEY, M., M.B., M.A.O.R.U.I., Certifying Surgeon under the Factory Act for the Johnstown District of the county of Cork.
- QUIKKE, J., L.R.C.P.I., L.R.C.S.I., Certifying Surgeon under the Factory Act for the Piltown District of the county of Kilkenny.
- SPON, HARRY JAMES, M.B.C.S.Eng., L.R.C.P., D.P.H.Camb., surgeon to the Surrey Dispensary.

## Births.

- DUKA.—On August 3rd, at Lismore, New South Wales, the wife of Albert Theophilus Duka, M.A.Cantab., M.B.C.S., L.R.C.P., D.S.O., of a son. (By Telegram.)
- MELDON.—On August 4th, at 123 Morehampton Road, the wife of Dr. Pugin Meldon, of a daughter.
- ROGERS.—On August 1st, at Charlton, Wimborne Road, Bourne-mouth, the wife of Surgeon Major F. A. Rogers, Indian Medical Service, of a daughter.

## Marriages.

- BOYCOTT—AGG.—On August 4th, at St. Matthew's Church, Westminster, Authur Edwin Boycott, M.D.Oxon, second surviving son of William Boycott, Hereford, to Constance Louisa, second daughter of the late Colonel W. Agg, and of Mrs. Agg of Cheltenham.
- COOPER—BUTLER.—On July 27th, at Turnham Green, William Bertram Cooper, M.R.C.S.Eng., L.R.C.P.Lond., of Chiswick, youngest son of the late W. G. Cooper, of Keaxington, to Esther Maud (Stella), eldest daughter of the late J. M. Butler and of Mrs. Butler of Chiswick.

## OPERATIONS.—METROPOLITAN HOSPITALS.

- WEDNESDAY.—St. Bartholomew's (1.30 p.m.), University College (2 p.m.), Royal Free (2 p.m.), Middlesex (1.30 p.m.), Charing Cross (3 p.m.), St. Thomas's (2 p.m.), London (2 p.m.), King's College (2 p.m.), St. George's (Ophthalmic, 1 p.m.), St. Mary's (2 p.m.), National Orthopaedic (10 a.m.), St. Peter's (2 p.m.), Samaritan (9.30 a.m. and 2.30 p.m.), Gt. Ormond Street (9.30 a.m.), Gt. Northern Central (2.30 p.m.), Westminster (2 p.m.), Metropolitan (2.30 p.m.), London Throat (9.30 a.m.), Cancer (2 p.m.), Throat, Golden Square (9.30 a.m.), Guy's (1.30 p.m.).
- THURSDAY.—St. Bartholomew's (1.30 p.m.), St. Thomas's (3.30 p.m.), University College (2 p.m.), Charing Cross (3 p.m.), St. George's (1 p.m.), London (2 p.m.), King's College (2 p.m.), Middlesex (1.30 p.m.), St. Mary's (2.30 p.m.), Soho Square (2 p.m.), North-West London (2 p.m.), Chelsea (2 p.m.), Great Northern Central (Gynaecological, 2.30 p.m.), Metropolitan (2.30 p.m.), London Throat (9.30 a.m.), St. Mark's (2 p.m.), Samaritan (9.30 a.m. and 2.30 p.m.), Throat, Golden Square (9.30 a.m.), Guy's (1.30 p.m.).
- FRIDAY.—London (2 p.m.), St. Bartholomew's (1.30 p.m.), St. Thomas's (3.30 p.m.), Guy's (1.30 p.m.), Middlesex (1.30 p.m.), Charing Cross (3 p.m.), St. George's (1 p.m.), King's College (2 p.m.), St. Mary's (2 p.m.), Ophthalmic (10 a.m.), Cancer (2 p.m.), Chelsea (2 p.m.), Great Northern Central (2.30 p.m.), West London (2.30 p.m.), London Throat (9.30 a.m.), Samaritan (9.30 a.m. and 2.30 p.m.), Throat, Golden Square (9.30 a.m.), City Orthopaedic (2.30 p.m.), Soho Square (2 p.m.).
- SATURDAY.—Royal Free (9 a.m.), London (2 p.m.), Middlesex (1.30 p.m.), St. Thomas's (2 p.m.), University College (9.15 a.m.), Charing Cross (2 p.m.), St. George's (1 p.m.), St. Mary's (10 p.m.) Throat, Golden Square (9.30 a.m.), Guy's (1.30 p.m.).
- MONDAY.—London (2 p.m.), St. Bartholomew's (1.30 p.m.), St. Thomas's (3.30 p.m.), St. George's (2 p.m.), St. Mary's (2.30 p.m.), Middlesex (1.30 p.m.), Westminster (2 p.m.), Chelsea (2 p.m.), Samaritan (Gynaecological, by Physicians, 2 p.m.), Soho Square (2 p.m.), Royal Orthopaedic (2 p.m.), City Orthopaedic (4 p.m.), Great Northern Central (2.30 p.m.), West London (2.30 p.m.), London Throat (9.30 a.m.), Royal Free (2 p.m.), Guy's (1.30 p.m.).
- TUESDAY.—London (2 p.m.), St. Bartholomew's (1.30 p.m.), St. Thomas's (3.30 p.m.), Guy's (1.30 p.m.), Middlesex (1.30 p.m.), Westminster (2 p.m.), West London (2.30 p.m.), University College (2 p.m.), St. George's (1 p.m.), St. Mary's (1 p.m.), St. Mark's (2.30 p.m.), Cancer (2 p.m.), Metropolitan (2.30 p.m.), London Throat (9.30 a.m.), Royal Ear (3 p.m.), Samaritan (9.30 a.m. and 2.30 p.m.), Throat, Golden Square (9.30 a.m.), Soho Square (2 p.m.).

## Original Communications.

### THE STUDY OF BIONOMICS IN RELATION TO THE DIMINISHING BIRTH-RATE.

By W. R. MACDERMOTT, M.B.

I HAD written a criticism of Dr. J. W. Taylor's article on the declining birth-rate intended for this journal and laid it by, only to find it anticipated in material respects by Dr. David Walsh. Not, however, completely or to the exclusion of what I thought the most essential point. That point I find well stated in a leading article in THE MEDICAL PRESS AND CIRCULAR of July 27th, 1904, to the effect "that the whole matter appears to be on the borderland where laws are beginning to loom from the dense mists of half knowledge and speculation." This statement recalled to my mind the article I had written, as it put tersely the position I had taken in it. But the question further occurred to me why this should be the case, whether from the inherent difficulty of the subject itself or from a vicious method of studying it, a method vitiated by non-scientific deference to traditional preconceptions.

In Ireland the birth-rate has fallen more than, I venture to say, in any country in Europe. Again, it has fallen most in rural districts, least in the cities. Thus, in the report of the Registrar-General for the quarter ending March 31st, 1904, the birth-rate for Dublin is 32.4, while the average rate for the Leinster counties is about 22. The rate for Belfast is 31.5; for Ulster, including Belfast, 24.4.

I am sure every Irish medical man will agree with me in saying that the practices to which Dr. Taylor ascribes the fall in the birth-rate are unknown in Irish rural districts, exactly where the rate is lowest, and that in the cities, where it is highest, they cannot prevail to such an extent as to materially affect it.

I believe it would be found on examination that the same thing holds true for wide areas in Great Britain, and even in France and America, namely, that in these areas there is not so much a falling, as a permanent low natality due to causes among which the practices in question are conspicuously absent.

The birth-rate stated as a fraction per 1,000 of population is a striking example of the fallacy to which statistics so easily lend themselves. The number of both married and marriageable in a thousand persons is variable both as regards time

and place. If the number of persons under 20 and over 45 increase at any time or in any place relatively greater than those between these limits, the fact, as far as it goes, will mean a falling birth-rate. For example, I saw it stated in a late number of *Nature* that 50 per cent. of those born die before they reach 20. If, now, there being 14,647,783 of that age or under in the English population, 32,527,843 (1901), if there is ever so small an increase in the mass of life at 20 and under it will find marked representation in apparently lowering the birth-rate, and a relative increase in the number over 45 in proportion will have the same effect.

Primarily the rate is a potential function of the number of females between 20 and 40, that is, it depends on a numerical variable whatever other factors may intervene. Women under and over these ages bear children, and this, from a certain point of view, *i.e.*, as obtaining ultimate representation in vital status, is a most important fact. The number of children so borne being, however, negligible, the apparent form of the birth-rate can be, immediately, little affected by it.

Fall in the real birth-rate would follow only from women of the age period 20-40 bearing fewer children; it would be illicit reasoning to ascribe any such change to flux in the number of such women in a population undergoing variation. I am here only indicating necessary points for study; space would not allow me to discuss the variation in the number which has occurred in the United Kingdom. It is enough to say that Dr. Taylor's position, to be either strengthened or weakened, needs the variation in the relative number of child-bearing women to be taken into account.

The statistical form of the apparent birth-rate is the expression of variables lying, say, between the limits 30 and 20. Thus, while the birth-rate for Dublin is 32, that for many of the Irish counties is 20 or under. In general the rural is, and always has been, below the urban rate, and, therefore, if the urban population increases or the rural decreases, or both circumstances happen to concur, the apparent birth-rate may rise while the real, the relative number of children borne by women of age period 20-40, may be stationary or falling. The rise in the apparent rate for the United Kingdom beginning in 1840 actually concurred with a great increase in the urban population, that in which the real rate is highest, going with a decrease in the rural population, in which it is lowest. When, however, the rural population becomes relatively insignificant, as it has in the British Islands, or when the flux of population in favour of the high rate attains a maximum, the apparent birth-rate tends to

become stationary or even to fall. It is evident that a great increase in an element of population in which *ab initio* there is a high birth-rate cannot be taken as indicating a flux in the real birth-rate itself.

Apparent local birth-rates are worthless, as a rule, for purposes of inference unless they cover large numbers. Where they cover populations of, say, 100,000, discrepancies are to be noted from place to place which cannot be accounted for by the causes medical men, and Dr. Taylor in particular, assign from a limited point of view as determining relative natality. Recent change in the British birth-rate is probably due to a greater extent to the South African War than to the growth of the practices Dr. Taylor dwells on. In general, the rate, apparent and real, has been, in the main, determined by an impersonal non-volitional cause—*i.e.*, the growth of a great urban industrial class, a growth which varies with the well-being of the class. This vast increase of industrial life is an economic phenomenon almost mechanical in its nature, but it gives the importance of absolute mass to the personal equation; a greater mass of personal frailty and vice comes into the field to strike our minds. But the personal equation covers what works for good as well as what works for evil, and it may be doubtful in the first place that there is any relative increase in the mass of vice, and in the next place whether it is not compensated for by an increase in the mass of virtue or right conduct.

My object here is to insist that medical men should recognise the unity of vital status or bionomics, and not make desultory raids on it as political economists, clergymen and lawyers do from varying points of view. The economy of human life is the end or purpose of the economy of wealth, of morality and jurisprudence. The science of the production and distribution of wealth, morality, and jurisprudence are mere abstractions in themselves saturated in the actual field with the gross fallacies which attend deduction from the abstract. The concrete reality is human life, beginning with the life of the individual. To use a much abused term, theory, in the sense in which Coleridge uses it, we should aim at a theory, a mere true description of the actual nature of the life of the individual and how he actually maintains it by the formation and regulation of social aggregates, the regulation of his own conduct, the production and preservation of wealth, his means of subsistence, and so on.

Now the first fact that presents itself when such description is barely entered on is that the action of the individual is grossly at fault with reference to his primary object, the maintenance of his life; he is inconsequent, ignorant and irrational. For ages his mental ability to oppose the powers of Nature, to master, to use them, lay dormant. For ages he has allowed the devices originally arising to safeguard life and enhance its value to be turned against it. This fact is represented in the description or theory of human life. The moment man began to describe himself he fell into gross error and placed a bar in the way of describing himself in true terms, though these would be the simplest. He lied to himself, whether consciously or unconsciously does not matter, and became a slave to complex and contradictory systems of falsehood. He realised the powers of Nature as divine and remained their slave as long as he did. He described himself as a god, the descendant of a

god; he made his dead fathers and living kings gods, and in so doing built up interests which committed him deeper and deeper to falsehood.

But every fact could not be closed to true description, and truth in one direction led to a general perception of truth, by originating a method of pursuing it. Bionomics, limiting a term used in a wider sense to human life, not only remains barred in every direction by ancient error and the ideals and interests created by such error, but by the non-application of scientific method to its subject matter. "Compared," Alfred Wallace says, "with our astounding progress in physical science and its application, our system of government, of administrative justice and of national education, our entire social and moral organisation remains in a state of barbarism." It would be still more to the point to say that the mere description of our moral and social organisation remains in the "dense mists of half knowledge and speculation," and greatly in the hands of those whose interest it is that it shall remain so.

In a particular study of insanity in Ireland, referred to in an article in the *Westminster Review* (March, 1903), I took in a continuous area all the permanent families and investigated their life history as far as I could go. I found at once that the method carried me far beyond my particular study, among other matters to the birth-rate and marriage in connection with it. In 400 families only in one instance had I reason to suspect the practices Dr. Taylor refers to. In 217 births I found only 5 to be illegitimate; in one of these last the mother was a weak-minded girl; the other four did not belong to my permanent families; were, indeed, servant girls. The apparent birth-rate for the area (1901) was 17 per 1,000; it had fallen within thirty years from 28, and is falling every year, or rather fluctuating wildly, as must be the case where small numbers are under observation. It would take periods of ten years at least to show the fall beyond doubt. The only practices used to prevent child-bearing are protraction of the period of lactation and absolute continence in married life. The last, I believe, is more common than is generally supposed, particularly among the elderly. Ill-health, abnormal states of the uterus and ovaries short of pronounced disease, sexual indifference and personal indifference amounting often to positive dislike, are by no means negligible factors and increase with age of marriage.

Other points of even greater weight occurred to me in this study. My object here is, however, not to give my conclusions but to show that wide and careful observation of the *personnel* of family life is the essential base of human bionomics and that that observation is peculiarly within the province of the practising physician. It seems to me that both Dr. Taylor and his critics have a far finer field for such observation than I have, but forsake it for crude statistics and the inconsequent morality cherished in another profession. What is the use of trotting out potential fecundity, the Malthusian bugbear, when it is a ghost even to herrings? I would leave Count Tolstoi to condemn marriage as an immoral and improper institution, the clergy and lawyers to taboo illegitimacy and excuse celibacy only when they practise it. What are we the wiser when we find Mill and his disciples declaiming against early and improvident, and physiologists against deferred and provident, marriages? We are left in a state of senseless

muddle, left worse even than the mindless creatures of convention and custom who, at least, have something to go by. But the field of actual circumstance is open before us, we know the method of scientific investigation, and surely we ought to know that until we enter it with that method we must remain in the dense mists of half knowledge and speculation.

## ACETOZONE :

### A NOTE ON ITS VALUE AS AN ANTISEPTIC AND GERMICIDE.

By JAMES BURNET, M.A., M.B., M.R.C.P. Edin.,

Clinical Tutor, Extramural Wards, Royal Infirmary; Registrar, Royal Hospital for Sick Children; and Physician to the Marshall Street Dispensary, Edinburgh.

This chemical compound was brought to the notice of the profession in this country about two years ago, although it had already been successfully used for some time in America. The chemical title for this substance is benzoyl-acetyl-peroxide, and its formula may be expressed as  $C_6H_5CoOOC_2H_5$ . Benzozone was the term at first applied to it, but as this closely resembled the names of other antiseptics already in use, it was soon altered to acetozone. Novy and Freer, of the University of Michigan, carried out a series of observations upon the action of a number of organic peroxides on bacteria. They called attention to the fact that acetozone, which is one of these peroxides, when brought into contact with water, splits up, giving rise to the peroxides of acetyl hydrogen and benzoyl hydrogen. These peroxides, when in solution, are very energetic, and act powerfully as germicides. It was claimed for acetozone that it was probably the most powerful bactericidal agent in existence.

A few preliminary remarks on the nature and properties of this substance may not be amiss. Acetozone occurs in the form of fine acicular crystals, and melts at the ordinary body temperature. If heated suddenly decomposition takes place almost instantaneously, and an explosion may result. It is soluble to a small extent in oils, slightly so in alcohol, and fairly soluble in ether and in chloroform. In water its solubility varies from 1 : 1,000 to 1 : 10,000, according to temperature and other circumstances. Alkalies and all forms of organic matter readily decompose it. It is marketed as a powder consisting of equal parts of itself and another inert, absorbent substance. In this form it may be handled with the greatest freedom. As regards its germicidal power, it is stated to be very much more active than corrosive sublimate, while at the same time it is non-toxic, and may be freely administered internally in aqueous solutions.

My methods of employing acetozone were two in number. Most frequently it was used as a watery solution containing  $2\frac{1}{2}$  grains to every four ounces. After thoroughly agitating there resulted a hazy solution, and this was employed almost immediately after its preparation and never later than 48 hours. Occasionally, I found the addition of one part of acetozone to 250 parts of talc—*i.e.*, about one grain to the half ounce—very useful as a dusting powder. I have made use of acetozone in something like sixty cases, and always with the most satisfactory results. Already I have communicated a note on acetozone to another journal, (a) but further experi-

ence of its value warrants me, I think, in publishing the results of my more extended observations in order that others may benefit thereby. The cases in which acetozone was employed, and of which I kept a record, number fifty-three in all. They were of a most varied description, ranging from whitlows and septic wounds to actual gangrene. It is, of course, absolutely impossible to publish notes of all these cases. There are, however, two very interesting clinical histories which I may briefly place on record.

One of the earliest uses to which I put acetozone was in the case of a child of five years. The little finger of his left hand had been severely crushed and lacerated by being trampled on by another boy while at play. He was brought to me immediately after the accident. The finger was split right up the middle of its palmar aspect, and the flaps thus formed were covered with mud and dirt. The terminal phalanx was broken. The parts were first carefully washed with acetozone solution (5 grs. : 8 ozs.). The finger was then dressed with lint wrung out of the lotion and covered over with gutta-percha tissue. The whole hand was then placed on a splint and absorbent cotton wool and a bandage applied. Next morning, when the dressings were removed, the soft parts were quite black and cold. They smelt badly, and seemed as if about to become gangrenous. Nevertheless, the finger was kept in a small basin containing a solution of acetozone for fully fifteen minutes. I then further bathed the parts very carefully and reapplied the dressings. This process was repeated again the same evening. On the third day the parts presented a healthier appearance, and had to some extent lost their former evil odour. The wound was dressed three times. On the fourth morning the gangrenous appearance was almost entirely gone, and the tissues when pressed bled quite freely. Wet dressings were continued until the sixth day, when they were withdrawn altogether, and a dusting powder consisting of acetozone and zinc oxide (2 grs. :  $\frac{1}{2}$  oz.) was freely applied. This, however, caused considerable burning and smarting pain, and consequently the amount of acetozone was reduced by one-half. On the eighth day, as the granulations which were now beginning to spring up were still raw and fresh, they were gently scraped and the flaps brought together by means of a couple of horsehair sutures. The parts were then dusted over with the powder as before. There had been too great delay in bringing the flaps into apposition, and consequently the tissues towards the finger tips refused to be connected, so that this portion remained as a raw, granulating surface. I was, however, afraid to use sutures earlier lest their tension might lead to suppuration in a wound which was by no means healthy-looking to commence with. At the end of a fortnight the finger was practically healed, except the small piece at the tip. The fracture of the terminal phalanx had united, and the child had no longer an ugly, unshapely finger such as had been anticipated. The mother, however, was told to continue dressing it for a short time. Unfortunately, in spite of my instructions to move the joints regularly, she neglected to do so; and consequently, though the child's finger is perfect so far as shape goes, it will presumably always remain stiff and flexed. This is a case where amputation at first seemed almost inevitable, and, indeed, there was no small risk incurred

(a) *The Medical Times*, October 18th, 1902.

in thus temporising with a finger in such a septic and gangrenous-like condition.

The second case to which I wish to refer, and which is of more than passing interest, is that of a woman, *æt.* 49. She had some pain in the left forefinger. She imagined the condition to be a commencing whitlow, and applied a piece of lint soaked in pure carbolic acid, covering it over with gutta-percha tissue. This dressing was kept on from Friday morning till late on Saturday afternoon. As she felt the finger cold and numb she removed the dressing, and to her surprise found the finger purplish-black in colour from its tip right up to the middle of the second phalanx. I was accordingly sent for, and found the parts quite anæsthetic. On pushing a needle deeply into the finger at different places no blood oozed out. In other words, the patient was suffering from the condition known as carbolic gangrene. Moist dressings of acetozone were applied and the finger well covered up with a thick wrapping of cotton-wool. The patient passed a restless night. She had great pain over the second phalanx of the affected finger. In the morning, on removing the dressings, it was noted that a fairly well marked line of demarcation was already beginning to form. I placed the finger in a solution of acetozone, and kept it there for fully half an hour. The moist dressings were then reapplied. This process was repeated in the afternoon, and again in the evening. Next morning, the patient experienced sensation slightly over the second and to some extent also over the third phalanx. When these parts were pricked with a needle bright red blood oozed out. The treatment with acetozone was kept up for a week, and at the end of that time only the very tip of the finger remained anæsthetic. The skin

over the other parts was beginning to assume a more natural appearance. The parts about the terminal phalanx, however, still looked far from healthy, and although it was now evident that amputation of the finger was no longer called for, it was thought that in all probability the terminal phalanx, or at least part of it, would eventually perish. In the course of a few weeks all the unhealthy skin and most of the underlying soft parts

were removed, and the remaining tissues kept constantly under the influence of acetozone. Finally, the bulk of the nail was taken off, leaving only the matrix behind. The photograph shows very well the condition of the finger two months after the commencement of treatment. After the finger was photographed the projecting part of the terminal phalanx was removed, and at the present time the patient has as perfect a finger as she could well wish for. Its movements are not at all impaired, and the fact that it is slightly shorter than the corresponding one of the other hand is scarcely noticeable. This case proves the possibility of treating carbolic gangrene without amputation.

I have mentioned these two cases in some detail because they were serious ones, at all events they involved the probable loss of a finger. Acetozone, however, has been chiefly employed in the treatment of ordinary affections such as whitlows, abscesses, and small septic wounds in general. After freely incising a whitlow or other abscess the application of moist acetozone dressings brings about a rapid cure, and this mode of treatment is, moreover, devoid of the risks involved where carbolic acid or lysol is used. So, too, with boils and carbuncles. Abscesses, even when extensive, cause little trouble if, after incising them and squeezing out the purulent contents, the cavity is flushed out with acetozone solution, and then stuffed with gauze saturated with the same. Wounds which are already septic speedily become healthy when dressed with lint wrung out of a watery solution of acetozone and covered over with gutta-percha tissue.

In a case of cystitis due to urethral stricture, acetozone was found of great value. The patient was 50 years of age, and had a very tight stricture. To relieve this he had been passing, or at least attempting to pass, a very septic-looking gum-elastic catheter. After relieving the stricture the cystitis remained. Many internal remedies were used for its relief, but these only gave slight results. Accordingly the bladder was thoroughly washed out with a weak solution of acetozone. This was followed by marked improvement. A week later the washing-out process was repeated, and from that time the cystitis rapidly disappeared. So far as I am aware, acetozone has never been used in this way before, and consequently it might be worth trying in similar cases. In this patient's case it certainly had a very definite and speedy effect. This leads me to suppose that acetozone would be valuable in puerperal septicæmia. It might not only be used as an intra-uterine douche in such cases, but might also be given internally in the hope that it might thus counteract the evil effects of the toxins circulating in the blood. Already it has been used with some success in appendicitis, as well as in dysentery and in enteric fever; and elsewhere I suggested its use as an intestinal antiseptic in cholera and in tuberculous affections.

There are one or two points which must be carefully noted in using acetozone. If used in too great strengths it causes considerable smarting and pain. On the other hand, it may, within certain limits, be administered internally in comparatively large amounts. In fact, to obtain good results from its internal administration acetozone must be given freely and in heroic doses. This is especially so in cases of enteric fever. Solutions

should always be freshly prepared, and only water should be used as a solvent. I do not think the action is quite so powerful when hot water is employed in making the solution as when cold is made use of. I noticed, at all events on several occasions, that when a standard solution had been prepared and before use was diluted to the necessary strength with hot water the results obtained, so far as therapeutic effect was concerned, were not quite so good as when the dilution was made with cold water. The reason may be that hot water causes too rapid a disintegration of this compound. So far as my experience goes acetozone may be stated to have no deleterious effect on metal instruments. Its very pleasant odour is another recommendation of no little consequence in many instances. Time alone forbids a further consideration of the many possibilities of this new preparation, but these imperfect notes may serve as an introduction to those as yet unacquainted with the virtues of this antiseptic and germicide.

### A CASE OF SUPPURATIVE KNEE-JOINT.

By A. R. BRACKETT, M.A., M.D.

R. J., æt. 10, family history good, robust, healthy boy. While playing marbles on the floor, thrust into his knee-joint a needle which lay unobserved upon the floor. The needle was threaded with about six or eight inches of ordinary black cotton thread. It penetrated the joint eye first, carrying the thread with it. The joint was penetrated on its internal aspect, about one and three-fourths inches posterior to the patella, the needle breaking in two pieces, the larger of which was withdrawn at once. The smaller portion with the eye remained in the joint, the ends of the thread which it carried hanging out several inches. At the request of the child, "because it pulled," the mother cut the threads flush with the skin, allowing the remaining part of the thread attached to the needle (which proved to be over two inches long) to disappear under the skin, thus transforming the proposition to a "hunt for a needle in a haystack." Infection promptly occurred. At the end of a week, when called to see the case in consultation, the child was suffering from an intensely septic synovitis, decided general toxæmia, and great pain. The temperature stood at 104½° F. Pulse, 130; respirations were correspondingly rapid, but were not counted; had had several chills, followed by sweating.

Operation was advised at once, but the practitioner in charge objected. The parents, however, becoming alarmed, brought him to the hospital the following day. Before operating an X-ray picture was secured, both in the antero-posterior axis of the limb and in the lateral axis. The shadow of the needle fragment was readily seen. Taking the planes shown by these two pictures as a guide, the joint was freely opened, first on the internal aspect. By good fortune our first incision came within the width of a knife blade of the foreign body, exposing also a portion of the thread. Following this up made the fragment of needle easy to find. It was imbedded nearly a quarter of an inch in the internal condyle of the femur. After its removal the joint, which was full of pus, was opened on the external surface by an incision parallel to, and equal in length (about three and a half inches), to the opposite one; with a dull periosteotome the patella was elevated sufficiently to allow of complete through-and-through irrigation of the joint. This was done with dioxygen, pure, and repeated until the reaction was very slight. Drainage-tubes were inserted, plain gauze dressing applied, thickly covered with absorbent cotton, fixation secured by a fenestrated splint, and the patient put to bed.

His temperature rapidly came down, his pulse also; pain ceased except when limb was moved. The following morning the temperature by rectum was 99° F.,

pulse 90. The knee was uncovered, and a second thorough irrigation of the joint was made. At the end of seventy-two hours, temperature and pulse were entirely normal, and the little fellow was begging for food, and to be allowed to get up. The drainage-tubes were now removed, the sutures that had been inserted but not tied were drawn together, closing the wound, not, however, without some misgiving as to the possibility that re-opening and re-draining might be necessary. Our fears were groundless, for primary union promptly followed. In ten days the little patient was out of bed and the splints removed; on the sixteenth day, in spite of orders to the contrary, the patient walked some distance from the hospital with a very slight limp; on the eighteenth day he went home. Now, two years after the injury, he has a flexible and perfect knee-joint. The infection in this case was prompt in developing and virulent in its character, manifested both locally and constitutionally, consequently our prognosis could not be other than unfavourable. Under such conditions a "stiff knee-joint" would ordinarily be considered a good result. That we did not have such a result is due to two factors: First, the thorough drainage established; and second, to the equally thorough and beneficent action of the antiseptic solution that was used. I am by no means tied to any one technique nor to any one of the many antiseptic preparations that have become, so to speak, classic. But after a fairly extensive experience covering a number of years, I am unable to name any reagent that can so satisfactorily accomplish what is demanded of it as dioxygen. Other reagents are germicidal, but they are also toxic. They accomplish antiseptis, it is true, but they are more or less irritating and frequently, as in the case of "corrosive sublimate" so commonly used, have a destructive action on the cellular structures in living tissue, even to the extent of a superficial necrosis. Many of them are disagreeable in odour, consequently distasteful to patients—no unimportant factor in the presence of sensitive stomachs and pain-racked nerves. None of them develop by their action a "mechanical force" (if we may use the term) that materially assists in dislodging and clearing out ingrained particles of infectious substances, as seen in the bubbling of applied dioxygen, which is non-toxic, non-irritating, and germicidal. In giving off its oxygen it seems really to vivify the structures with which it is brought in contact and hasten constructive metabolism.

### THYROID GRAFTING IN HUMAN BEINGS.

By H. CHRISTIANI, M.D.;

Professor at the Faculty of Medicine of Geneva.

THE attempts at thyroid grafting hitherto performed in man may be divided into two distinct groups, *e.g.*, heterothyroid grafts, that is to say, the transplantation of thyroid grafts from animals to man, and homo-thyroid grafts, *viz.*, transplantation of human thyroid gland.

Most of the experiments in the direction of transplanting thyroid grafts from animals to man have been done with sheep's thyroid, following the example set by Sir Victor Horsley. An entire lobe or large portions of the gland are removed from the animal and are buried in the connective tissue of this or that region. All these experiments gave immediate good results, but in all, after a variable space of time, the thyroid tissue showed signs of atrophy, the longest period being two months.

Grafts of human thyroid were made in 1883 by M. Kocher and others, the material having been obtained for the most part from human thyroid glands that had been extirpated. The results of this method of implantation were not, on the whole, more favourable than those obtained by grafts of animal thyroids.

These results offered so little encouragement that certain observers recently engaged in the problem of

thyroid medication have been tempted to relegate thyroid implantation to the limbo of impracticable therapeutical projects.

Nevertheless, if we review all these experimental investigations and compare the results of direct experiment, we find ourselves in a position to draw conclusions somewhat less negative in character. It must be admitted that Shiff's experiments in thyroid implantation, which were the starting-point of this line of research, yielded no persistent results, and various physiologists, pursuing the same line, were not more fortunate. When, fifteen years ago, I first took up the study of the thyroid gland, the general opinion was that the transplanted gland would either undergo necrosis and speedy absorption or grow for a time, only to disappear later on—invariably in a comparatively short space of time—by slow atrophy.

But in these investigations the anatomical factor seems to have been lost sight of, attention having been directed exclusively to the physiological side of the question. Von Eiselsberg was the first to show, not only that thyroid grafts in ecthyroidised animals might save life, but also that the transplanted thyroid was capable of maintaining its distinctive structure. My earliest observations, published at about the same time, confirmed Eiselsberg's researches, and more recent investigations demonstrate conclusively that it is possible to obtain permanent grafts and, incidentally, to explain why previous grafts had failed to gain a stable footing. It thus became possible to formulate certain rules to be observed in practising these grafts, rules which we are fain to observe under penalty of failure. It is unnecessary here to give details, but these rules may be summarised as follows: (1) The graft must be homothyroid; (2) only normal living tissue must be transplanted; and (3) small multiple grafts should be made, taking care to implant them in very vascular regions. By following these rules I have been uniformly successful in obtaining positive and durable results both from the anatomical and the physiological points of view. When, on the contrary, I transplanted the thyroid tissue of an animal belonging to a different species, I invariably noted more or less prompt cytolysis, with disappearance of the graft. Similarly, if the graft were dead or had undergone changes, it was rapidly phagocytosised, destroyed, and absorbed.

If the thyroid fragment be too large, we usually find a more or less extensive zone of necrosis at the centre which cannot possibly undergo regeneration; moreover, the sclerotic process which sets in may jeopardise the vitality of the portion of the graft which has so far maintained its vitality. It is also very important at the time of making the graft to form a clear idea of the approximate requirements of the organism in the matter of thyroid function. If this requirement be non-existent, as in the case of an animal possessed of a normal gland, the graft may take, but its vitality will be low in accordance with the principle that all useless organs undergo atrophy.

In animals partially ethyroidised, the grafts readily take root and manifest remarkable vitality with a tendency to hypertrophy, whereas in animals whose thyroid requirements are too pronounced (as from total thyroidectomy at one sitting), especially if only small grafts are made, these grafts run the risk of being subjected to an excessive strain from the onset. Inasmuch as, at the commencement, that is to say, soon after transplantation, the regeneration of these "neothyroids" is necessarily incomplete, their embryonic vascularity falls short of requirements, consequently these neo-organs may succumb to the burden thrown upon them, and, instead of the characteristic thyroid hypertrophy we may get signs of degenerative lesions with consequent sclerosis and atrophy.

When we pass from the experimental to the clinical domain, other difficulties present themselves. In animals we usually transplant grafts of normal thyroid tissue to normal animals or animals who have been deprived of a part or of the whole of their thyroid gland. This was not always the case in the experiments of grafting in human beings. The persons in whom the grafts were made were, on the contrary,

usually suffering from the effects of partial or total destruction of the thyroid gland.

Now it must be borne in mind that if we practise transplantation on organisms completely deprived of thyroid gland it may happen, especially if the grafts be small in size and few in number, that they fall victims to the fate that overtakes experimental grafts made under similar conditions (overstrain and degeneration). Moreover, it may be that disturbances of general nutrition render the tissues of the organism unsuitable to act as graft beds; the tissues of myxœdematous patients, for instance, are often ill-adapted to the purpose of graft reception.

In addition to the numerous difficulties that present themselves in the attempt to graft the thyroid in man there is another, not the least important, *viz.*, the difficulty of obtaining normal human thyroid substance. It is obviously of the greatest importance to utilise histologically normal gland for our grafts, since those who have so far employed human grafts have invariably made use of altered thyroid tissue—grafts of goitrous gland, for instance—and the pathological characters of the thyroid grafts may not have been altogether foreign to the failures.

In order to protect ourselves against these numerous sources of error, and in order to avoid, in the study of therapeutical thyroid grafts, the groping inseparable from the empirical methods hitherto followed in investigations of this kind, I have systematically proceeded on scientific lines just as in my experimental researches. The first point to establish was whether normal thyroid tissue could be successfully grafted in man. Considerable time elapsed before I could verify this possibility; indeed, it was not until an opportunity occurred in M. Kummer's service in the course of a deep operation on the neck of a girl that I was enabled to place under the skin two small fragments of normal thyroid gland. These two small implantations proved a valuable starting-point for my subsequent attempts at implantation in man.

We next investigated the fate of different human thyroid tissues, normal and diseased, when grafted on diseased organisms, hyper- or dysthyroidian. At the onset we met with certain difficulties, not that the patients objected to such grafts, for they are usually perfectly willing to consent to any measure which holds out promise of ameliorating their unhappy plight, and even to provide the thyroid grafts themselves; but the real difficulty was to study the ultimate fate of these grafts. Nevertheless, we managed to investigate the course of a series of grafts of different kinds, and to examine some of them after extirpation. Each of the patients having received a number of grafts, there could be no objection to our subsequently removing one or two.

Here, briefly narrated, are the three observations on which our conclusions are based:—A girl, *æt.* 20, who underwent an operation on the neck for a non-thyroidal affection and whose gland was found to be normal, provided the grafts, made on September 19th, 1902, one on herself in the supra-clavicular fossa and two on the following patient.

A myxœdematous boy, *æt.* about 12, presented in the region of the left thyroid body a small friable goitre, of a whitish tint on section. This had been extirpated. The left lobe was small, pale, and its consistence resembled that of the goitrous lobe. He was grafted (1) with the normal thyroid body of the girl just referred to; (2) with thyroid substance from the next patient; and (3) with fragments of the left lobe of his own thyroid.

The next patient was a woman, *æt.* 34, in good health in spite of the fact that she had a goitre on the left side, which was extirpated, while the right lobe appeared to have undergone little change. Two series of grafts were made in this case—(1) with the right lobe of her own thyroid, and (2) with the left thyroid lobe of the previous patient.

For the purpose of these grafts, then, we made use of three classes of thyroid: first, normal thyroid substance (first patient); slightly altered substance (third patient); and manifestly altered as in the third

case. The recipient organisms were normal as in first case, apparently normal as in second case, distinctly diseased as in third case. By combining these different elements our grafts paved the way to the following eventualities:—(1) Graft of normal thyroid substance in a normal organism; (2) graft of thyroid tissue manifestly altered in a normal organism; (3) graft of thyroid tissue apparently but slightly altered in an apparently normal organism; (4) graft of normal thyroid tissue in an organism clearly diseased; (5) graft of manifestly diseased thyroid tissue in a manifestly diseased organism; and (6) graft of slightly changed thyroid tissue in a manifestly diseased organism.

Six months later I removed from the first patient, the girl, one of the grafts made with her own thyroid (first eventuality). Two months later we removed from the lad, our second patient, grafts from the third patient (sixth eventuality); and fifteen months after we removed from the last-mentioned grafts of her own thyroid (third eventuality). These fragments were subjected to histological examination with the following results:—

*Normal Thyroid Graft in Normal Organism.*—Microscopical examination of this graft demonstrated that the neo-thyroid organ possessed the same structure as the original gland. The alveoli were large, within proper limits, and were filled with colloid substance. Vascularisation was normal, and the neo-vascular formations presented the appearance of stability. No trace of infiltration such as one meets with in young grafts nor of the degeneration or atrophy met with in grafts which are undergoing absorption. We found, in short, that a thyroid graft of normal gland in a normal organism, six months later presented all the appearances and characteristics of normal thyroid gland.

*Graft of Slightly-Changed Thyroid Tissue in an Apparently Normal Organism.*—When the graft was made the tissue did not present a normal structure, there being obvious, though not very advanced, lesions, e.g., dilatation of the follicles, resulting in some parts in coalescence of the alveoli. The grafts were taken from the periphery of the organ and included fragments of the capsule. Removed and examined fifteen months later, its structure presented a closer resemblance to normal thyroid gland than did the original graft, but in the adult alveoli some epithelial buds were seen similar to those met with in grafts undergoing development or hypertrophy. We find then that thyroid tissue which is distinctly not normal but does not present grave structural changes may, when grafted, not only give birth to neo-thyroids capable of persistent vitality, but may undergo a process of progressive metamorphosis which tends to bring back the changed thyroid structure to that of the normal gland.

*Graft of Slightly-Changed Thyroid on a Manifestly Diseased Organism.*—The graft was two months old, and presented a frankly thyroid appearance, but the alveoli were small and contained comparatively little colloid substance. There was some inflammatory infiltration in the perialveolar connective tissue which, however, did not differ from that often met with in experimental grafts performed under normal conditions. In any event it was noted that the grafted tissue had undergone certain modifications, and, as in the preceding observation, in the direction of restoration to the normal gland structure.

It should be added that in this case the recipient organism, in spite of the large number of grafts (seventeen, of which eight were taken from the pathological thyroid, which probably all underwent atrophy), had not received the quantity of thyroid tissue necessary to the proper discharge of the function. The relatively less vitality of the grafts in this subject may possibly be explained by the myxœdematous state of the tissues, which diminished their aptitude to nourish the implanted tissue, and also to a sort of overstrain of the young grafts imposed before they had undergone complete development. Nevertheless, both mentally and physically, the subject, last seen upwards of three years after the operation, presented a remarkable improve-

ment. He had grown and his intelligence was markedly greater.

The grafts of manifestly-changed thyroid tissue in an apparently normal organism (second eventuality), and grafts of the same manifestly-changed tissue in an obviously diseased organism (fifth eventuality), could not be identified two months after implantation. Admitting that the discovery of these grafts presents considerable difficulty, so that it cannot be positively asserted that these grafts had actually undergone absorption, their disappearance in both these observations—the enfeebled vitality of the engrafted tissue and its obviously pathological structure—render this hypothesis plausible.

By grouping the facts just stated we justify the conclusion that thyroid grafts are possible in man, and that by this means we can obtain permanent neo-thyroid glands. The results from an anatomical point of view are excellent, provided normal gland be employed; they are positive even when moderately changed gland substance is employed as in cases of slight goitrous degeneration. They are negative, on the other hand, when obviously diseased gland is used, and further observation will be required to establish within what limits goitrous tissue may be employed with this object in view.

From a clinical point of view we may conclude that the preventive thyroid graft, that is to say, a graft made in cases where, after too radical extirpation of the organ, the subject is threatened with cachexia strumipriva, may avert the impending manifestations. In idiopathic myxœdematous hypothyroidea grafts are equally apt to develop and persist, provided always that the tissues employed have not undergone too marked changes.

In the present state of our knowledge it would be imprudent to dogmatise upon the clinical value of this procedure, which will only command general assent after years of observation in numerous similar cases. But since experiments on animals show that the thyroid organ, when it persists with its normal histological characters, is perfectly capable of fulfilling the function, there is no obvious reason to question the probability of a similar result when it persists in man.

Thyroid grafting, then, deserves to be withdrawn from the obscurity into which it has been allowed to fall, for, carried out with due regard to technical requirements, it may once again acquire a position among thyroidal medications, among which, indeed, it is quite possible it may one day occupy a foremost place.

Our researches, so far as they go, authorise the hope that we may be enabled to simplify the procedure so as to place it within reach of practitioners in general. We are working with the two-fold object of avoiding the transplantation from body to body, a manoeuvre which is not free from drawbacks, and to facilitate the implantation by depriving it of the character of a surgical operation.

With the object of avoiding the immediate transplantation of the organ from the donor to the recipient we have investigated the preservation of thyroid tissue in various liquids and, so far as they go, these researches tend to show that this preservation, at any rate in respect of the thyroid of the rat and the rabbit, is possible in artificial serum and in the blood serum of certain animals, but only for a comparatively short period of time (rather under an hour instead of ten seconds in the air). Our latest observations justify the inference that ere long it may become possible to prolong this period in a marked degree.

With regard to the simplification of the implantation we propose, at M. Kummer's suggestion, to intercalate portions of thyroid gland without the necessity for cutaneous incision. Thyroid tissue, reduced into very small fragments, by the aid of a sharp knife and with every precaution to avoid crushing, which would destroy its vitality, may, so to speak, be emulsified in the preservative liquid and injected into the selected organism through a trocar or large hollow needle. These experiments, which are still in progress, have not as yet given results sufficiently conclusive to allow of our formulating a definite conclusion. In any event,

it is evident that if we are successful in rendering this procedure practicable the operation of grafting will become hardly more complicated than an ordinary injection of serum.

Whatever be the future of this procedure it is not to be supposed that it will ever absolutely take the place of palliative thyroid medication. Not only does the latter method of treatment remain indicated in cases where grafting is impracticable, but it may be required as a preliminary step to grafting, in order to prepare the soil, in presence of grave disturbances of nutrition, and indirectly to assist in the development of the transplanted thyroid tissue by avoiding the risks inherent to too early and exaggerated functional demands.

#### GREAT NORTHERN CENTRAL HOSPITAL.

Medical Cases under the Care of H. W. SYERS, M.A., M.D.

CASE I.—A boy, *æt.* 9.—The history was that the child had been in his usual good health until ten days before he was brought to the hospital. At that time he was somewhat indisposed, but the symptoms were mainly those of gastric derangement and caused no anxiety. His skin was noticed to be rather hot when put to bed just nine days before he was seen, and he slept badly. Next day, on rising, it was found that the right upper extremity was paralysed. He was unable to move the limb at the shoulder-joint in any way whatever, and, in fact, the only movements which could be effected were those of pronation and supination of the fore-arm, together with flexion and extension of the fingers. The febrile symptoms rapidly disappeared, and nothing abnormal remained except the loss of power already described. The sphincters were not affected, and no pain was complained of, except some slight discomfort in the affected limb and trifling stiff neck on the right side. The child was somewhat pale, but fairly nourished. The right upper limb hung quite helpless at the side of the body. There was not the smallest power of moving it at the shoulder or elbow-joint. The muscles of the fore-arm generally were soft and flaccid and were apparently slightly wasted. The grasp of that hand was almost *nil*. Sensation was perfectly normal all over the paralysed limb. No response could be obtained from the elbow and wrist taps. The lower portions of the trapezius and the serratus magnus muscles were also affected, and the angle of the right scapula was unduly prominent, especially when the limb was lifted up above the head. There was no evidence of loss of power in any muscles other than those referred to. The gait was perfectly normal, and all movements could be performed, both as regards the left upper extremity, the trunk and the lower limbs, yet the knee-jerk was absent on both sides. The affected limb was very slightly colder than that of the opposite side. No vaso-motor changes could be made out.

Dr. Syers pointed out that all the muscles supplied by the brachial plexus were to a greater or lesser extent involved, and he diagnosed the case as one of anterior poliomyelitis, in which the symptoms were limited to one limb, and that alone. Such cases, he remarked, were decidedly rare, as in the great majority of instances the malady selected certain muscles or groups of muscles, passing over others, and also involved more than one limb, being sometimes of a hemiplegic type, or affecting one lower extremity and the upper limb of the opposite side.

CASE II.—The patient, a boy, *æt.* 6, was brought to the hospital with the following history:—He had been in good health until about a week before being seen. At that time, and without apparent cause, he first complained of pain in the abdomen, chiefly about the umbilical region. The pain was not increased on pressure, and, as far as could be gathered, was of a colicky nature. There was slight diarrhoea, the bowels acting two or three times a day, and there was loss of appetite. There was no cough, and no history was

given of any symptoms pointing to chest disease being present. The condition remained the same, constant gripping pain being complained of, until the patient was brought to hospital.

The child was well grown and well nourished. A most careful examination of the abdomen revealed no abnormality whatever; the wall of the abdomen was flaccid, and nothing in the nature of a mass could be felt anywhere. It was obvious that the mischief was not situated in the abdominal cavity, and the facial aspect was strongly indicative of thoracic disease. The face was somewhat dusky, the *alæ nasi* moving slightly during respiration, and the child was distinctly short of breath. Physical examination revealed the fact of the presence of a considerable pleural effusion at the right base, where there was marked dullness on percussion, and the breath-sounds, though by no means lost, were yet distinctly more feeble than on the left side. The temperature was 101°.

Dr. Syers remarked upon the great importance of this case. He emphasised the fact that the history and symptoms are not infrequently most misleading in the case of young children, and the present case proved this in a very marked fashion. Everything in the history of the child's illness pointed to the lesion being situated in the abdomen, and there was absolutely nothing to lead to the suspicion that the case was one of pleural effusion. The practical deduction to be drawn from this case was pointed out by Dr. Syers, and it was that never, under any circumstances, should an examination of the whole of the organs and systems be neglected, and this especially in children. If this be not done, disaster will certainly ensue either sooner or later.

The tendency of symptoms to be referred to a distance is by no means unusual in children, and this should ever be borne in mind. It was found that the right pleural cavity was practically filled with clear fluid.

CASE III.—The patient, a boy, *æt.* 6. His illness had commenced a year and a half before being seen. The first symptom was a weakness of gait and a tendency to stumble. This had continued, and had become more marked. In other respects the child had remained in his usual health. There was no family history of nervous or other disease.

The child was rather pallid, but not unhealthy-looking. His gait was peculiar; the legs were widely separated, and in walking he swayed from side to side, the movements of progression being feebly performed. The upper limbs were quite healthy, all their movements being normal. The muscles of the lower extremities, with the exception of those of the calves, were considerably wasted and flabby. This was especially marked as regards the thigh muscles. The knee-jerks could not be obtained. The calf-muscles were considerably increased in size, and were abnormally hard and firm to the grasp. The increase in size was quite obvious, even on superficial examination.

Dr. Syers pointed out that the case was an instance of that rare malady, pseudo-hypertrophic paralysis. He called attention to the wasting of the muscles of the lower extremities, with the exception of those of the calves, and remarked that the diagnosis would be confirmed by placing the child on the ground and observing if he assumed the erect posture in the manner which is so characteristic of this disease. The child was placed flat upon the ground, and the manœuvres which are decisive of the existence of pseudo-hypertrophic paralysis were carried out in a perfectly typical manner.

### British Health Resorts.

#### VI.—MULLION (CORNWALL).

[BY OUR SPECIAL MEDICAL COMMISSIONER.]

MULLION has long been prized by the favoured few as one of the most delightful of Cornwall's many charming health and holiday stations. Through the enter-

prise of the Great Western Railway it has now been rendered easily accessible. Mullion is situated on the eastern side of the famous Mount's Bay, that great natural recess on the southernmost boundary of "The Delectable Duchy." The nearest railway station is Helston, some eight miles distant. The drive from Helston to Mullion along Cornish lanes crowded with a rich and varied flora is peculiarly attractive. An omnibus runs between the two places, and now travellers may journey rapidly and comfortably by motor car.

Mullion is a simple little rural district, picturesque and peaceful, offering opportunities for a "rest cure" particularly needful for the jaded brain-worker and wearied town-dweller. It is an ideal resort for the recuperation of brain and nerve. Convalescents, invalids and delicate adults will here find much that is healing and health-reviving.

Climatically, it offers many advantages. In winter the climate is exceptionally mild, due, doubtless, in great measure to the influence of the Gulf Stream. In summer, invigorating breezes supply a bracing character which is absent in many of the southern resorts of the county. We have been favoured with special meteorological returns of the district taken in 1899, from which it appears that the average temperature in winter is 46° 89', in spring, 52° 34', and in summer, 59° 92', the mean daily range for the whole year being 9° 29'. In the winter, November to February inclusive, 290° 6 hours of sunshine were registered; in the spring, March to June, inclusive, 871° 39 hours; and in summer, July to October, inclusive, 941° 52 hours. The total rainfall is given as 28° 61 inches; 15° 32 in winter; 5° 67 in spring; and 7° 62 in summer.

Mullion offers many delights for the artist and naturalist. Admirable golf links are near at hand. The vigorous will find ample opportunities for sea bathing, boating, sea fishing and other sport. The neighbouring country is well suited for driving and cycling, and offers endless charms for the pedestrian.

In the immediate neighbourhood there are numerous attractions. The district is particularly fine in its natural rugged sea-coast outline, the cliffs are bold and imposing, and the grandeur of the rolling sea will forcibly appeal to many. The psychological influence of this district should be known to physicians. There are many cases needing the mental stimulus which Mullion can so well supply.

This is not a resort for the fashion-loving invalid, but a peaceful retreat for Nature's true lover. The visitor needing constant medical attention will choose some well-known spa or journey to a much-advertised town resort; but the patient requiring simply a hygienic environment and restful mental life will find all that can be desired in this somewhat isolated land of enchantment in the Lizard.

The visitor will obtain excellent accommodation at the Polurrian and Poldu Hotels, both admirably conducted under the same management. The former is situated immediately above Polurrian Cove, from whence good views of Mullion Island may be obtained. The island is of much interest to geologist and ornithologist. Poldu Hotel is situated on the cliffs within sight and sound of the invigorating sea. It is of modern construction and peculiarly fitted for those desiring to live in accordance with strict hygienic methods. It is well designed for patients requiring to follow "open-air" procedures. The Mullion Cove Hotel is situated immediately above Mullion Cove, and is quite modern. A limited number of apartments may be obtained in the adjacent village of Mullion Church Town.

Medical practitioners needing relaxation and change from the routine of the daily round of professional fatigue and anxiety may well turn to this unspoilt and altogether unsophisticated district of Cornwall's most fascinating land; and to it they may safely send many of their cases for mental rest and physical recreation.

THE total number of small-pox patients under treatment in Belvidere Hospital Glasgow, in the middle week was twenty-three.

## France.

Paris, August 14th, 1904.

### TREATMENT OF RENAL INSUFFICIENCY.

PROFESSOR TEISSIER, of Lyons, treating the question of opotherapy in renal insufficiency, renders testimony in a remarkable article to the value of such means in the therapeutic treatment of uræmia, and reviews the means employed to aid the weakened renal function and to replace the *role* of the suppressed internal secretion. The study of these measures is interesting not only as to the variety of their mode of action, but also as to the light thrown on the extent of the therapeutic effect and on the indications for treatment.

Teissier speaks first on the effect of the glycerine extract of the kidney employed in subcutaneous injections for the most painful complications of renal insufficiency—dyspnoea, uræmic cephalalgia, and gastrointestinal troubles. The benefits obtained from this treatment were such that frequently the patients prayed that the injections should not be suspended. It might be asked, he adds, what were the motives which retarded the diffusion of a method which, after all, was easy in application and inexpensive? The reason was, perhaps, that the treatment was only suggested when the nephritis had arrived at the ultimate phase of its evolution. Glycerine extract did not have any pretension to regenerate the parenchyma destroyed, its introduction into the economy exercised but very slight action on the glandular functions, and should not be considered as possessing a real curative effect. But by its means, the disorders caused by the toxic substances or retention can be checked temporarily, until the kidney, becoming more permeable, will allow them to filter through it.

The second means indicated by M. Teissier is the injection of a certain quantity of the serum drawn from the renal vein. The serum employed was drawn from the vein of a goat at the Veterinary School of Lyons, and employed systematically during the last four or five years.

In one case of scarlatina, the patient was taken with all the symptoms of uræmia, abundant albumin, cylindrical casts, headache, vomiting, &c.; death seemed imminent. An injection of five drachms of serum into the right flank produced a kind of resurrection the same day, and in three or four days afterwards the patient was convalescent. The casts had disappeared, and the urine reached three quarts in the twenty-four hours. Several cases cited in the thesis of Lignovolle proved the powerful effects of this treatment. The injection is well tolerated, but frequently provokes a considerable rise in the temperature. The effects are very rapid. The vomiting, dyspnoea, and headache become alleviated in a few hours in spite of the febrile reaction, while the albumin diminishes in quantity and the diuresis increases considerably, with immediate decrease of the toxins.

The third method employed to aid the functional insufficiency of the kidney consists in directly utilising the pulp of the raw kidney, as recommended by Prof. Renaud, of Lyons, and of which a full account has already appeared in THE MEDICAL PRESS AND CIRCULAR. This method, it will be remembered, consisted as follows: Two fresh pork kidneys were cut up fine and thoroughly washed so as to remove all traces of urine. They were then pounded into pulp, and a pint of cold salt water (a teaspoonful of salt) poured over them. After macerating four hours, the liquid was decanted, and the patient drank it in four or five doses in the day,

mixed with some vegetable soup (*soupe julienne*), each day for ten days, fresh kidneys being procured. This treatment certainly gave good results, but very many patients could not overcome their repugnance to it and it had to be suppressed. M. Teissier thinks that this trouble might be avoided by substituting dry preparations of the organ, presented in the very practicable form of lozenges, as prepared by certain intelligent chemists, and if the medical attendant felt some hesitation in employing them, he could always have recourse to the glycerine extract, a method much more easy in its application than injections of serum of the renal vein.

In concluding, Prof. Teissier says that renotherapy, systematically applied and continued, appears particularly indicated in patients suffering from mixed or parenchymatous nephritis. As to the preparations mentioned, the physician will choose the one best adapted to his patient. If he will bear in mind that the method is not to be regarded as absolutely curative but as an adjunct of considerable value to other means, he will experience but little difficulty in employing it. When he uræmic complications have subsided it is frequently useful to inject daily for ten or fifteen days small doses (a Pravaz syringe) of the nephrin.

### Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, August 15th, 1904.

#### ELEPHANTIASIS CONGENITA.

At the meeting für Innere Medizin, Swoboda related the history of four cases of congenital elephantiasis, two of whom he exhibited.

Escherich asked if he had applied the Röntgen rays to all or any of these cases, as he had often found lymphangioma in the internal organs.

Hochsinger thought that the two cases presented to them had all the appearance of hypertrophy of the osseous structure, particularly in the lower extremities, where the tibia showed undeniable signs of exostosis, as the surface of the bone was very irregular. The Röntgen rays would be very instructive in these cases.

Swoboda replied that he had applied the Röntgen rays purposely for the bones, and found no changes in these structures.

#### PNEUMOTHORAX—RECOVERY.

Schrötter gave the history of a case of pneumothorax which had arisen in consequence of the presence in the lung of circumscribed tubercle. The patient was *æt.* 17, and had developed the morbid condition without any symptom of adhesion, although the lung was retracted at the hilus of the right side. In order to develop the lung, Schrötter practised the "biparietal" method of pressure internally and aspiration externally. He punctured the pleura and by a system of pressure bottles forced oxygen into the vesicles of the right lung, while extracting the air from the pleura, and in order to keep the lung in this distended condition he plugged the right bronchus with a firm tampon, thus holding the lung firmly distended. The tampon was attached to a fine silver catheter, which lay in the mouth and trachea, and could be withdrawn at will.

At the first sitting, when tapping the pleura, 2,200 cubic centimetres of air were extracted from the pleural cavity, which allowed the mediastinum and heart to return to their proper position, and vesicular breathing could be heard over the lung. After this the frequency of the respirations fell from thirty to sixteen per minute, and with more comfort, as the patient could now recline in sleep. Radiography showed a greater

volume of lung to the right of the middle line, though not complete. At the second sitting 500 cubic centimetres of gas were extracted, and an equal amount of oxygen injected through the catheter and tamponed as before. After this operation the Röntgen rays showed the pleural space quite filled except a small portion at the base and apex.

To accomplish the full expansion the oxygen was repeated till the full tension was acquired and all the air expelled from the pleura.

Both of the major operations were unattended by fever or any other disturbance.

#### AMÆBOID ENTERITIS.

Vollbracht showed a patient with a few preparations of amœba which he had taken from the fæces.

The patient was a waiter, *æt.* 20, and was always healthy till August, 1903, when he was suddenly attacked with severe pains in the abdomen which brought on diarrhoea that lasted three days. After this time he had two or three watery stools daily, for which he went to the local hospital about the end of the year, where he was greatly improved and left. Eight days after his return home the watery stools recommenced, accompanied with blood this time. He again returned to hospital, where he remained a month, but left having made little or no improvement.

In March, 1904, or eight months after the first appearance, he came to Vienna. According to the history elicited, the patient had never been beyond the confines of Lower Austria, nor had any similar complaint been known in his neighbourhood, borne out by local medical testimony. The microscopic examination of the stools offered nothing unusually striking in the fæcal parts, but the mucoid portion revealed a large number of pus cells as well as swollen epithelial cells, bacteria, and many amœbæ. The latter resembled in size, morphology, movement, and general behaviour those described by Loesch as amœba coli, which incorporate red blood corpuscles. Vollbracht then reviewed the history of dysentery, and thought that the labours of Schaudinn had done much to clear up the pathology of dysentery. He discovered two kinds of amœbæ, one benign and the other malignant. The former agreed with the amœba described by Loesch, which he named "Entamœba coli of Loesch," while the other, which attacked and destroyed the tissues, he termed "Entamœba histolytica."

These, according to Schaudinn's opinion, are the true pathological causes of tropical dysentery. The principal difference between these two amœbæ are that the former is fissiparous, the other gemmiparous, in reproduction. The vegetation of the histolytica has been followed on animals with the same result.

Schaudinn experimented on eight animals with the entamœba coli and failed to obtain the characteristic results of the second, although morphologically the two amœbæ are the same, though they may differ in their behaviour through the different functions of the nucleus and ectoplasm.

When the same experiments were carried out with the entamœba histolytica the characteristic action was immediately apparent within a few hours. The amœba rapidly increased, the mucoid tissue was quickly destroyed, and the life of the animal sacrificed within a very short space of time by the ravages of the protozoon.

#### CONGENITAL MUSCULAR DEFECTS.

Neumann, as well as Vollbracht, exhibited a few cases of congenital malformation in the muscular apparatus. One of Neumann's cases had complete absence of the right pectoralis major, minor, and

partial defect of the left, besides a very rudimentary 'formation' of the ancillaris. In spite of these defects the patient was able to carry on work as a washer, and moved the right arm with as much freedom as his left. The strength of the one arm was as powerful as the other when tested with the machine, as the development of the brachial muscles testified. The adduction of the right arm was very little less than the left. Notwithstanding this functional activity he obtained military exemption.

The etiology was congenital, but no defect of any kind is to be traced in the family history. The mother testifies to the flat side of the chest after birth.

Völlbracht had a similar case to this with the absence of the serratus major in addition, who could perform ordinary labouring work.

## Hungary.

[FROM OUR OWN CORRESPONDENT.]

BUDAPEST, August 13th, 1904.

It is always an event in the Hungarian medical world when a new work is published, which is not to be wondered at, considering the fact that most of the Hungarian doctors only speak German, and, consequently, read the much cheaper German medical books. Lately, three new works have been published in Budapest: the first one is the "Clinical Pharmacopœia," edited by Dr. Miller Vilmos, whose name is as well known in Hungary as in Austria, since he initiated the inoculations against tuberculosis with the Marmorek serum. His book comprises the prescriptions of the Budapest clinics. Instead of writing praises about the book, I shall quote a few prescriptions of standard value:—

Prof. Korányi prescribes for appendicitis opium suppositories, a liquid diet, rest, ice-cold lemonade, champagne. After cessation of the acute symptoms, the diet may again be as before. For the promotion of resorption, Preissnitz fomentation, brushing with tincture of iodine, or with the following mixture:—B. Icthyol sulfammon., 5.00 grs.; collodii flexilus, 15.00 grs.

In cholelithiasis Prof. Korányi prescribes, besides a Carlsbad cure, the following formula:—B. Ennatsol (oleic acid soda), 10.0 grs.; tinct. valerian. æth., 5.00 grs.; aq. menth. pip., 180.0 grs.; essent. ananas, 2.00 grs. M.; four tablespoonfuls to be taken daily.

The book has interesting chapters also on pediatrics, gynecology, surgery and the other main branches of medicine. The preface is written by Prof. Korányi.

Hr. Doktor Sándor has revised the obstetrical manual of the late Prof. Kermárski Tivadar, whom he greatly respected as his teacher and loved as a friend. Kermárski's book is well known both in Hungary and Austria, but Kermárski himself is well known beyond these two countries. His clinic embraced and welcomed many foreigners because, having been built up in 1901, it is one of the handsomest institutions of the world, built and arranged after the best clinics on both sides of the Atlantic. The book is considered an able work, many parts of it having been re-written by Dr. Sándor, whose pen and knowledge have been put at the service of even non-medical papers.

Every page of the book, besides showing the strictest science, is a proof of the grand estimation he has for his principal. The book is adorned with Kermárski's photograph, and two pages are devoted to the biography of Kermárski. He was for thirty years the teacher of obstetrics. He learned his art in

Budapest, Berlin, Paris and London. Among his foreign teachers he was fondest of Spencer Wells and Baker Brown, and the impressions which he brought back from England left traces on his whole working and function.

Hr. Doktor Sándor has done really a very appreciable work in undertaking the republication of this renowned work.

The third work which I desire to report is Dr. Rona Sámuel's work on sexual diseases. Prof. Rona is also well known beyond Hungary, for he has been constantly present at Congresses held, not only on sexual diseases, but also on other branches of medical science. His book is full of practical information based on a very large hospital practice, so that his cases outnumber those of any Vienna clinic. Prof. Rona begins his work with an historical review of syphilology, upon which he has bestowed very careful attention. A special feature of his book is the novel method of dealing with the subject from a sociological point of view. In every chapter allusions are made to internal and constitutional diseases which may be associated or accompanied by venereal diseases.

It is really a pity that our able works can be read only by a few million people, as the Hungarian language can be read by only ten millions.

## The Operating Theatres.

### NORTH-WEST LONDON HOSPITAL.

AMPUTATION AT THE HIP-JOINT FOR SARCOMA OF THE FEMUR.—Mr. THOMSON WALKER operated on a woman, æt. 27, who had been admitted for a swelling of the right knee. Fourteen months before admission the right knee was noticed to be enlarged. There was no history of injury, and she had not suffered from rheumatic or other joint disease. The family history was unimportant. The knee continued to enlarge very slowly, in spite of local rest and counter-irritation. It was painless; there was no tenderness on palpation or movement. Two months before Mr. Thomson Walker saw her, she went to the seaside, and the knee began rapidly to increase in size. Dr. Moorhead, of Bridge, then asked Mr. Walker to examine the patient with a view to operation. On admission to the hospital the following condition was found: The patient was healthy-looking and well-nourished, there was a large swelling of the right knee, which consisted of a rounded prominence on the inner side and an obliteration of the outlines on the front and outer side. Only a slight degree of flexion was possible. The patella could be felt on the front of the mass and was movable. The skin was unchanged. The mass was firm and in places hard, and careful palpation showed that it was connected with the lower end of the femur, the upper end of the tibia being apparently unaffected. Although parts of the enlargement were of almost bony hardness, no egg-shell crackling could be felt. Fluctuation was not detected, and there was no tenderness on palpation. The lymphatic glands in the groin were not palpable. A diagnosis of periosteal sarcoma of the lower end of the femur was made, the points considered important in diagnosis being: the size and asymmetry of the swelling, the varying consistency of the growth, and the extreme hardness of parts of its surface, and its connection with the femur. The absence of aching or pain and of egg-shell crackling, the rapid growth, and the peculiar outline were the points in favour of periosteal as compared with endosteal sarcoma. An X-ray photograph showed the shadow of a large rounded mass connected with the inner condyle of the femur

the circumference of this shadow showed an appearance like spicules of bone radiating from the centre. Amputation at the hip-joint was performed. The method used was that known as the anterior racquet incision. The femoral vessels were first exposed by a vertical incision commencing over Poupert's ligament. The artery was first ligatured in two places, and subsequently the vein; these vessels were then cut across; some venous bleeding, owing to a high junction of the deep femoral vein, gave a little trouble. The incision was then carried across the inside of the thigh, four inches below the genito-crural fold, then round the back of the thigh and passed round the outer side, three inches below the upper border of the great trochanter. No further bleeding of importance occurred. There was a little difficulty in the actual disarticulation of the head of the femur, but by freeing the great trochanter and by external rotation and flexion of the limb this difficulty was overcome. A drain was inserted reaching to the acetabulum and protruding from the lower end of the antero-posterior wound. The principal feature of this amputation, Mr. Walker said, was the control of the hæmorrhage by ligation of the main vessels at the commencement of the operation; this, he pointed out, dispenses with the use of a tourniquet, which is difficult to keep in position in this situation. The operation of Furneaux Jordan's, he said, was that usually recommended at the present time, but the operation he (Mr. Walker) had just performed appeared to him to have many advantages in a case such as the present one, especially with regard to the control of hæmorrhage. Furneaux Jordan's method of amputating through the thigh low down and then shelling out the femur, he pointed out, is that usually recommended at the present time for disarticulation at the hip-joint. The grounds on which this preference is based are the slighter degree of shock and easy control of the hæmorrhage, the position of the drainage-tube on the outer side away from the genitals and anus, and the longer and more mobile stump. The amount of shock in the case Mr. Walker had just operated on was not great, and he doubted if it would have been less by the Furneaux Jordan method. The easy control of hæmorrhage he thought the special feature of the anterior racquet method. The preliminary ligation of the femoral vessels relieves the mind of the surgeon at once of any anxiety in regard to hæmorrhage, and permits of rapid completion of the operation. The sciatic artery is very small at the point at which it is severed, and the gluteal vessels are not disturbed. The lower angle of the antero-posterior wound, he considered, was an ideal position for drainage, and this is not so near the anus that ordinary care cannot prevent soiling of the wound. There was no advantage in his mind in having a longer stump if it carries no bone. If an artificial limb can be fitted at all it will, he thought, be as useful on the stump of an anterior racquet amputation as on that of a Furneaux Jordan's. The former method, therefore, appeared to him to be preferable in cases like this when the hip-joint is not diseased. The prognosis in a case such as this was somewhat doubtful. Some slightly enlarged glands were found in the groin during the amputation, but under the microscope they contained no tumour cells. Microscopic examination of the tumour showed a few giant-cells, and these are usually considered to represent the slower-growing and less malignant endosteal sarcoma. It is not, however, certain, he said, that the presence of these cells is distinctive, and the absence of expansion of the bone and the other characteristics led him to believe that the original diagnosis of periosteal sarcoma was correct. The prognosis in this case was

therefore less hopeful. After the operation the patient showed signs of collapse, and a pint and a half of saline solution was infused into the left median basilic vein. It was not, however, necessary to repeat the infusion, and the convalescence was uninterrupted. The drainage-tube was gradually shortened and finally removed on the eighteenth day. The temperature rose to 101°, and continued at this level for a week. It then fell and remained normal.

Six weeks after the operation the stump was firm and could be tilted forward by the patient. The scar had contracted lengthwise and lay in the anterior surface of the stump.

“SALUS POPULI SUPREMA LEX.”

WEDNESDAY, AUGUST 17, 1904.

### MEDICAL MEN AND LITERARY COMPOSITION.

THE literary acquirements of medical men, as a broad and general rule, are notoriously wanting in the essentials of good craftsmanship. As with their handwriting, good matter is spoiled and unreadable because of the defective methods of expression. In this way many a skilful surgeon and many a learned physician fail when they endeavour, pen in hand, to convey to others the knowledge gathered from wide reading and long experience. On the other hand, not a few of the names that have become household words in the history of the profession owe their pre-eminence in no small degree to the possession of a sound literary style. Yet the elementary principles of English composition are easy of acquisition, and, so far as that goes, should be included in the scope of every liberal education. The fact of the matter appears to be that medical men are so engrossed in the practice of an exacting profession that they have little leisure or inclination for the art of letters. For all that, the busy practitioner will find both relaxation and profit in the study of English composition. He will find an admirable essay on the subject, compact with valuable information, in a little book recently published by Professor Clifford Allbutt under the title,

"Notes on the Composition of Scientific Papers." In the course of each year the author is called upon to peruse some sixty or seventy theses for the degree of M.B., and about twenty-five for that of M.D. "The matter of these theses is often excellent, but their prevailing defect is such as to obscure, to perplex, and even to hide or travesty the sense itself. Meritorious in substance as these productions may be, they are, as they stand, unfit for the printer." This picture will be recognised by editors of medical journals as representing the attitude of the average contributors. It is not merely such disfigurements as the split infinitive and the misplaced "only" that offend his eye, but also the frequent occurrence of errors of grammar and of offences against the elementary rules of composition. The misuse of relative pronouns is a fruitful cause of confusion. Dr. Allbutt's illustration from a recent thesis runs thus:—"He said to his patient that if he did not feel better, he thought he had better return to say how he was." The ambiguities remind us of the well-known examples, "No one had yet demonstrated the structure of the human kidneys, Vesalius having examined them only in dogs." The author's rule in this particular case is admirable: "On the revision of a manuscript, pause at every such pronoun till you are sure that its particular antecedent is unmistakable." False concords are plentiful as blackberries in ordinary medical manuscript, as, for instance, "The shame and pain to which his failure expose him"; "Nothing but his poverty, modesty and diffidence prevent"; "Neither of these boys were remarkable"; "Of these persons none (no one) were robust." An amusing error, often committed even by good writers, is that of the intrusive "not." The complete logical subversion of meaning that may be thereby caused is shown in the following sentences: "I ran to see if I could (not) get a seat"; "Let us see if we can (not) help him"; "I cannot say what disease she may (not) have"; "Mr. Jones asked if both lungs might (not) be diseased." An extremely common inelegance among unpractised writers is the use of short suspensions within larger periods: "To improve, as much as possible, the general health, &c.," would read better by changing the position of the two clauses. "He made many sketches of, and gave close attention to, the village churches of the county" diverts the emphasis to the unimportant words "of" and "to." A more correct and logical rendering would be, "He paid close attention to the churches, and made many sketches of them." Neglect of the proper order of words leads to numberless comical effects, as: "They followed the party step by step through telescopes"; "Ford's theatre is for sale where Lincoln was assassinated for religious purposes"; "A clever magistrate would see whether he was lying a great deal better than a stupid jury"; "I understand that when he died Cardinal Mezzofanti spoke at least fifty languages." This book of Dr. Allbutt's is stuffed from cover to cover with information of interest and of

practical importance to all members of the medical profession who wish to reduce their thoughts, wishes, aspirations or experiences to literary form.

#### HOLIDAY EXERCISE.

At this season of the year, when every town-dweller to whom the opportunity presents itself makes for the country or the sea-side, the question of appropriate exercise becomes an eminently practical one. A holiday has been defined by advocates of the "strenuous" life as a change of occupation, and to the average man, so long as the change involves an abandonment of brain fatigue, and a substitution of physical for mental exercise, the medical man will not be inclined to quarrel with the definition. It may, however, be well to protest against the attitude of mind of those who consider a holiday wasted unless its precious hours are filled by the pursuit of fresh knowledge and experience. A symposium of opinions of some leading Members of Parliament recently taken by one of the leading morning papers contained the views of several representatives of manufacturing towns, who held that the ideal holiday of a young Londoner was to be found in a visit to some Yorkshire or Lancashire town to study the processes of manufactures carried on there. With all respect for the legitimate desire of men to improve themselves on every suitable occasion, we cannot but think that for a young clerk or business man to spend his short fortnight or three weeks' vacation in an atmosphere of looms and machinery is to court disaster. To all mentally hard-worked men the holiday should be emphatically a period when the mind lies fallow, and when the body is given the chance that it so rarely gets of moderate, healthy exercise. It is obviously foolish for the man whose muscles are flabby and whose circulating and respiratory mechanism is out of tone to attempt herculean feats as soon as the black coat is changed for flannels, and much damage is often inflicted on themselves by enthusiasts who try by means of sudden and violent exertion to get as much "good" as possible out of their holiday. All violent exercise must be preceded by a period of training if the strain is to benefit the system, and for the average vacation the gentle cult of *dolce far niente* is infinitely preferable to fatiguing bicycle rides or exhausting expeditions that tax the powers of endurance of their subjects to the uttermost. Some interesting observations recently made by Dr. Philip Hawk, Demonstrator of Physiological Chemistry in the University of Pennsylvania, tend to show the comparative value of various forms of bodily exercise, and in them the physician may find a scientific basis for advice he may be called upon to give as to the best holiday pursuit for his patients. The method adopted by Dr. Hawk was to examine the blood of athletes before and after exercise, making counts of the red corpuscles with the hæmocyto-meter. His observations showed that the blood of the average college athlete in good training contained

over a million more red cells than that of the average individual, namely, 5,600,000 corpuscles per cubic millimetre, as compared with four and a half or five million. Such an observation is of great value, as it demonstrates the fact that the properly-prepared athlete differs structurally from the untrained man, and that he may therefore be assumed to be capable of deeds that would be beyond the powers of the latter. An ordinary individual, then, whatever his potentialities, should regard himself as being incompetent to undertake feats of endurance or strain without thorough preparation as he would be, say, to appear for his county at cricket without weeks of careful practice at the nets. Dr. Hawk found that the immediate effect of exercise was to increase rapidly the number of red corpuscles in the blood, but that this increase readily fell as the exertion was continued beyond a certain point. He attributes this to the necessity of calling into play numbers of cells that have been accumulating or lying in reserve during periods of inimitable action, and to the rapid depletion of this supply when the demand is sustained. So far his observations are not complete, for he is endeavouring to find out what is the effect on the blood when exertion is continued to extreme degrees, but his results as to the comparative increase of corpuscles under various forms of athletics are suggestive. Thus he found the percentage of gain after a hundred yards' sprint to be 24·8 of the total number of corpuscles, whilst the hundred and twenty yards hurdle race produced a 21·5 increase; the half mile, 17·9; the mile, 13·9; two miles, 8·8; broad jump (after six jumps), 15; three minute water polo game, 27. Here it will be seen that while the short, sharp strains produced a sudden high increase, the more leisurely and longer-continued exertions showed distinctly smaller gains, and examinations on bicyclists and pedestrians confirmed these results, the initial increase rapidly diminishing as the exertion progressed till it disappeared altogether. Reviewing his observations, Dr. Hawk concluded that swimming is the ideal sport. This form of muscular exercise was found to produce an average increase of 21 per cent., as compared with an increase of 16·5 per cent. after sprinting, 12·8 per cent. after walking, and of 12 per cent. attained as the result of bicycling. Short swims, averaging three minutes in duration, produced an increase of 22·5, as compared with 13·9 per cent. found after swims of a quarter of an hour's average duration, during which period the subject was putting out as large a share of activity as possible. This method of Dr. Hawk's for examining the effect of exercise on the organism would seem to be a valuable one, and it certainly teaches the lesson of the unwisdom of persisting in an exercise that is making too great demands on the reserve of corpuscles. We hope he will continue his observations and that these may embrace some tests of athletes, such as Holbein and Weidmann, before and after some of their prodigious efforts. To the plain man, however, the conclusion

is clear, that the holiday should be a time for accumulating a higher percentage of corpuscles and that arduous and fatiguing exercises, far from doing this, will only destroy any reserve that he may be already possessed of.

#### THE TREATMENT OF ACCIDENTAL HÆMORRHAGE.

SIR ARTHUR MACAN'S valuable paper, read before the recent meeting of the British Medical Association, on the subject of accidental hæmorrhage during pregnancy, and the discussion to which it led, may be said to point a moral and adorn a tale that will not perhaps be useless to the coming generations of English obstetricians. The tale is very similar to that related to the Obstetrical Society of London by Dr. Teacher, in his now classical paper on "Deciduoma Malignum," and its burden is that preconceived and settled ideas, when not supported by facts, hinder progress. The moral is, if we may express ourselves in the vulgar fashion, to beware of "cock-sureness." Past students of the London medical schools will remember how a well-known London writer on obstetrical subjects openly stated that he would "plough" any student who told him that in cases of accidental hæmorrhage he would plug the vagina. Many of the same students came to Dublin to learn their midwifery in the Dublin maternity hospitals. They saw there the treatment, which London had condemned, adopted with the result that the mortality of accidental hæmorrhage, instead of being 40 to 60 per cent., as they had been taught, was something between 3 and 8 per cent., and they were confessedly puzzled. The question immediately occurred to them—why should Professor So-and-So in London state that the mortality of accidental hæmorrhage was 40 per cent., and that plugging would kill the patient, when in Dublin the mortality is inappreciable, and the vagina is always plugged? This condition of affairs was the rule ten years and more ago, and yet it is but within the last year or two that the London obstetrical school has come to recognise that dogmatism and truth do not always go together. The London Obstetrical Society laid down that the tumour known as deciduoma malignum was nothing but a sarcoma of the uterus. As a result, the majority of English obstetricians and pathologists took no further interest in the growth. Everything was known about it, the Obstetrical Society had told them so. However, it was subsequently found that the Obstetrical Society had told them wrong. Similarly, with regard to the treatment of accidental hæmorrhage, London opinion laid down three "laws": that the student who suggested the plugging of the vagina would be "ploughed"; that the medical practitioner who used the plug would kill his patient; and that the plug would convert an external into an internal hæmorrhage. The two last "laws" were proved to be wrong, but still the first remained, and as a result the spread of the knowledge of the treat-

ment was delayed, and many lives were sacrificed. At last a change came. The younger generation of obstetricians decided to think for themselves, and to cast off the hereditary shackles by which they had been bound. The Obstetrical Section of the British Medical Association agreed to discuss the treatment of accidental hæmorrhage. The chief active opponent of the treatment by plugging remained away from the discussion; the chief passive opponent confessed that he had always thought well of the treatment, but out of regard for the examination prospects of his students he had refrained from mentioning it; and Sir Arthur Macan's paper was heartily accepted by the meeting. We trust that as a result of the change of opinion the pendulum will not now swing too far in the opposite direction, and cases be treated by plugging for which such a treatment is unsuitable, and so discredit be brought on the method. Plugging the vagina is the best treatment that has as yet been suggested for cases of accidental hæmorrhage in which the patient is not in labour and in which the bleeding is external. It is a useless line of treatment in cases of severe concealed accidental hæmorrhage, unless the uterine wall has commenced to react against a further increase in the uterine contents. It is an unnecessary line of treatment in cases in which the patient is in advanced labour and the uterine contractions are strong. As the present appears to be a favourable time for the upsetting of preconceived ideas, we would venture to suggest that the supremacy of Marion Sims' position in gynecological examinations and operations should be attacked. We think that we are right in saying that England is the only country which still adheres to this position, and that the use of the more generally adopted dorsal position does not favour the occurrence of parametritis, as was recently stated by an English writer.

### Notes on Current Topics.

#### The Administration of the R.A.M.C.

A RECENT writer in the *Westminster Review* has made a discovery which is so good that we desire to reproduce it in his own words:—"The latent talent for administration possessed by the Anglo-Saxon is neutralised in the R.A.M.C. by the Irish and Scotch members who form the bulk of its members. The racial and national peculiarities of these two preclude them from being successful administrators. The excessive vanity of the one and the inordinate conceit of the other are quite antagonistic to that calm discussion, gentle spirit of compromise, and firm perseverance which render pure Englishmen of any rank and any degree of education such wonderfully successful and able administrators and organisers." It seems to us that nothing but a combination of "excessive vanity" and "inordinate conceit" could make anyone so willing to display his ignorance of the nationality of, we think we may say, the majority of the great administrators of the Empire. We would suggest to this "pure Englishman" that his

sentiments should in future be couched in pure English, and that they should be influenced, if not altogether guided, by the dictates of common sense and—truth. Perhaps, however, he is what the Scots call a "puir body."

#### A Post-Dated Medical Certificate.

IT is difficult to imagine any set of circumstances under which the post-dating of a medical certificate could conceivably be prudent and altogether defensible. Certainly not when the document was drawn up to excuse the attendance of a juror at a trial to be held nine days after the date of signature. Yet that is the kind of certificate recently presented to Mr. Commissioner Lawrence, K.C., at Liverpool Assizes. The judge stated it had come to his knowledge that a certificate had been handed in from a Liverpool practitioner to the effect that a certain juror was unable to attend, and post-dated by thirteen days. The reason that had been offered for adopting that course was the fact that the doctor was going out of town, and that his professional skill enabled him to say that the juror would not be able to attend. That was, to the judge's mind, a mode of dealing with the matter that was highly reprehensible, and was a view of the duties of the medical profession which he could not congratulate the gentleman upon entertaining. Judges, he remarked, had been in the habit of treating medical gentlemen as gentlemen who could be implicitly relied upon, and any departure from that course on the part of a member of the profession was not only calculated to injure the profession, but was also a serious offence against the State. We agree that any medical man acts foolishly who tampers with certificates. At the same time, it would be better were the legislature, which expects so much, to pay medical men for certificates on a scale commensurate with the fees enjoyed by the legal profession.

#### Self-Certified Lunatics.

THE judicial view of what constitutes attenuated responsibility in criminals suspected of mental aberration is in startling conflict with that of medico-legists and psychological experts. The judge's directions to a jury in a recent case of murder by an otherwise well-conducted but hereditarily damnable youth, emphasise this divergence of opinion to such a degree that it becomes a *reductio ad absurdum*. He warned the jury against accepting the theory of "uncontrollable impulse," of which, he added, medical men were very fond, and he laid it down that every person was assumed to be sane until the contrary was proved, and that it lay with the prisoner to establish this. But how is a prisoner to prove this except by acting as a lunatic? When a wealthy person indulges in petty theft it is mercifully described as kleptomania, and probably in most instances with due reason. When a previously well-conducted youth commits murder without adequate motive surely he has done all that could reasonably be expected of him to establish his unsoundness of mind. We must confess that we are

unable to understand the dogged resistance of the judicial mind to the medical theory of attenuated responsibility. In murder cases, at any rate, there is no risk of the accused being let loose on society to perpetrate further acts of violence; it is merely a question whether he should be "treated" in prison or in an asylum. Surely the medical man is the best judge of cases suitable for admission to hospital. The fact is, that in presence of purposeless acts, especially if corroborated by a neurotic family history, the assumption ought to be exactly in the opposite direction. It is satisfactory to find that in this particular instance the jury were not led away by the judge's sophisms, and found that the prisoner was insane.

#### Suture of an Artery.

IN the "Annals of Surgery" for July is recorded a remarkable case of suture of the brachial artery, which was so successful that it merits wide publicity. The patient was a boy of seventeen years of age whose upper arm was severely lacerated by a crush from the wheel of a car. The muscular structures of the outer side were torn in various directions and the humerus was exposed to view. The wound was treated in the usual way, but towards the end of the week profuse hæmorrhage supervened. The radial pulse could not be felt, and the whole arm below the wound was cold, dark, and œdematous. Gaston Torrance, under whose care the case was admitted, opened up the wound and found a funnel-shaped ulcer about the size of the point of a pencil in the wall of the brachial artery. At each beat of the heart arterial blood was shot through the aperture, and the patient's condition was one of some anxiety. Torrance attempted to close the opening by suture, but his first attempt made with the arm extended was futile, as the stitch tore out when it was tightened, and the hæmorrhage proceeded with unabated force. He then tried to relieve the tension on the stitch by bending the arm, and the relaxation being secured, he inserted a purse-string suture around the margin of the ulcer with a fine curved intestinal needle. When the suture was drawn together it was found that the bleeding was completely controlled. In order to give added security, a piece of muscle was dissected up and grafted over the anterior portion of the artery. In four hours the pulse-beat was easily perceptible in the radial, and after two weeks in bed and two months subsequent use of a splint, the boy went home with a thoroughly useful limb. Suture of a large artery in its continuity is seldom called for, but this case illustrates particularly well the hopefulness of the method when applied with skill and intelligence.

#### An International Medical Language.

IN these days of international congresses and free exchange of scientific ideas the need for a common language of intercommunication is badly felt. Many praiseworthy and ingenious attempts, from Volapuk downwards, have been made to establish a universal language, but no sooner is a good

tongue invented than along comes another with still greater claims to attention. People consequently become bewildered, and awaiting universal approbation nothing is done. From the point of view of medicine a *lingua franca* is undoubtedly a great *desideratum*. Science has no home and no country, and with the ever-increasing volume of observation and experiment carried on in every land the medical man becomes more and more unable to keep as well abreast of current knowledge as he would wish to do. It seems a thousand pities that Latin has fallen from its place as the recognised medium for medical writings, for not only is Latin the basis of most of the occidental languages, but it is one peculiarly well adapted to the purposes of science. One cannot help noting it as a curious fact that coincidentally with the widening of education and the consequently great diffusion of classical knowledge, Latin has gradually become less and less familiar to the physician of culture. It is doubtful if at this moment 10 per cent. of the Fellows of the College of Physicians could read or write a medical paper with anything approaching facility in the Latin language, and it is quite certain that not 1 per cent. of readers of a medical journal would attempt to decipher it. A hobby of one of our contemporaries is to push the claims of modern Greek as the language for general medical purposes, but, in all sympathy, we fear that their dream will not be realised in our generation. The solution would seem to be a natural one, namely, the adoption by other nations of the language of the race which attains the greatest pre-eminence in the political and scientific world, and we incline to believe that English will eventually prove to be that language. At any rate, it is not likely to be Japanese for another century or two.

#### The Digestibility of White Bread.

IT is not always the medical and scientific journals which single out the various articles of food in turn for the purposes of "attacking" them, as the lay mind loves to think. That they expose adulteration and fraud everybody will recognise, and in this capacity they render valuable aid to the community at large by calling attention to the composition or quality of the different food-stuffs and to the risks of possible contamination which the consumers run when the laws of hygiene are infringed. A certain section of the daily press is apparently fond of adopting the same policy, presumably because it is found that the public are pleased by the admission of medical or rather pseudo-medical details into the columns of their morning paper. A correspondent of the *Times* has recently stated that the present craze for white bread constitutes a danger to the public health. If it be true that the alleged practice of bleaching the flour by means of ozone and nitrous acid, which is said to be adopted by many bakers, is really universal, it might be conceived that the bread baked from such flour might have injurious effects, unless special precautions be taken. All

white bread, however, is not necessarily an "indigestible, non-nutritive food," though the presence of mineral matter or an excess of starch renders it unfit for those possessed of delicate stomachs. The inclusion in the flour of the central portion of the wheat-kernel is generally held to be incompatible with snowy whiteness, but there can be neither rhyme nor reason for sacrificing the phosphates and other nutritive principles merely for the sake of appearance. Many patent breads now on the market, including the aerated variety, are praiseworthy and successful attempts to preserve the nutritive properties of the flour, while combining it with a pleasing appearance. The connection between the consumption of white bread and the prevalence of appendicitis need only be mentioned to be denied *in toto*.

#### Examination of Sputa in Children.

WHATEVER may be the faults and drawbacks of young children, there is one nuisance which they are never guilty of—that is, the spitting nuisance. However fortunate it may be for their fellow-creatures that they do not spread their maladies by expectoration, their medical attendants are sometimes considerably handicapped in making their diagnosis by being unable to obtain specimens of sputum for examination. In suspected cases of early tuberculosis the staining of the sputum is of paramount importance, and delay in the resolution of pneumonias, or the development of some located empyemata, often make the practitioner anxious to check the diagnosis by appeal to the sputum. Several plans have been devised from time to time to obtain expectoration for examination, notably that used by Hirt of passing a stomach tube and collecting the mucus that adheres to it. A simple and satisfactory method has been put forward by Findlay, who learned it from the French hospitals. This consists in covering the finger with gauze and passing it into the aperture of the glottis. The irritation thus excited induces cough, and as the mucus is ejected it is caught on the gauze and reserved for examination. The device is so simple and, withal, so efficacious, that it will be welcomed as a boon by many practitioners.

#### Kyphosis of Muscular Origin.

THE influence of osseous changes in the production of deformities, especially those in which the spinal column is involved, so far outweighs that exerted by other tissues of the body that the possibility of a given malposition being due to causes other than bony is apt to be overlooked. The contractions which appear as a result of paralysis of the limbs are quite familiar, such deformities having their origin in muscular contraction induced by chronic irritation of a nerve-cell or nerve-trunk. Most of the deformities affecting the spine arise from actual changes in the bodies of the vertebræ themselves. With the exception of lateral curvature, alterations of the normal antero-posterior curves of the spinal column are generally due to absorption of the vertebral

bodies from the deposit therein of tuberculous material. The case related by MM. Brissaud and Grenet (a) of kyphosis due entirely to muscular action is, therefore, of some interest. The patient was a man, aged thirty-seven, who had suffered for three years from severe pains in the back, ascribed to rheumatism. He had a regular kyphosis which was less on rising in the morning. The arms were held in semi-flexion. There was no joint-affection, and the vertebræ appeared to be quite normal. The reaction of the spinal muscles to faradism was not diminished, neither was there any reaction of degeneration. The condition was greatly improved by the continuous application of a Sayre's jacket. The observers considered that the case was allied to the condition described by Forestier as "vertebral rheumatism," or rheumatic spondylosis. Similar kyphotic states have also been seen as the result of occupation, as, for example, in vine-dressers. The long-drawn-out antero-posterior curve which occurs as a special type in the aged is sometimes the partial effect of muscular shortening.

#### Inflation in Acute Intussusception.

THE treatment of acute intussusception in young infants still constitutes one of the critical problems of surgery. In spite of the most approved methods of treatment the mortality from this affection remains almost what it was twenty years ago. The best possible chance of recovery appears to be afforded by the immediate performance of laparotomy and actual manual reduction of the bowel. This procedure requires some considerable force, so that the bowel stands in some danger of being torn across. A slight tear, involving only the muscular and peritoneal coats, is not of much importance, as peritonitis is said not to occur under such conditions, but should the mucous coat be lacerated and the lumen of the gut exposed, the matter is far more serious. Rapid resection, if possible, is then the best course to pursue. The other method, that of inflation, whether with fluid or air, is the one still adopted by the majority of practitioners, for it has the advantage of being a less formidable undertaking than abdominal section. Mr. F. J. Steward, (b) of Guy's Hospital, has collected several groups of cases together, showing the results of inflation, and he concludes that this mode of treatment must be regarded as a failure. In the first place, it is unsafe to employ the amount of force which is necessary to reduce the intussusception on account of the danger of rupture of the bowel. If the condition extends higher than the ileo-cæcal valve, inflation must fail, because it has been proved experimentally that the injection of water or gas cannot pass beyond this point. Complete reduction may only apparently take place, which again is a most undesirable occurrence. The greatest drawback of all, perhaps, is that the effects of inflation are invisible, and, therefore, the method is both unscientific and uncertain.

(a) *Nouv. Icon. de la Salpêtrière*, No 2, 1904.  
(b) *Guy's Hospital Gazette*, July 30th, 1904.

The earlier laparotomy be performed in these cases, the more chance will there be of ultimate success.

#### An Alleged Unauthorised Post-Mortem.

It is obviously inadvisable to make a post mortem examination on the body of a patient without having obtained the consent of the friends of the deceased or an order from the coroner. In both cases to act without authority is to invite consequences of a most unpleasant nature. Mr. John Shaw Carleton, a surgeon practising at Newnham, Gloucestershire, has had to appear before the Littledean Petty Session, because he conducted a post-mortem on a body without consent of friends, and in the absence of a direct written direction from the coroner. It appears that he regarded as sufficient authority a letter from the Deputy Coroner directing him to examine the body if requisite, and if an inquest were held. Unfortunately for him an inquest was not considered requisite. The magistrates dismissed the summons, as they did not think on the evidence that a jury would convict. The charge was drawn up in a formidable manner under the Anatomy Act. There were three summonses as under: (1) That he, upon July 25th, being a person lawfully qualified to practise medicine, unlawfully did practise anatomy without having obtained a licence in pursuance of 2 and 3 William IV. c. 75, empowering him to do so. (2) That on the same date, being qualified to practise medicine, unlawfully did examine anatomically the body of John Price without the permission or the direction of the surviving wife. (3) That he did unlawfully carry on anatomy at a place, to wit, the house of Emily Price, there situate, without having given at least one week's notice thereof before the first receipt or possession of the body for such purposes to His Majesty's Secretary of State for the Home Department.

#### Headache Powders.

WITH the medical paragraphs of the ordinary lay newspaper it is impossible to feel the least sympathy. As a rule, they form a sort of compost of sensationalism, of mis-statement, and of false science, dished up by a journalist absolutely ignorant of medicine but wotting well the wants of his public. As a rule the evil done by these slipshod efforts to popularise one of the most highly technical of all sciences is simply incalculable. The only other thing with which it is at all comparable is the crop of disaster sown far and wide by quack advertisements. In that particular, again, with modern lay journalism lies the head and front of the offending. Who can even faintly estimate the total sum of human suffering and sorrow caused by the fraudulent enterprises of curers of kidney disease, of cancer and of a host of other more or less deadly maladies? Curiously enough, the average mind seems always to have a corner open for the quack, even among folk of culture and of position in society. The only item

on the other side of the ledger with which we can credit modern journalism is an occasional crusade against "headache powders" and drug-taking generally. Even such exposures are conducted in a way that must necessarily furnish a great and unnecessary amount of dangerous detailed information to weak-minded readers.

#### An Unpleasant Experience.

THE ways of British administrative law are at times apt to press heavily on the individual, however much there may be to admire in them as a whole. That they are capable of improvement is a more or less self-evident proposition. That view, at any rate, is likely to be held positively by Mr. A. B. Avarne, a Blaenavon surgeon, who recently had a most unpleasant experience of administrative red-tapeism in Cardiff. It appears that his luggage was stolen at the railway station of that town, through which he was passing on his way to a holiday on the Continent. The thief was caught, brought up at the police court next morning, and charged with the offence, and remanded for a week. The whole of Mr. Avarne's kit was contained in the stolen luggage, which the Court took into custody. His very reasonable request that he should be allowed to use some of his clothes was refused by the Bench. This weak point in the administrative law is clearly due to the remand system. If the prisoner had been summarily sentenced or committed for trial, as should have been done, the stolen property could have been restored forthwith to its owner. The remand was doubtless due to the gross injustice of the British law, which seeks to punish a culprit afresh for former offences, and, with that end in view, remands him again and again so that the police may trace his former career.

#### Light Treatment of Small-Pox.

WITH every desire to be fair and to preserve an open mind with regard to new therapeutical methods, it is often difficult to credit the statements that come from even highly reputable quarters as to the efficiency of this, that, or other treatment. A certain healthy scepticism with regard to medical novelties is by no means to be deprecated, and in the interests of the patient who is likely to form the *corpus vile* of the experiment, it is even to be welcomed. The red light treatment of small-pox has been reported on several times from Scandinavian sources, always in glowing terms, and although it is really a resuscitation of one of the crudities of the Middle Ages, the fact that this plan is based on empirism is no valid argument against its adoption if really beneficial to patients. As the treatment of sufferers in what is practically a "dark room" can, at the worst, have but little effect on their comfort and well-being, it is satisfactory to know this method has been thoroughly tried over here. Dr. Ricketts, the Medical Superintendent of Joyce Green Small-Pox Hospital, decided to test its efficiency, and his

experience, published in the Annual Report of the Metropolitan Asylums Board, should settle the matter once and for all. A small ward was set apart for the purpose, the windows being covered with ruby fabric and the ward doors hung with thick curtains of Turkey twill. Illumination was supplied by a red lamp. In this room one or two patients were placed at a time, all of whom were subject to careful selection. Those chosen were in the early papular stage of attacks that seemed likely to run an ordinary suppurative course. In all some twelve cases were treated, in none of which was the development of the stages of the papules in any way different from what might have been naturally expected. Three patients died and several were badly pitted. Dr. Ricketts' reputation for scientific insight and care is a sufficient guarantee that the treatment was accurately and conscientiously carried out, and it may be unhesitatingly pronounced a dead failure. We are glad that the little experiment has been made, as the question may now be relegated to the region of *choses jugées*, and we are left to wonder how such an unlikely wild-cat plan came to gain such a reputation. We can only surmise that what our Scandinavian friends need for the treatment of small-pox is not the light of a ruby globe, but the light of common sense. For the future the doctor's red lamp will be of more service outside his front door than inside the bed-rooms of his small-pox patients.

#### The Medical Profession in Germany.

THE condition of the medical profession in Germany can be gauged by a warning to those thinking of entering the profession recently issued by the German Practitioners' Association. The Central Committee, who are responsible for the form of the warning, describe the condition of the medical profession as "difficult and perhaps unfavourable" and its prospects as sad. They attribute this to three causes, the overcrowding of the profession, the abolition of anti-quackery laws, and recent legislation dealing with workmen's insurance. The number of medical men has doubled since 1876, while the number of unqualified people who practise medicine has enormously increased. According to the Committee members of the criminal class are largely concerned in bogus practice, and not only collect patients by unscrupulous advertisements, but actually get up meetings for the purpose of publicly vilifying medical men. It is somewhat strange that in a country such as Germany whose people are supposed to be clear-headed, logical, and intelligent, swarms of even cultivated persons flock to these quacks. Should the State continue to refuse to intervene to protect the interests of those whom they have licensed, one of two results are bound to follow. Either the number of those who seek to become qualified will greatly diminish, with the result that a smaller body of professional men will be able, owing to the

absence of undue competition, to maintain the status of the profession, or, the numbers entering will be kept up, but the intelligent and well-educated student will cease to join the profession. In the latter case, the status of the medical profession in Germany will become poorer each year, and the general public will be the first to suffer.

#### The Protection of the Holiday Maker.

AUGUST is the great holiday month for the million. Custom and convenience have established this period of the year as the season for life's physical renewal. Judged from the physiological and hygienic standpoint much might be said in favour of a re-arrangement of the year's recreation days. But at least in this matter the wishes of the majority must be respected. Life, it would seem, cannot be controlled in all its bearings by the stern commands of science. But whoever the holiday maker may be, and wherever he may choose to go for his mental rest and bodily renewal, science may well insist that reliable measures should be taken to protect him from the evil results of his own ignorance and folly. At present much disaster accrues to many from the non-hygienic commissions and omissions of the holidays. Even the strictest and most careful of would-be sanitarians at this season of the year oftentimes seems to throw discretion to the winds and plunge into extravagances and excesses unwarranted. But the sowing of recklessness speedily brings a harvest of regrets. The conduct of a holiday calls for much discrimination, wise discernment, and painstaking arrangement. We believe medical men might well exert a greater influence in instructing those to whom they stand in the responsible position of medical advisers as to the management and control of a hygienically-directed holiday. The haphazard method of selecting a resort, taking rooms, travelling thither and then drifting with the tide of a vulgar multitude in the pursuit of so-called enjoyment, cannot be too strongly condemned. Every medical man knows that the annual holiday is a fruitful season for the propagation of many forms of infectious disease, the initiation of not a few serious morbid conditions and the wasteful expenditure of much human energy. An injudiciously-conducted holiday oftentimes requires a second rest and recreation period under medical supervision to rectify ills which might well have been avoided.

#### Sundown Literature.

A PAPER which was recently read before a Medical Editors' Association in America, with the suggestive title of "Sundown Journalism," contains several important truths on the causation of much of the weakness of medical literature at the present day. Sundown work is work done after and in addition to the ordinary labours of the day; it may, in the case of the budding medical

man, be started at a "sundown college" and after he has become qualified may be continued in "sundown literature." "It is the work done when the brain and body are debilitated and below par from the strains and labours of the day." According to the writer, many of the American journals and medical works contain marked examples of sundown literature stimulated by drugs, and characterised by a jarred and exclamatory style from the effects of alcohol, or by the softer notes and the assertive confidence in which conclusions are stated under the influence of morphia. "The cocainist influences on these contributions are more pronounced than that of any other drug, particularly in the endless repetitions and involved explanations, and movement in a dreamy, hazy mass of words." We further learn that one of the popular text-books on the market is notoriously a midnight work, stimulated by opium and cocaine, while another with a large sale has drug writing and drug work on every page. We can quite believe that the evil of which the writer complains is by no means infrequent, but we doubt that it is as universal as he seems to think. In these countries it is certainly the isolated exception. In America, where life is altogether more hurried and more feverish, it is only reasonable to suppose that resort to stimulants of various kinds will be more frequent. The necessary end of such a course is visible from the start, and is one against which it should not be necessary to warn the medical man.

#### A Chicago Oculist's "Cure" for Intemperance.

IN these modern days medical science has developed a marvellous faculty for detecting the remote origin of this, that, or the other sign, symptom, or abnormal mental or bodily condition. One man studies uric acid with rapt attention, until he ends by ascribing every woe that afflicts humanity to the presence of that evil substance in the tissues. Another detects gout in every patient who consults him, and writes a terrified treatise on "Gout in its Protean Aspects." A third finds an explanation for nineteen-twentieths of all disease in disordered nerves and nerve action, including the hereditary taint of inebriety. The most comprehensive and persevering faddist of latter days, however, is the oculist who traces a myriad maladies to errors of refraction. Hath a patient epilepsy, asthma, herpes, migraine, tic, neurasthenia, headaches, baldness, dyspepsia, tremors, with a number of other complaints, ranging from deafness to dementia?—then let him forthwith seek relief and cure in suitable spectacles. The only thing hitherto sacred to the oculist has been drunkenness, but he has now stormed the last fort. A Chicago oculist has lately published his discovery that inebriety is merely a question of sight. The man whose sight is perfect does not get drunk, and *vice versa*. The matter, perhaps fortunately, can be determined absolutely one way or the other by actual experiment. Two sets of

patients, one with normal and the other with abnormal eyeballs, can be supplied with full doses of alcohol, and the results carefully noted. In order to avoid possible complications the experiments should be conducted in wards with carefully secured doors and windows.

UNDER the will of Mr. C. J. Shaw, of Leamington, the Birmingham General Hospital and the Warneford and Leamington General Hospital each receive a legacy of £2,000; and the Midland Home for Incurables, £1,000. The Stroud General Hospital and the Gloucester General Hospital each receive £300, under the will of Mrs. Winterbotham, of Dursley.

#### PERSONAL.

FROM a trustworthy source we learn that Sir William Turner intends shortly to resign the Presidency of the General Medical Council, and that its next meeting will probably be the last under his chairmanship.

IT is announced that Sir Thomas Barlow and Dr. H. D. Waller have been appointed representatives of the University of London at the International Medical Congress to be held at Lisbon in April, 1906.

PROFESSOR KÖNIG is about to vacate the Chair of Surgery in the Berlin University, the succession to which has, we understand, been declined by Baron von Eiselsberg, the Vienna Professor.

THE report that Professor von Leyden intends to resign his Chair in the University of Berlin has been contradicted.

DR. ALBERT S. GRUNBAUM, Lecturer in Experimental Medicine at the Liverpool University, has been appointed Professor of Pathology and Bacteriology in Leeds University (Yorkshire College) in the place of Professor Trevelyan, who is retiring at the end of September.

WE understand that Mr. Mayo Robson was sent for to operate on M. Waldeck-Rousseau, late Prime Minister of France. He had, however, left London on his way to America at the time, and the operation was performed by Dr. Kehr, the German specialist, assisted by Mr. Armour, Mr. Robson's assistant. Unfortunately, the illustrious patient was in too feeble a condition to combat the effects of the operation, to which he shortly succumbed.

DR. WILLIAM GAYTON has been presented by his colleagues with a handsome testimonial on his retirement from the medical superintendency of the North-West London Fever Hospital, after thirty-four years service under the Metropolitan Asylums Board.

THE Duke of Westminster has subscribed £1,000 towards the fund being raised for paying off the building debt in connection with the Alexandra Hospital at Rhyl.

MR. W. A. H. NAYLOR, F.I.C., F.C.S., of London, is the new President of the British Pharmaceutical Conference, which has just held its forty-first annual meeting, under the Presidency of Mr. T. H. W. Idris, J.P., L.C.C.

A CONSULTING-ROOM thief last week paid a professional visit to Sir Stephen Mackenzie, of Cavendish Square, but was quickly run to earth in a mews hard by on bolting from Sir Stephen's house.

PROFESSOR OSLER will preside at a Congress to be

held in the Medical Department of the World's Fair at the St. Louis Exposition on September 20th. There are twelve sections, presided over by distinguished men from various countries.

MADAME ALBANI will give a concert in aid of the Royal Hants County Hospital, on October 7th. The institution is one of the oldest of the kind in existence.

MR. W. J. CURRIE, of Glasgow, presided over the eighteenth annual meeting of the Federation of Local Pharmaceutical Associations, held last week in Sheffield.

### Special Correspondence.

[FROM OUR SPECIAL CORRESPONDENT.]

#### BELFAST.

MEDICAL ATTENDANT ON THE ROYAL IRISH CONSTABULARY.—Dr. Alexander Montgomery has been appointed one of the medical attendants to the police force in Belfast, in place of Dr. H. M. Killen, resigned. As mentioned in this column last week, there was great competition for the appointment, which is said to be worth about £200 per annum. The selection of Dr. Montgomery for the post is a very popular one.

PORTRUSH COTTAGE HOSPITAL.—A two-day bazaar was held in Portrush last week to provide funds for the furnishing and equipment of the new Cottage Hospital, which has been provided mainly by the generosity of one lady. The Provost of Trinity College, Dublin, was in the chair at the opening ceremony, and made an excellent speech on the subject of the necessity which had arisen for small hospitals in country districts, as well as large institutions in the towns. Dr. J. C. Martin also spoke, and pointed out that Dr. Traill was the first medical man to occupy the important post of Provost of Trinity.

THE SMALL-POX EPIDEMIC IN ULSTER.—During the past week four fresh cases of small-pox occurred in Armagh, and were promptly isolated, and all contact cases looked after. One case has occurred in Monaghan, and the local authorities there, too, are anxiously watching suspects. The people are coming in hundreds for revaccination, and for a few days many had to be refused owing to the small supply of lymph. A plentiful supply is now to be had. Only one new case has been discovered in Belfast during the last ten days, and it is hoped that the worst of the outbreak is now past. Eight cases remain under treatment at Purdysburn Hospital.

PROPOSED MEMORIAL TO DR. McKEOWN.—A meeting was held in Belfast last week to consider the question of a memorial to the late Dr. McKeown, and it was decided that such a memorial was desirable, and a small committee was appointed to make arrangements for it. The senior members of the medical profession are mostly on holiday just now, and the meeting was chiefly a lay one. Emphasis was laid on Dr. McKeown's services to the cause of education in Ireland, and specially to his efforts to improve the conditions of the national schools.

#### THE DIMINISHING BIRTH-RATE.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—The diminishing birth-rate is a matter for scientific investigation and full, fair, and orderly discussion. Dr. Taylor has advanced the theory that the fall in question is due to "preventive methods" among married folk, and that these methods are harmful alike to parents and to their non-prevented offspring. My articles in your issues of July 13th and 20th examined the grounds upon which Dr. Taylor based his conclusions. I am no advocate of preventive practices—

Heaven forbid!—but my investigation showed to my own satisfaction that there was not sufficient evidence either that in the United Kingdom the fall was due to preventive practices, or that parents and non-prevented offspring suffered from the practices in question.

Your correspondents, Dr. Drysdale and "A Student of Sociology," go outside the issues raised in the discussion, although their letters are interesting and valuable.

Dr. Taylor implied that it was the duty of married people to produce children indefinitely, regardless of means, of bodily or mental fitness, or of any other factor of environment.

Dr. Taylor on July 27th wrote thanking Dr. Drysdale for dealing with the first part of my paper. Dr. Drysdale supported the view that the fall in the total birth-rate is altogether due to preventive practices. I venture to say that he does not dispose of my argument that the fall is due mainly to other causes. Dr. Taylor, however, classes me with Dr. Drysdale as an advocate of preventive methods, which is unfair and unjust. He then says I fall into a greater fallacy than that which I think I am exposing. The "fallacy" which he seeks to place upon my shoulders in *tu quoque* fashion I fail to comprehend, but gather it has something to do with the suggestion appropriated from my paper that the fall in illegitimacy may be more or less due to the use of preventive methods. In any case, there is no need for him to introduce fresh matter.

Such grounds, Dr. Taylor says, dispose of the "first twelve of my so-called conclusions." I venture to think, however, that a scientific question cannot be dismissed in that cavalier fashion by blinking awkward criticisms and, so to speak, knocking together the heads of one's opponents. Nor are Dr. Taylor's other thrusts and parries more convincing.

I suggested the question of the falling birth-rate in the United Kingdom might well be investigated by a Royal Commission. Dr. Taylor asks if I do not know a Royal Commission has sat on the subject in New South Wales. He might as well refer me to any other Royal Commission of Inquiry on any other subject in any part of the world. Social and economic conditions in New South Wales and in the Mother Country are as chalk to cheese.

Then, again, in your issue of August 10th, Dr. Taylor expresses sorrow for the unnecessary trouble caused to himself and to a "kind correspondent" by Dr. Walsh's mistake in giving 31 as (approximately) the total birth-rate for the *United Kingdom* in 1884. That statement Dr. Taylor and his friend seek to controvert by quoting the total birth-rate for *England and Wales* in 1884, namely, 33'6. It grieves one to see so much sorrow run to waste. It is still more saddening to find inaccuracy of the kind shown by Dr. Taylor and his friend figuring in the columns of a scientific journal.

Truth is truth. The laws that govern the rise and fall of birth-rates will doubtless one day emerge from the mist of futilities in which they are now enshrouded into the full light of knowledge. Meanwhile, irrelevancy and intellectual slovenliness will not mend matters. If Dr. Taylor's views are right they are capable of proof by ordinary recognised methods of formal argument. It is for him to make good his case against all comers.

I am, Sir, yours truly,

DAVID WALSH.

Hanover Street, London, W.

#### SUPERSTITION AND PSYCHOLOGY.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—The letter by Mr. H. Rider Haggard to the *Times* on "Telepathy between a Human Being and a Dog," which you criticised in an able leader on August 3rd, has been followed by another lengthy communication in the same newspaper of August 9th. If the name appended to these letters had not held a place in literature it is hardly possible they would have found admission to the pages of your great contemporary. They may be literature, they are

certainly not science. From the scientific point of view both the letters are equally beneath serious attention. The point of interest, as these letters once more show, is, that there exist vast masses of the people, hardly less numerous among the so-called cultured than among the uneducated classes, who are absolutely ignorant of science and of scientific methods, and as credulous in all questions of natural phenomena as their ancestors who believed in witchcraft, and in the constant occurrence of miracles in the events of daily life. Mr. Rider Haggard apparently sticks to his opinion that the circumstances of his dog's death were communicated to him by telepathy in some form, and seriously discusses the following suggestions to account for the fact:—

- (1) That his own spirit or sub-consciousness travelled to the place and saw the things happen.
- (2) That the telepathic information, considerably delayed in transmission, came from the brain of a human being who witnessed the death of the dog.
- (3) That this is an instance of deferred telepathy, the communication coming from the dog and acting upon his mind hours afterwards in his sleep.
- (4) That his own clairvoyance was the cause.
- (5) That the dog's astral shape visited him.

Mr. Rider Haggard, after critically examining these hypotheses *seriatim*, rejects them all in favour of his previously expressed opinion, that "This curious happening must have been due to some non-bodily but surviving part of the life or of the spirit of the dog." Mr. Rider Haggard declares that his dog Bob was superior to some degraded human beings, and if these beings, as he believes, are "possessed of an immaterial part called a spirit" he does not know why Bob "should not have a spirit also," and why that spirit as it departed hence should not have re-produced in Mr. Haggard's consciousness, "with which in life he was so familiar, the dramatic circumstances of his end, or as much of them as he considered necessary and important"!! Mr. Rider Haggard "does not say that this is so," he can only say he can see no overpowering religious or practical reason to the contrary. Everyone will agree that if an argument is built upon a foundation of pure hypothesis unsupported by a single scientific fact, and mostly revolting to a trained intellect, it matters not what crowning absurdity be accepted to conclude the argument; and if we accept Mr. Haggard's facts and hypotheses we can all admit the possibility of causation of his nightmare to lie in a visitation by the spirit of his faithful dog-friend Bob.

I am, Sir, yours truly,

August 10th, 1904.

H. S.

#### PREVENTION OF PERINEAL RUPTURE.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Like Dr. Duke, I regarded Laphorn Smith's method, referred to in your issue for August 3rd, as ridiculous in the extreme. My object in writing now is to endorse your correspondent's treatment of the perinæum with the object of preventing rupture. I was not aware, until I read Dr. Duke's letter, that anyone had actually suggested a plan of treatment which I have always employed. There must surely be a good deal of intuition in the practice of medicine, for I adopted the method of retracting the perinæum on my own initiative.

I go further, however, than Dr. Duke, for I not only retract the perinæum *during* the uterine contractions, but also *between* the pains. The perinæum being a very elastic structure, it yields readily to traction, and my plan is to pull upon it with either two or three fingers in the vagina. When the perinæum is at all rigid (which is, after all, quite an exceptional occurrence) the administration of a little chloroform greatly aids the carrying out of this procedure, as thereby the parts are made more yielding.

The result obtained by the retraction method is that the head is not forced down on the perinæum during the pains to such an extent as it is when the perinæum is not retracted. The passage of the head is thus

facilitated, and this, I think, is an additional advantage besides that of prevention of perineal rupture.

I am glad to know that my own practice is endorsed by such a valued authority as Dr. Duke.

I am, Sir, yours truly,

JAMES BURNET.

20 Polwarth Crescent, Edinburgh.

August 10th, 1904.

#### METEOROLOGY AND HEALTH RESORTS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—I have before me an article on "Meteorology" (July 3rd, 1889) in THE MEDICAL PRESS AND CIRCULAR. In this present week's number of this journal, August 10th, 1904, there is, on p. 144, a report upon Teignmouth as a health resort; and on p. 159 a notice of Dr. Burney Yeo's book on the "Therapeutics of Mineral Springs and Climates." The most important point to be attended to when dealing with the climate of a place is the nature of the soil. In the article on meteorology we read, "In evidence of this we observe that a committee has been appointed by the Medico-Chirurgical Society, &c.," and in the notice of Dr. Yeo's book we read that the report, "although good in intention, failed to attract the notice which from the reputation of the contributors it deserved." The report did not deserve notice, for it did not follow the principles laid down in the article of July, 1889, and was practically of no value; hence its fate.

It is to be regretted that under the heading "British Health Resorts" there has been shown the same want of scientific and practical knowledge which is absolutely necessary for those who attempt to analyse the value of health resorts. It is to be regretted that this subject is so little understood and is so feebly treated.

I am, Sir, yours truly,

Kensington, August 12th, 1904.

R. L.

#### Obituary.

SIR WILLIAM MITCHELL BANKS, K.C.B., M.D., F.R.C.S.

GREAT regret was occasioned in Liverpool on the receipt of a telegram announcing the sudden death from angina pectoris, of Sir William Mitchell Banks, the distinguished surgeon, who was spending a holiday on the continent. Sir William Mitchell Banks, M.D., F.R.C.S. and a Justice of the Peace for the city of Liverpool, was in his sixty-second year at the time of his death. He was the son of Mr. Peter S. Banks, a well-known Edinburgh solicitor, his mother being the daughter of a Liverpool merchant. The future surgeon was educated in Edinburgh Academy and University. In 1864 he took the degree of M.D. with honours, gaining the University Gold Medal for an anatomical thesis on the Wolffian bodies. He obtained his degree at Edinburgh of LL.D. in 1899. He acted as Demonstrator of Anatomy in the Glasgow University for two or three years, and then settled in Liverpool as an operating surgeon and teacher of anatomy. He soon made his mark, and for many years he has been regarded as one of the foremost surgeons in the Kingdom. In addition to an extensive private practice, he was surgeon to the Liverpool Royal Infirmary, in the establishment of which he spent much time, and gave a great deal of valuable help in a variety of ways. The University College, now the Liverpool University, is another local institution which benefited extensively from his advice and assistance. Other directions in which Sir William found an outlet for his great skill were on the General Medical Council and on the Council of the Royal College of Surgeons of England. One of his most notable works was in connection with the recent development of the Medical School of Liverpool. He took little or no active part in public affairs. His name is especially associated with the advocacy of extensive operative measures for the removal of cancer of the breast and with attempts to discover the most suitable operation for the radical cure of rupture.

SIR FREDERICK BATEMAN, K.C.B., M.D.,  
LL.D., J.P.

It is with sincere regret we announce the death of Sir Frederick Bateman, in the 81st year of his age, on the 10th instant, at his residence, 70 St. Giles' Street, Norwich. Death was due to heart failure, apparently connected with the recent hot weather. Two days before his death he introduced his successor at the Norwich Bethel Hospital, an institution with which he had been connected for more than thirty years. He was the son of a leading Norwich citizen. His first professional post was that of resident surgeon to the Norfolk and Norwich Hospital, to which he was appointed surgeon in 1851, and where he was a student in earlier years. In one capacity and another he was connected with the institution for over sixty years, and he held the position of consulting physician, an appointment conferred upon him at the close of his term of duty as senior physician. Up to the time of his death he was also consulting physician to the Eastern Counties Asylum, at Colchester, an institution in which he took the warmest interest, the Norfolk and Norwich Eye Infirmary, the Jenny Lind Infirmary for Sick Children, the Norwich City Asylum, and the Bethel Hospital—in the case of the latter for thirty years. For a long time he was prominently connected with the public life of his native town. In 1872 he was appointed Sheriff, and in 1892 he received the Queen's Birthday Honour of Knighthood. In 1855 he married Miss Emma Brownfield. He leaves three sons, all living, and all holding honoured positions in the medical profession. Sir Frederick Bateman supported in an eminent degree the traditions that have made Norfolk famous in the annals of medical science.

WILLIAM HOLLOWAY, M.D.LOND., A.M., M.R.C.S.

We regret to announce the death of Dr. William George Holloway, of Hertford Street, Mayfair, an authority on diseases of the throat and nose, at the early age of forty-three years. Educated at Sidney Sussex College, Cambridge, and at St. Mary's Hospital Medical School, he took his B.A., with a first class in the natural science tripos in 1883, and his M.B. with a first class in the second examination in 1886. He was a scholar of St. Mary's Hospital in 1884-85, was admitted a member of the Royal College of Surgeons, England, in 1885, and was prizeman and scholar of St. Mary's in several subjects in 1885-86. In 1890 he proceeded to the M.D. degree. Dr. Holloway had been house surgeon to the St. Leonards and East Sussex Hospital and house physician to the General Lying-in Hospital, Lambeth. He was subsequently for many years connected with the Central London Throat, Nose, and Ear Hospital as clinical assistant, afterwards as pathologist, registrar, and anaesthetist, and finally as senior assistant surgeon. He was a fellow of the British Laryngological and Rhinological Association and a member of the Harveian Society of London and of the British Medical Association.

JOHN RUXTON, M.D.ABERD., OF BLACKPOOL.

DR. RUXTON died suddenly on August 5th at his residence, North Shore, Blackpool. The deceased, who was 56 years of age and married, went to Blackpool about twenty-one years ago. He was one of the consulting surgeons at the Victoria Hospital, Blackpool. Dr. Ruxton lived a somewhat retired life, and took no part in public affairs. His medical education was conducted at Aberdeen, where he graduated M.B., C.M., in 1869, and M.D. in 1883.

JOHN HENRY GREENWAY, R.A.M.C.

THE death is announced of Major John Henry Greenway, of the Royal Army Medical Corps, who died on August 8th, at Wynberg Camp, Cape Town. Major Greenway, who was born in 1857, after completing his education at Guy's Hospital and taking the degrees of L.S.A. and M.R.C.S.Eng., joined the Army Medical Corps in 1885, and attained the rank of Major in 1897. He served in the Orange River Colony during the South African War.

Literature.

ORGANIC NERVOUS DISEASES. (a)

THE need of a thoroughly trustworthy work on diseases of the nervous system, dealing exhaustively and critically with the subject, has long been felt. It is the most difficult and complex portion of the medical curriculum, and its literature is scattered widely over isolated papers in monographs not always easy of access. Dr. Allen Starr is a neurologist of repute, whose contributions have for many years attracted attention, and whose name is as familiar in London as it is in New York. There is no one better fitted, either from familiarity with the history of the subject or from personal experience, to fill the hiatus, and the result of his attempt is a book of 750 pages, profusely illustrated with original engravings and plates in colours and monochrome. A good way of judging of the value of a work on any special subject is to select some particular disease, preferably one of common occurrence, and by careful examination to ascertain how far it comes up to one's ideal. We take as an example locomotor ataxy, tabes dorsalis, or posterior sclerosis. The first thing we notice is, that the author enters into no discussion as to the relative advantages of these terms, and that there is no section devoted to nomenclature. This is but a small omission, and is perhaps hardly worth mentioning. Much more important are the questions of morbid anatomy and pathology, both of which are admirably rendered, all the most recent observations and theories being described in detail. Under the head of etiology there are references to the influence of syphilis in the production or causation of tabes, and the author adduces many arguments against its being of syphilitic (? parasymphilitic) origin, although a predisposing influence in a large number of cases is admitted. It is rare to find tabes in Japan or in China or among the negro races, and yet syphilis is common enough among these people. The symptomatology of tabes is given at considerable length, and we have never before met with an equally comprehensive account of the subject. The less of knee-jerk is, of course, referred to, but is not spoken of as Westphal's sign. The term "iridoplegia" is not mentioned as a synonym of the Argyll-Robertson phenomena. The various crises are well described, including the laryngeal vertigo of Charcot. The author has not seen the gastric crises of the French writers, and does not mention the clitoridectian crisis which accounts for the curious perverted sexual manifestations sometimes met with in erotic women. The Charcot joints are illustrated and an excellent engraving is given of the perforating ulcer of the foot. The author speaks of subluxation with reference to certain joints, but does not employ the term hypotonia. The mental condition is described at some length, the author recognising that there is a close connection between tabes and general paresis. A useful section is devoted to the rarer symptoms of the disease, which might well form the bases of a good examination question. The pages on the treatment of this common and intractable disease are not only thoroughly practical, but are more complete than will be found in any other treatise. We have applied a somewhat severe test, and Dr. Allen Starr has more than answered our expectations.

Turning now to another subject, we find no mention of Morvan's disease in the index, but under the head of "Syringomyelia," there is not only a reference to Morvan's original paper, but a full description, with an excellent and typical series of illustrations showing the trophic change in the hands.

Gilles de la Tourette's disease we do not find mentioned, but it is probably excluded on the ground that it is not due to a gross organic lesion, and is purely functional in character.

The difficult subject of neuritis is dealt with at considerable length. Multiple neuritis first receives

(a) "Organic Nervous Diseases." By M. Allen Starr, M.D., LL.D. Professor of Diseases of the Mind and Nervous System in the College of Physicians and Surgeons of Columbia University, New York. London: Baillière, Tindall and Cox. 1904. Price 25s. net.

consideration, and attention is then devoted to alcoholic neuritis, arsenical neuritis, the multiple neuritis due to poisoning by lead, and other analogous forms. We are glad to find that the neuritis which sometimes follows the administration of sulphonal and trional is alluded to. Under various headings are considered the multiple neuritis of diphtheria, the form accompanying or following attacks of influenza, leprosy neuritis, and the epidemic multiple neuritis known as beri-beri or kakke. All these are described and discussed at considerable length, and much attention is devoted to their treatment.

Other useful chapters deal with such subjects as the diagnosis and location of brain diseases, syphilis of the nervous system, and the muscular dystrophies.

We are greatly pleased with this work, which is probably the best and most comprehensive volume on organic nervous diseases in any language.

#### SURGICAL BANDAGING. (a)

THE author in writing this small work has endeavoured to provide a ready and complete pocket reference book for junior students and nurses in surgical wards.

The book opens with a chapter on the modern treatment of wounds. The older methods of treatment are briefly alluded to and contrasted with those in use at present. The bacteriology of the subject of wound infection is gone into sufficiently to make the treatment of wounds and the reasons for asepsis and antiseptics quite clear. The various antiseptics in use are mentioned and discussed; we would, however, like to see lysol included in the list. Full details of the methods of sterilising dressings and instruments are given. The following occurs on page 21:—"During the process of sterilisation the thermometer should make a heat of 120° F. at least." We did not know before that a thermometer was capable of producing heat, but we would like to see the minimum temperature considerably over 120° F.

The author, in Chapter VI, dealing with the preparation of the patient for operation, says: "The usual steps having been taken to empty the lower bowel." He seems here to forget that he is describing things for the uninitiated.

Several chapters are devoted to bandaging and splints. The various methods and forms are well illustrated and described.

In the chapter on "Nursing in Cases of Injury," much useful information is given for injuries of the different parts of the body.

The book concludes with a chapter on "The Temperature and Pulse," in which the following requires some explanation:—"The pulse should not always be taken on the same side. In some cases the pulse on the right side is slower or more rapid than that on the left side, and there may be other irregularities."

On the whole the book for its size is complete, and one which junior students and nurses will find very handy and useful.

#### LAKE ON DISEASES OF THE EAR. (b)

THIS is an excellent handbook for advanced students and general practitioners, and is published at a very moderate price. Mr. Lake wisely restricts his first chapter to a "brief description of the more important anatomical points," neither plunging into too profuse descriptive details, nor yet scamping the really important ones. The next two chapters are devoted to the general and special examination of the patient, and under the latter heading the author sounds a note of warning as to a cautious prognosis of the curative effect of intra-nasal surgery on aural diseases. During past years intra-nasal surgery appeared to be a panacea

(a) "Practical Guide to Surgical Bandaging and Dressings." By Wm. Johnson Smith, F.R.C.S., Principal Medical Officer, Seamen's Hospital, Greenwich. Pp. 167 and viii, with 70 illustrations. London: The Scientific Press, Limited, Philadelphia: J. P. Lippincott Co.

(b) "Handbook of Diseases of the Ear for the Use of Students and Practitioners." By Richard Lake, F.R.C.S. Eng., Surgeon, Royal Ear Hospital, Lecturer on Practical Otolaryngology, Medical Graduates' College. Pp. x and 32, 54 illustrations and three coloured plates. Crown 8vo. Price 6s. net.

for most human ills, but we are glad to find that the tide is turning and that it is being limited to its own sphere of undoubted usefulness. The "estimation of the acuteness of hearing" and "the use of instruments" are very well done, but the forceps for cleansing the ear (Fig. 21) would be more useful if curved as in the illustration of Grüber's carrier (Fig. 24), so that the hand of the operator holding it may be kept well out of the path of the light from his head mirror. Diseases and malformation of the external ear, diseases of the middle ear, acute, chronic suppurative and non-suppurative, have each chapters in which their various forms are described as fully as the limits of the book allow. Two very good coloured plates are given of chronic non-suppurative and suppurative diseases of the middle ear; and the intra-cranial complications of the latter have a chapter to themselves, as has the influence of diseases of the middle ear on life assurance.

A useful appendix and index are added. The printing, binding, &c., are well done.

### Literary Notes and Gossip.

DR. ARTHUR H. RIDEAL has had reprinted from the *Army and Navy Gazette* of February 13th last, his article on "National Physique and an Ideal Army." The scheme he suggests is that all boys should be compulsorily trained with a view to their military usefulness as Volunteers in the event of national danger. He calculates that in eight years from the initiation of the scheme there would be more than a million well-trained young men at the service of the country in case of need, and that in course of time every able-bodied man in the Kingdom would be sufficiently trained to take up arms at once in defence of the Empire.

\* \*

RECENT mishaps as regards the leaving of instruments in the abdominal cavity have caused much commotion, both inside and outside the medical profession. As it seems clear that the surgeon cannot trust the ordinary methods of checking instruments used at an operation, it will be wise to adopt some system whereby exact written dates can be referred to at a glance. Such a plan is offered in the "*A B C Instrument Check Book*," designed by A. E. S. Waters, M.R.C.S. Eng., and published by Sharman and Co., of March. It has a heading space for name of patient, date, and other details, followed by a list of instruments, with their number, both before and after operation. At the foot is a blank space for the signature of the person responsible for the instruments. The idea is a good one and well carried out.

\* \*

MESSRS. W. B. SAUNDERS AND Co. announce that the new (second) edition of Pusey and Caldwell's work on "Röntgen Rays in Therapeutics and Diagnosis" will be ready in about two weeks, the first edition being exhausted. The new edition will be increased by about 100 pages, and the case histories will be brought down to date. The price of the work will remain as heretofore, 21s. net. The same firm will also publish in the autumn an important new work on the "Vermiform Appendix and its Diseases," by Dr. Howard A. Kelly.

\* \*

It is officially announced that the *London University Gazette* will appear at longer intervals than hitherto. Eleven numbers, instead of twenty, will be published in the course of the Academic year, on Wednesdays, at average intervals of four weeks. The first will be issued on September 28th, 1904; and the dates of the other numbers will probably be,—November 9th, December 7th, December 28th, February 8th, March 8th, April 5th, May 31st, June 21st, July 19th, and August 9th.

\* \*

WE have received three interesting booklets in paper covers from the "Simple Life Series," published by A. C. Fifield, of Fleet Street, London. No. IX is the classical "Walden, My Life in the Woods," by

H. D. Thoreau; No. X. "Tolstoy as a Schoolmaster," by Ernest Crosby; and No. XI "Master and Man," by Leo Tolstoy. The price of each volume is sixpence only, yet the printing, paper, and publishing are of first-rate excellence. Our readers could hardly make a better investment as regards cheap reproductions of good literature. No. XIII of the same series costs threepence. It is the well known essay of Ralph Waldo Emerson upon "Culture."

\* \* \*

THE Orthops Test Chart is a convenient combination for the consulting room. It measures forty inches by twenty-five inches, and contains:—(a) An arc of radiating bars; (b) a series of Snellen's test types; (c) a revolving astigmatic diamond, and (d) a muscle test. The arrangement and size of the bars and the spaces between them on the revolving disc and the radiating arc are such that a small degree of astigmatism can be made manifest, and the principal meridians determined with great exactitude. The figures of the muscle test are printed on one side in red and the other in green. The chart being a combination of various charts, it occupies a minimum of wall space. The chart has been designed by Mr. Lionel Laurance, and is published by Messrs. Storey and Co., of Leeds.

### Laboratory Notes.

#### DIGITALONE.

MEDICAL men frequently complain of irritation following the hypodermic injection of digitalin. Moreover the preparations placed on the market as digitalin vary greatly in composition and in physiological activity, some of the commercial products consisting of digitoxin, or mixtures of digitoxin and digitalin. To overcome these defects and to provide a preparation perfectly suitable for hypodermic use, Parke, Davis and Co. have introduced digitalone, a non-alcoholic, non-irritating, aseptic and permanent solution, representing all the principles of digitalis, of uniform physiological activity, and standardised by physiological assay. The solution is sold in one ounce bottles, equal in strength to one-tenth that of the fluid extract, or four-fifths that of tinct. digitalis B.P., the dose hypodermically being eight to fifteen minims. It supplies a real everyday want of the busy practitioner, to whose notice it may be cordially recommended.

### Medical News.

#### Morphia Poisoning.

A YOUNG medical practitioner, named Dr. Benjamin Gowing, has died at the Belle Hotel, Maidenhead, under singular circumstances. Dr. Gowing had been missing from his home near Swansea for nearly a week, and at the inquest on Saturday it was stated that it was not known what led him to go to Maidenhead, unless it was to see his stepmother, who was on a visit to the district. A brother-in-law said that Dr. Gowing was in pecuniary difficulties, and was paying the purchase money of his practice by instalments. The jury returned a verdict of death through taking an overdose of morphia by misadventure.

#### Small-pox in a Prison.

SMALL-POX has broken out in the county prison at Worcester, and two prisoners affected with the disease have been removed to the isolation hospital.

#### Cholera in St. Petersburg.

THE *Petit Parisien* says that there have been about 150 cases of cholera in St. Petersburg during the last two days, and much alarm exists among the population. The Prefect of Police, General Foulon, has taken severe measures to crush out the epidemic, which, however, is asserted not to be Asiatic cholera but a relatively benign form of the malady.—*Times*.

#### Small-pox at Buxton.

THE *Buxton Chronicle* announces that six cases of small-pox have broken out at Hyde, and one of the patients, an old lady in her 80th year, has died; the other patients are expected to recover. This is one of the most extensive outbreaks that Hyde has experienced for several years, as the town has generally been very free from the scourge. The sanitary authorities have taken steps to confine the outbreak. After immunity for several weeks, a fresh case has been discovered in the Ashton district.

### PASS LISTS.

#### University of London.

THE following candidates have passed the general Intermediate Examination for internal students in the Faculty of Medicine (alphabetically arranged):—Ella Mabel Barker, Charles Anthony Basker, Harold Garfield Bennett, Sylvia Rose M. Blackstone, Mary Alice Blair, Harry Blakeway, Gerald Tyler Burke, Thomas Wm. Higgins Burne, Angel Camacho, Thomas E. Ashdown Carr, Henry Joseph Cates, Herbert Stanley Chate, Bertram Walter Cherrett, Arthur Beauchamp Coomber, Herbert Rees Davies, Kenelm Hutchinson Digby, Reginald Lionel Ernest Downer, Sheldon Francis Dudley, Robert Cecil Turle Evans, Marmaduke Fawkes, Allan Baines Fearnley, Wm. Stephen Fenwick, Janet Marcia Fische, Alexander Fleming, Sidney Frank Fouracre, Ernest William Giesen, Sidney Wilfred Grimwade, Edith Mary Guest, John Hadwen, Eric Henry Rhys Harries, Henry John Henderson, Tom Shadick Higgins, John Ernest Hodson, Hendrik Houwink, Douglas Walter Hume, Mary Sophia Jevons, Elizabeth Herdman Lepper, Clifford Anthony L. Mayer, Marian Mayfield, Minnie Merrifield, Ethel Mary Morgan, Wm. Poole Henley Munden, Frederic Miller Neild, Henry John Nightingale, Humphrey Nockolds, Edgar Lionel Robert Norton, Charles Aubrey Pannett, Walter Patey, Catherine Payne, August Frederick Perl, Arthur John Scott Pinchin, Edward John Price, Mona Dew Roberts, Richard Cadwaladr Roberts, Henry Charles Samuel, William Octavius Sankey, Marie Simpson, Eliza Macdonald Smith, Henry Joste Smith, George French Stebbing, Alfred K. B. R. W. Taylor, Douglas Compton Taylor, Alfred Chas. Foster Turner, James Richard Henry Turton, Winifred Emmeline Watts, Harry Gordon Webb, Leonard Henry Wootton, Carl Ernst Zundel.

The following have passed the Intermediate Examination in Medicine for external students:—

Laurence Ball, Sydney Herbert Booth, Ernest Frederick Finch, Robert Applegarth Hendry, James Ernest Middlemiss, Edward Selby Phipson, Harry Richardson Rawlings, Arthur Toulmin, Arthur Henry Turner and Joseph Wm. James Willcox.

#### Society of Apothecaries of London.—August, 1904.

THE following candidates passed in:—

*Surgery*.—R. H. Cooper (Sec. II), A. W. S. De Vine (Sec. I and II), E. F. W. Hoare (Sec. I and II), A. C. Story (Sec. I and II), and R. H. Terry (Sec. I).

*Medicine*.—G. B. Messenger (Sec. I), C. S. Scott (Sec. II), I. C. Thorburn (Sec. I and II), A. B. S. Todd (Sec. II), and S. H. R. Welch (Sec. I and II).

*Forensic Medicine*.—C. W. S. Boggs, E. F. W. Hoare, J. E. Jones, I. C. Thorburn, and H. M. Waller.

*Midwifery*.—W. G. H. Cable, and W. R. Elliott.

The Diploma of the Society was granted to the following candidates, entitling them to practise Medicine, Surgery, and Midwifery—R. H. Cooper, A. C. Story, A. B. S. Todd, and S. H. R. Welch.

BARON HENRI DE ROTHSCHILD, of Paris, an M.D. of the University of Paris, who has attained celebrity as a physician in that city, and for several years has been a subscriber to THE MEDICAL PRESS AND CIRCULAR, has been promoted to be a Knight of the Legion of Honour.

## Notices to Correspondents, Short Letters, &c.

**CORRESPONDENTS** requiring a reply in this column are particularly requested to make use of a *distinctive signature or initial*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

**ORIGINAL ARTICLES or LETTERS** intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

**CONTRIBUTORS** are kindly requested to send their communications, if resident in England or the Colonies, to the Editor at the London office; if resident in Ireland, to the Dublin office, in order to save time in re-forwarding from office to office. When sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

**REPRINTS.**—Reprints of articles appearing in this journal can be had at a reduced rate providing authors give notice to the publisher or printer before the type has been distributed. This should be done when returning proofs.

**DR. SCHEER (Algiers).**—Your interesting case of "neurasthenia and deep conscious troubles of sensibility accompanying a very slight and old hemiplegia" is marked for early insertion.

**MR. R. STEVENS.**—The population of London officially estimated to the middle of the present year is given as 4,648,950, but this refers only to the inner circle; including the suburbs it reaches 6,907,000. From official sources we also learn that at the same period of computation Glasgow had a population of 798,000, Liverpool 723,000, Manchester 567,000, Dublin 378,000, Belfast 358,000, and Edinburgh 331,000; all are increases on previous censuses, notwithstanding the "diminishing birth-rate."

### NOT YET EARNED.

"This is the bill from your oculist," said the collector to Mr. Grimly on calling for payment.

"Just take it back to him and tell him that I can't read it with those glasses he ordered me."—*N. A. Medical Review.*

**DR. H. S. E.**—(a) Monro's Manual of Medicine is the most practical single volume work on the subject with which we are acquainted. (b) *Whit's Therapeutics.* (c) *Moore's Meteorology.*

**MEDICUS ETONIENSIS.**—The latest improvement in the incubator rearing of premature infants is to supply oxygen more or less continuously. The chances of the survival of one of these fractional vitalities would obviously be multiplied in that way. We read lately that in New York a tea-party had been arranged for all the children, who had been introduced to the world *via* incubator. On this side of the Atlantic such a gathering would be extremely small. The dramatic nature of the method evidently appeals strongly to the instincts of our transatlantic cousins. There is no particular reason why our country practitioners should not mount to name and fame on the top of an incubator—quite the reverse.

### SLEEPING POTION FOR THE KING.

Zimmerman, who was very eminent as a physician, went from Hanover to attend Frederick the Great in his last sickness. One day the king said to him: "You have, I presume, sir, helped many a man into another world?" This was rather a bitter pill for the doctor, but the dose he gave the king in return was a judicious mixture of truth and flattery. "Not so many as your majesty, nor with so much honour to myself."—*Modern Eloquence.*

**C. H. S.**—The subject demands most careful and delicate handling. At the same time it is obviously true that many acts of religious fervour, historical and otherwise, have arisen from a disordered brain. Supernatural visions, prophecies, and a host of irrational objective and subjective phenomena may be traced to insanity. The reign of science is not yet altogether established in this branch of the world's moral and intellectual development.

**PATEROW, L. L. S.**—It is open to you to point out to your patient that he is paying 7s. 6d. a bottle for his patent medicine the actual value of which is about sixpence. The formula of the stuff is readily obtainable.

**E. K. DYNEVOR.**—Women medical students are not allowed to attend the University classes in Edinburgh and Glasgow, as they are at Aberdeen and St. Andrews, nor will the Colleges of Physicians and Surgeons admit women to fellowship. A special committee of lady doctors practising in Scotland has been appointed to promote the reforms desired.

## Vacancies.

**Aberaman, near Aberdare.**—A fully qualified Medical Man to take Charge of a large Colliery District Practice. Salary £400 per annum, with a free house, coal, assistants dispenser, drugs, &c. No private practice allowed. Applicants must be married. Applications to the Secretary, James Phillips, 10 Pleasant View, Godre Aman, Aberdare.

**North Cambridgeshire Hospital, Wisbech.**—Resident Medical Officer (unmarried). Salary £100 per annum, with furnished rooms, attendance, coals, gas, and washing. Form of application to William F. Bray, Secretary.

**St. Bartholomew's Hospital.**—Physician on the Staff. Candidates must be Fellows of the Royal College of Physicians of London. Applications to W. H. Cross, Clerk.

**Bootle, Liverpool, General Hospital.**—Senior Resident. Salary £100 per annum, with board and laundry. Apply by letter to the Secretary, Borough Hospital, Bootle.

**Royal Lancaster Infirmary.**—House Surgeon. Salary £100 per annum, with residence, board, attendance, and washing. Applications to be made only on a form to be obtained from the Hon. Secretary.

**Ebbw Vale Workmen's Medical Fund Committee.**—Senior Surgeon for the district of Victoria, near Ebbw Vale. Salary £500 per annum. Applications to Dr. Keith Campbell, Ebbw Vale, Mon. Cumberland Sanatorium for Consumption, near Threlkeld, Keswick. Resident Medical Superintendent. Salary £150 per annum. Apply Hon. Sec., 2 Brunswick Street, Carlisle.

**County Asylum, Rainhill, near Liverpool.**—Assistant Medical Officer to act as Locum Tenens for a few weeks. Salary £4 4s. per week, with furnished apartments and board. Applications to the Medical Superintendent.

**Birkenhead and Wirral Children's Hospital.**—House Surgeon. Salary £400 per annum, with board, residence, and laundry. Applications to E. H. Tibbey, Hon. Sec., 60 Temple Road, Birkenhead.

**Devon County Asylum.**—Required at once, an Assistant Medical Officer. Salary commencing at £125 per annum, with board and lodgings. Apply to the Medical Superintendent, Asylum, Exminster.

**Open-air Sanatorium for Consumptives, Limpley Stoke, near Bath.**—To be opened November next.—Resident Medical Officer. Salary £200 per annum, with annual increment £20 to £200. Experience in Sanatorial Treatment essential. Applications to "Chairman," N.A.P.O., 84 Park Street, Bristol.

## Appointments.

**BLAIR, JOHN, M.D.R.U.I.** Honorary Assistant Medical Officer to the Royal Albert Edward Infirmary, Wigan.

**BURTON, H. M.D.Durh., M.R.C.S.Eng., L.R.C.P.I., L.S.A.,** Certifying Surgeon under the Factory Act for the Marple District of the county of Chester.

**CLEVELAND, J. W., M.R.C.S., L.R.C.P.Lond.,** House Surgeon to the Royal Berkshire Hospital, Reading.

**FLAHERTY, J. G., L.R.C.P., L.R.C.S.I.,** Certifying Surgeon under the Factory Act for the Tubbercurry District of the county of Sligo.

**GREENE, ARNOLD J., M.R.C.S.Eng., L.R.O.P.,** Assistant Medical Officer to the Royal Albert Edward Infirmary, Wigan.

**KEMP, W., M.B., O.M.Édin.,** Certifying Surgeon under the Factory Act for the Castledorf District of the county of York.

**LEE, E. H.,** House Physician to the Richmond, Whitworth, and Harwicke Hospitals.

**MACCORMAC, HENRY, M.B., Ch.B.Édin.,** Assistant Resident Medical Officer to the Royal National Hospital for Consumption and Diseases of the Chest, Ventnor, I.W.

**MACLIN, T. E., M.D. Glas.,** Certifying Surgeon under the Factory Act for the Whalley District of the county of Lancaster.

**MACLEAN, EWEK J., M.D., M.R.O.P.Lond., F.R.S.Édin.,** Lecturer on Midwifery (under the Midwives Act) to the University College of South Wales and Monmouthshire, Cardiff.

**PERRIN, E. A., M.D.Lond.,** Certifying Surgeon under the Factory Act for the Whitchurch District of the county of Salop.

**POYNTON, F. J., M.D.Lond., F.R.C.P.Lond.,** Sub-Dean of the Faculty of Medicine, University College, London.

**REES, FERDINAND, M.D.Glas.,** Honorary Assistant Medical Officer to the Royal Albert Edward Infirmary, Wigan.

**RUTHERFORD, J. W.,** House Surgeon to the Richmond, Whitworth, and Harwicke Hospitals.

**SHELDON, HUGH, F., M.R.C.S., L.R.C.P.Lond.,** Civil Surgeon to the Military Hospital, Potchefstroom, Transvaal.

## Births.

**BEVAN.**—On August 6th, at Kensington Garden Terrace, W., the wife of Arthur Bevan, M.D.Lond., of a daughter.

**FALCONAR.**—On August 5th, at Tregenna House, Shirehampton, near Bristol, the wife of H. Barclay Falconar, Surgeon, of a daughter.

**HARRISON.**—On August 6th at the Priory, St. Neots, Hunts, the wife of Ernest Henry Harrison, M.B., B.O., B.A.Cantab., of a son.

**WALKER.**—On August 9th, at Willford Lodge, Esher, the wife of Reginald F. Walker, M.R.C.S., L.R.C.P., of a son.

## Marriages.

**BULLER-COOPER.**—On August 10th, at All Saints', Margaret Street, London, W., Chas. Hy. Buller, M.D.Lond., Tottenhall, Wolverhampton, eldest son of C. H. Buller, Ashby-de-la-Zouch, to Margaret Elsie, second daughter of John Cooke, M.B., F.R.C.S., Bexhill-on-Sea.

**COFFEY-QUINN.**—On August 9th, at St. Michael's Church, Kingstown, D. J. Coffey, M.A., M.B., F.R.U.I., son of the late John Coffey, Tralee, to Maud, fifth daughter of the late Captain M. J. J. Quinn, of Aubrey, Shanganagh, co. Dublin.

**EDLESTON-WRENCH.**—On August 11th, at St. Anne's, Baslow, Derbyshire, E. Shatto C. Edleston, M.R.C.S., L.R.C.P., Nantwick, to A. E. M. (Nancy), daughter of E. M. Wrench, F.R.C.S., J.P., of Chatsworth.

**FERRY-BELL.**—On August 13th, at St. Mary Magdalene's, Enfield, Middlesex, Charles Hall Penny, M.D., of Enfield, to Kate, widow of J. J. Bell, of Gairloch, Enfield.

**THOMPSON-EUTHERFORD.**—On August 4th, at Methodist Church, Manorhamilton, J. Henry Thompson, M.B., Ch.D., Chandlers Ford, Hants, to May, eldest daughter of B. A. Eutherford, J.P., L.R.C.P. and S., Earlsfield, Manorhamilton.

## Deaths.

**BEACH.**—On August 6th, at Winchester House, Kingston Hill, Surrey Emily Dora, wife of Dr. Fletcher Beach, in her 46th year.

**RUXTON.**—On August 5th, at 4 Brighton Parade, Blackpool, John Ruxton, M.D.Aberd., Consulting Surgeon to St. Victoria Hospital, Blackpool, aged 56.

No. 8.

## Original Communications.

### SOME POINTS IN THE OPERATIVE TREATMENT OF TUBERCULOUS DISEASE OF THE KNEE-JOINT.

By K. W. MONSARRAT, M.B., C.M., F.R.C.S.E.,  
Surgeon, the David Lewis Northern Hospital, Liverpool.

DURING the last three years of the cases of tuberculous disease of the knee-joint which I have had under observation, I have had occasion to operate on some fourteen. Of these I have been able to follow the subsequent history in eleven, and to estimate the result of the operative procedure. I wish to make these cases the subject of some remarks relative to one or two points in the operative treatment of the condition. The extent and localisation of the disease present in these cases when first seen are shown in Table I.

TABLE I.

No. of Case.	Disease present when first seen.
1	Internal condyle of the femur, internal tuberosity of the tibia, synovial membrane.
2	Internal condyle of the femur.
3	External condyle, outer tuberosity of the tibia, synovial membrane.
4	Synovial membrane, erosion of cartilage covering the femur.
5	Synovial membrane.
6	Synovial membrane.
7	Synovial membrane, fibrous capsule, and ligaments.
8	Outer tuberosity of the tibia, patella, synovial membrane, capsule, and femoral cartilage.
9	Synovial membrane, capsule, and ligaments.
10	Outer part of the lower femoral epiphysis.
11	Synovial membrane.

A summary of the table shows in three cases synovial membrane alone; in two cases synovial membrane, capsule, and ligaments; in one case synovial membrane, with ulceration of the cartilage; in two cases femoral epiphysis alone; in two cases femur, tibia, capsule, and synovial membrane; and in one case tibia, patella, synovial membrane, ulceration of femoral cartilage and capsule. In six cases the disease was primarily synovial, and in five cases it was primarily osseous. This proportion is not representative, according to some surgeons whose experience of the disease has been large. Mr. Rushton Parker, in his article in the "International Text-book of Surgery," says, "practically always the primary focus is in the bones"; Mr. W. Watson Cheyne says the primary centre occurs "probably more frequently in the bone"; Mr. A. E. Barker says, "in the very young the femur is most frequently the

starting-point, next the tibia, then the synovial membrane, lastly the patella; the older the patient the greater the probability of the synovial membrane being first affected." Whatever the actual proportion may be, it is plain that in a large number of cases arthritis is secondary to osteomyelitis. It is in connection with this that I wish to make the first point of my remarks—the great importance of the early recognition of tuberculous foci in the neighbourhood of the lower epiphysis of the femur, and the great value of early surgical interference dealing with it. In Cases 2 and 10 this was the limit of the disease when first seen, and I will briefly relate the history of each.

CASE 2.—The patient, a boy, *æt.* 3, was brought to hospital in February, 1900. In the previous September the mother noticed that the right "knee" was swollen, although the child complained only occasionally of slight pain. When examined the whole of the lower end of the femur was enlarged, particularly that part corresponding to the internal condyle. Pressure over the front of the condyle caused considerable pain. The depressions around the patella and the general outlines of the joint were normal. The diagnosis was tuberculous osteomyelitis in the lower femoral epiphysis. The limb was fixed on a Thomas's knee splint of the ordinary pattern, and the child attended the hospital as an out-patient, but irregularly, until the following November. The condition appeared to improve, for a time at any rate, and his symptoms became quiescent, but before admission in November the disease had insidiously invaded the joint. On November 29th, I performed an arthrectomy and found an irregular cavity in the internal condyle of the femur communicating with the joint, and collateral destruction of the cartilage covering the inner tuberosity of the tibia; the synovial membrane was but little affected. The bone disease was removed with the spoon, and the surface of the cavity was rubbed with liquefied carbolic acid; the synovial membrane was also removed by dissection. Two months later it was necessary again to open the joint; unhealthy granulation tissue was removed from the cavity in the internal condyle, and carbolic acid was again used. The result—fibrous ankylosis—was satisfactory. The child developed tuberculous vertebral disease later, from which he has also recovered.

CASE 10.—The patient, a boy, *æt.* 4, was admitted to hospital on June 4th, 1902. For about a month he had complained of pain in his knee, and the mother had noticed swelling in it for the same period. On admission, the lower extremity

of the right femur was enlarged, particularly the outer condyle; it was tender on handling, and the skin covering it had a glazed appearance. The child was well nourished and had a healthy appearance. I decided to temporise, and fixed the limb in plaster. By the end of three months it was evident that the disease was not quiescent, although the joint remained unaffected. I therefore decided to attack the disease in the epiphysis, and did so on September 20th. Some weeks after primary healing, I removed some unhealthy granulation tissue by reopening the wound. The present condition is satisfactory, and the joint remains sound and unaffected.

This case supplies a suitable commentary on the first. Had I in the first attacked the disease at once when it was confined to the epiphysis, the child might now have a movable instead of an ankylosed joint. I think it is sound surgery to deal with such a focus as soon as the diagnosis is clear, without any temporising or treatment by rest, and for the following two reasons:—(1) It is difficult to estimate in any given case how near to the joint the disease has encroached, and a short delay may just make the difference between escape and involvement of the joint; and (2) the focus is as a rule accessible and can be thoroughly dealt with.

The recognition of this condition of tuberculous epiphysitis is simple: the symptoms being enlargement of the femoral extremity, usually chiefly affecting the inner part, with some swelling of the overlying soft parts; complaint of dull aching pain; tenderness on handling or percussing the epiphysis, and a normal distinctness of the parapatellar depressions. Passive movement of the joint is at the same time either unattended by pain or causes this to only a slight degree. I ask the question whether treatment by rest and general hygienic measures is not attended by unfortunate results in a considerable number of cases similar to the above. The indications for early operative treatment in a tuberculous focus of this situation differ from the indications for such interference when the disease is in the neighbourhood of the upper epiphyseal line, the difference being chiefly due to anatomical considerations. The tuberculous focus in the neck of the femur can in most cases be reached only through the joint, though cases are on record where such a focus has been reached and eradicated through the great trochanter. On the other hand, the focus in the neighbourhood of the lower growing line is accessible without encroaching on the joint, and favourably situated in regard to drainage, though perhaps in most cases the latter will not be called for.

Among hospital patients it is, unfortunately, the exception to meet with these cases before the joint is infected, and Table I illustrates the fact. This, no doubt, is to some extent due to delay on the part of parents in bringing children for treatment, but also, I think, to a too great confidence in the efficacy of treatment by rest, and to the inadequate carrying out of instructions given by medical men.

Anatomically, the most important point in operating on such a case is the outline and limits of the synovial membrane. I have constructed Figs. 1 and 2 from examinations on the cadaver, which show the following points:—(1) That in extension the lateral reflexion leaves uncovered the greater part of the lateral and posterior aspect

of the femoral condyle both externally and internally; and (2) that on flexion, these aspects are almost entirely covered.

In Case 10 I gained access to the focus from the outer posterior aspect; a two-inch incision was made parallel with, and in front of, the biceps tendon downwards as far as the lower extremity of the outer condylar ridge; inwards and downwards from this incision the surface of the bone was reached to the inner side of the outer head of the gastrocnemius. In a similar case I would in future make an incision through the skin over the outer side of the condyle, and having exposed the capsule, strip this and the synovial membrane forwards; I have found on the cadaver that by this means ready access may be obtained to the outer aspect of the condyle without penetrating the synovial membrane. Inasmuch as the tuberculous focus is more commonly situated in the neighbourhood of the inner condyle, a route from the inner side will more often be called for. Mr. W. Watson Cheyne recommends a curved incision, with its convexity upwards at the junction of the condyle with the shaft; this outlines a skin flap which is turned up, and a vertical incision through the muscular fibres towards the back of the condyle exposes the capsule, which is stripped downwards. I have found on the cadaver that simple vertical incision, similar to that which I have described for the outer aspect of the joint, gives quite satisfactory access to the postero-internal aspects of the condyle. After exposing the bone, the outer compact layer may be penetrated by a gouge or a spoon, and the disease focus thoroughly scraped out. The cavity remaining should be treated with some satisfactory antiseptic, such as 1 in 500 biniodide of mercury

FIG. 1.

FIG. 2.

FIG. 1.—Line of reflexion of the synovial membrane in extension.

FIG. 2.—Line of reflexion of the synovial membrane in flexion.

in spirit; hæmorrhage may be checked by tight gauze packing for a few minutes, and the wound may then be entirely closed without drainage.

I wish next to refer to the results of treatment in the ten cases in which the knee-joint was opened: first, as to the recovery from the disease; and secondly, as to the subsequent functional value of the limb. The results as to recovery are shown in Table II.

By recovery I mean present freedom from local disease. In three cases in which recovery ultimately ensued I had to perform erosion twice; in one case (No. 5) the joint went to the bad altogether, owing to septic infection. The

history of this case is as follows. The primary erasion was done on February 14th, 1900, and

TABLE II.

the patient was discharged with the limb in plaster on March 9th, primary healing having taken place. Unfortunately he was not brought again to the hospital until the following May 25th, and when the plaster was removed the wound was found to have reopened, and was obviously infected. In spite of a second erasion it was never afterwards clean, and I performed amputation through the middle of the thigh on April 5th, 1902, with a satisfactory result as far as his general condition is concerned. With regard to the other cases, freedom from disease has been verified by the tuberculin test in Cases 2, 4, and 11; and the others with one exception I have seen within the last few months, and there are no signs of recurrence. The exception is Case 7, which remained under observation for seven months after operation, up to which time no return of the disease had taken place. All that I wish to remark about these results is, that they show that erasion is a satisfactory operation as far as recovery from disease is concerned, even if it be found necessary to repeat it. Such repetition must be due to the overlooking of some of the disease at the first operation. It is hardly necessary to say that asepsis is all-important, and that a knee-joint the subject of mixed infection is practically doomed.

The second aspect of the result is the after-usefulness of the limb for purposes of locomotion. The present state of the limb in these cases is shown in Table III.

TABLE III.

It is almost of the nature of a surgical axiom that what is to be aimed at after erasion or excision of the knee is firm ankylosis of the joint. With regard to excision, this is not only undoubtedly always the desired end, but also in most cases attained without difficulty. With regard to erasion, the question is more complicated. In the first place, after this operation, and in spite of a long subsequent immobilisation of the limb, an ankylosis, that will resist all tendencies to flexion, is not easily obtained; in fact, unless the union is one of bone to bone it must always remain in doubt. With regard to the retention of mobility

Mr. W. H. A. Jacobson says:—"The frequency with which this has been obtained and its advantage have been in my opinion much exaggerated. I have no doubt whatever that a large number of published cases will show that where movement is sought for, the risk is run of a certain degree of permanent flexion, of attacks of pain and swelling, and of the formation of troublesome sinuses. The argument against attempting to retain mobility in the joint is based, therefore, on two grounds: first, *the risk of permanent flexion*; and, second, *the risk of recurrent disease*; and if these two risks can be avoided, it may conceivably be justifiable to endeavour to obtain a functioning joint."

With regard to the question of flexion, I may compare Cases 6 and 9 with Cases 2, 4 and 11. In the one group there was never from beginning to end any tendency to flexion; in the second, flexion occurred and had to be corrected. In the first group I erased the joint by transection of the patella, with reunion of the fragments; in the second, I opened the joint by dividing the ligamentum patellæ. From this comparison and on general grounds I believe that flexion is always likely to occur when the integrity of the extensor is interfered with, and can be largely discounted by leaving this intact. If the extensor is thrown out of action the muscular balance is disturbed, and the hamstrings and the gastrocnemius are given unnatural advantage, the only resistance to flexion being the insecure scar tissue uniting the severed portions of the patellar ligament. Transection of the patella avoids this, provided firm bony union is obtained, and another method which also avoids it is Kocher's—*i.e.*, incision of the capsule on each side of and close to the patella, and division of the patellar attachments of the vasti. Transection of the patella affords ready access to all parts of the joint, and is only open to the objection that it introduces the complication of a transverse fracture, which, if bony union is not primarily obtained, damages the extensor to as great an extent as section of the ligament.

Kocher's method I have performed only on the cadaver. I have found it very difficult to obtain by it satisfactory access to the tibial surface and the posterior synovial recesses. I wish to direct attention to a method of exposing the joint which I think combines the advantages of giving free access to every part and of leaving the extensor entirely intact. A long median incision is made, commencing half an inch below the tubercle of the tibia and reaching upwards to about three inches above the upper border of the patella. (Fig. 3.) This exposes the quadriceps expansion, the patella, and the ligamentum patellæ; the ligamentum patellæ is then split exactly in the middle line, the periosteum of the patella is incised in the same direction, and the extensor aponeurosis is incised to the full extent of the skin incision, the muscular fibres beneath it being separated with the handle of the scalpel. We then have a long incision commencing two inches above the patella, which divides the quadriceps, the periosteum, and the ligament. The patella is then sawn through in the same direction and the joint is thus opened. The upper part of the incision is deepened with scissors so that the whole of the suprapatellar pouch is opened up and the quadriceps is split well above it. Perfect access to

the upper limits of the synovial membrane is thus obtained. When this upper part has been dealt with the lateral pouches are readily cleared, after which the joint must be flexed, and at the same time each half of the bisected extensor, patella, and ligament is retracted laterally until the halves of the patella lie outside the line of the

FIG. 3.—Showing median incision.

femoral condyles (Figs. 4 and 5); the tibial surface and the posterior synovial reflexion are thus exhibited, and dealt with as may be required. When all disease has been removed, the joint is again extended and the halves of the patella fall naturally together and may be fixed with a single wire suture. Continuous sutures above and below the patella bring together the halves of the quadriceps, and the ligament. I think that this procedure fulfils the requirements I have laid down—*i.e.*, free access to the joint and preservation of the extensor.

By preserving the extensor opposition to the hamstrings and gastrocnemius I think that we can discount the first objection to an attempt to retain mobility—the tendency to permanent flexion. The second objection above noted was the risk of recurrent disease. Now, it is, of course, necessary to keep the joint fixed after erosion as long as there is any doubt as to complete recovery from the disease. We are able to judge of this early and accurately by the use of the tuberculin test. I employed this test in Cases 2, 4, and 11 to determine the absence of disease before forcibly straightening the joint; in each no reaction was obtained, and I broke down the adhesions knowing that I was running no risk of setting up recurrence of the disease process. This test might also be used in cases where the retention of mobility was in question, and by its use I think the danger of recurrent disease, the second objection, could

FIG. 4.—Showing patella bisected.

FIG. 5.—Showing the knee-joint flexed and the femoral condyles exposed.

also be discounted. I do not wish to go further than this in discussing the question of attempting to obtain a movable joint after erosion, and, to recapitulate what I have said, such attempts should be confined to cases where the extensor is intact, and where the tuberculin test does not produce reaction, and, in the third place, where the possibility of obtaining a useful joint has not been excluded by removal of the crucial ligaments and joint capsule. Supposing these structures have been severed, and supposing for other reasons that the question of attempting to retain mobility is answered in the negative, how, after erosion, is firm union to be obtained? In a case in which at the operation it is clear that ankylosis is desirable, the joint cartilages should be removed and exposed bone should be brought into apposition with exposed bone, a thin slice off each femoral condyle and the upper tibial surface ensuring that this apposition is sufficient.

Lastly, a word as to indications for operative interference. (1) Cases of tuberculous foci in the neighbourhood of the lower epiphysis of the femur should be operated on as soon as the diagnosis is established. (2) Cases of joint disease by extension from the femur should be operated upon as soon as possible if this extension is recent, and if not recent, then when the disease does not definitely retrograde after about two months' fixation of the joint. (3) Cases of primary synovial disease should be operated on when, after about three months of rest, no distinct improvement has taken place.

*Note.*—Since writing this paper I have heard that the patient in Case 10 has had recurrence of the disease, but to what extent and in what situation I am unable to state.

#### NOTES ON

### THE KLOSOWSKI ANTIMONY POISONING CASE. (a)

By DR. F. J. WALDO.

Coroner for the City of London, and Southwark.

ANTIMONY has been used as the agency for various famous murder cases. Often by medical men—as Pritchard and Palmer—or by persons who have had a semi-medical training. Severino Klosowski, *alias* George Chapman, was a Pole who had passed several years as a hospital attendant. He deserted his wife and afterwards as a publican lived successively with three women, who passed as his wives, and who died one after the other. The last was Maud Marsh, who lived with Chapman (Klosowski) for a year before her death. She became ill, was treated for a time at Guy's Hospital and afterwards at the public-house where she lived with Chapman, under the care of a local surgeon. On October 21st, deceased's mother called her own family attendant from Croydon in consultation. The second medical man, on his way home, suspected poisoning by arsenic, and next day, hearing of the death of Maud Marsh, telegraphed his suspicions to the local medical attendant. The last-mentioned, after receipt of the telegram, held a post-mortem examination on the body of deceased and removed part of the viscera, in which a quantity of antimony was found on chemical analysis. Subsequent re-examination and analysis on my order as Coroner, by Sir Thomas

Stevenson, discovered  $7\frac{1}{2}$  grains of metallic antimony, equivalent to  $20\frac{1}{2}$  grains of tartar emetic in body generally, and particularly in intestines. It was shown that Klosowski frequently administered food and medicine to deceased with his own hands, and that such administration was followed by sickness and diarrhoea. Prisoner was also proved by an entry in the Poisons Book to have purchased an ounce of tartar emetic at Hastings in 1897. Exhumation of the two women who had died previously revealed the remarkable preservation of bodies characteristic of antimony poisoning, though one had been buried five years and the other about eighteen months. In each case Sir Thomas Stevenson recovered large quantities of the metal mentioned. The death of the first victim was wrongly attributed to intestinal obstruction, and that of the second to lung consumption. Chapman obtained £700 from the first of his three victims, but no adequate motive is discoverable in the other two cases.

Points to be noted: Of three deaths, two were unsuspected, the third vaguely at the last moment. Symptoms of antimony poisoning simulate various diseases. Chemists' Poison Register sometimes affords valuable evidence. In all cases of suspected poisoning it is open to medical men to ask advice of the Coroner. Such application should be made invariably by letter and not by word of mouth. Many cases of poisoning generally would be detected were the medical attendant to insist (1) on removal of patient to fresh quarters, and (2) to analyse the excretions and secretions of patient. Common law duty of *all* those about anyone dying under suspicious circumstances to report death at once to Coroner whilst body is fresh and *in situ*, not generally known by the public, and disregarded in present case by the local medical attendant.

Offence not a statutory one and not indictable.

#### Paris Clinical Lectures.

### ABDOMINAL ABSCESSSES AS AN EARLY SYMPTOM OF INTESTINAL CANCER.

By DR. TUFFIER,

Surgeon to the Paris Hospitals.

ALTHOUGH the evolution of intestinal cancer is now well established from the anatomico-pathological point of view, it remains in many respects mysterious and obscure in its clinical aspects. When we get the complete symptomatology, *i.e.*, when we have a patient upwards of fifty years of age who complains of alternating attacks of diarrhoea and constipation, or, it may be, merely of steadily progressive constipation, who gives a history of blood mixed with the motions or of melæna, whose abdomen gradually becomes more and more distended, and, lastly, when, on palpation, we make out the presence of a tumour in the region of the left angle of the colon or the sigmoid flexure, the diagnosis is easy.

But it is exceptional for all these signs and symptoms to present themselves together, and, in particular, all trace of tumour formation may be conspicuously absent. It is common knowledge that one variety of intestinal cancer takes the form of a thick, hard band or ring involving exclusively the intestinal wall, which it gradually contracts, thus reducing the lumen of the canal, though absolutely inaccessible to physical examination. In even more obscure cases the history of the patient's antecedents may reveal neither hæmorrhage nor alternations of constipation and

(a) Abstract of Paper read in State Medicine Section, British Medical Association at Oxford, July 27th, 1904.

diarrhoea. At most there exists some degree of obstinate constipation and it may be that only on closely questioning the patient do we obtain an account of comparatively mild attacks of intestinal obstruction; in short, the condition of things is first revealed by an attack of acute intestinal obstruction. I have seen numbers of these ill-defined cases, and in view of the numerous errors of diagnosis of which I was guilty in my early years, I have come to the conclusion, in patients above fifty years of age, to adopt a conventional limit—all acute intestinal obstruction is the result of intestinal cancer. Though this law may not be strictly accurate, it is clinically trustworthy, and if we apply it to all cases we shall certainly be right in ninety out of a hundred.

To-day I should like to call your attention to a mode of onset less frequently met with, more insidious and consequently less familiar to you. To enable you to judge of its clinical importance, I will relate the history of a patient whom you saw in our wards some months since. The man, æt. 54, was first admitted in May, 1903, for some trouble in the right iliac fossa. Six weeks prior to his admission, while still apparently in perfect health, he noticed some slight pain in the lower right abdomen. He went on working, thinking that it was merely a strain, but in the course of the next few days the pain increased in severity and ultimately obliged him to relinquish work. It was then that he came to see us. I discovered a circumscribed tumour in the iliac fossa reaching down to the pubic arch, and half-way to the false ribs above, extending laterally to within three fingers' breadth of the linea alba. The tumour was fixed on its base, was closely adherent to the iliac aponeurosis, but did not involve the skin, which was normal. Its surface was smooth and regular; it was hard and rather painful on manipulation without obvious fluctuation; in short, we evidently had to deal with a subacute abscess in the iliac fossa. The digestive functions had given no trouble before the first attack of pain, but since that time there had been occasional vomiting after meals. There had never been any hæmatemesis, melæna or marked constipation. The urine was normal, and the patient, a strong, robust man, had only begun to lose flesh within the last few weeks.

Our diagnosis, then, was that of subacute abscess of the iliac fossa, and as such suppurative lesions are almost always of appendicular origin it hardly seemed worth while discussing the probable upshot of the trouble. Nevertheless I had the blood examined, with the following result:—Red corpuscles, 4,154,000; white corpuscles, 10,710; hæmoglobin, 75 per cent. The leucocytes comprised 71 per cent. polynuclear; large and medium mononuclear 19.5 per cent.; lymphocytes, 8 per cent.; eosinophile cells, 1.5 per cent. These figures did not point conclusively to deep suppuration, but it would be a mistake to suppose that the differential diagnosis between suppuration and new growth in the iliac fossa is always easy. In a former lecture (*La Semaine Médicale*, 1901, p. 209), I showed you what valuable assistance hæmatology can be made to yield in doubtful cases where the chronic evolution of the lesion leaves it open to question whether we are dealing with an abscess or with a new growth.

In May, 1903, I opened the abdomen by an incision parallel to and above the pubic arch. The abdominal walls were somewhat œdematous and infiltrated, and deep down in the iliac fossa I came upon an enormous abscess filled with thick, viscid pus. The walls of the abscess cavity were thickened like those of a chronic abscess, but nowhere could I make out any special induration of a kind to raise the suspicion of the existence of a malignant growth. I carefully avoided looking for the appendix and simply provided for free drainage. In the course of several weeks all that remained was a small fistulous tract. The patient's general condition had greatly improved, and he was discharged. I may add that during his stay in the

hospital, and the following five months, he suffered from no digestive disturbance of any kind.

In October, five months after the operation, he came back, and, to my surprise, I found the right side occupied by a smooth, hard tumour, the size of the fist, adherent to the deep tissues. The orifice of the fistula had degenerated into two ulcers with irregular granulating margins resembling epithelioma, and on microscopical examination this diagnosis was confirmed. On introducing a sound through the sinus it passed down to a spongy, friable mass, bleeding readily. The situation of the growth, the good general condition of the patient and the absence of any digestive disturbances induced me to attempt its removal.

On October 14th I carried out the following operation: Having first of all applied the actual cautery to the ulcers to destroy and sterilise the granulations, I shut off the fistulous tract by means of a subcutaneous suture. I then made two elliptical incisions enclosing the ulcerating region; I drew outside the adherent mass as a whole and dissected it from the neighbouring structures. Below, I carefully isolated the tumour, which comprised the cæcum, the omentum, and a loop of small intestine. Adhesions to the femoral artery and vein and to sundry large glands obliged me to dissect off these vessels. I isolated and resected the diseased structures, including the cæcum, to within two fingers' breadth of the ileo-cæcal valve, and on the other side I removed six inches of small intestine. I sealed up the divided intestinal ends of the colon and ileum, and performed lateral anastomosis of the small intestine with the colon just above the blind ends. The subsequent course was uneventful, and the patient was still in good health four months after the last operation.

This is a very good example of the occurrence of what was apparently an ordinary abscess of the iliac fossa, which appeared to be due to subacute appendicitis, but which, in reality, was the first manifestation of cancer of the intestine. Alongside this first case, which, being one of cancer of the cæcum, a somewhat special form of cancer, may not be thought to prove my point, I will now relate two others, the clinical history of which presents a remarkable similarity.

On October 10th, 1901, I was called to see a stout, healthy woman, æt. 67, who had been operated upon two years previously for a unilocular cyst of the ovary. Quite recently her alarm was excited by the gradual development of a tumour in the right lumbar region, as to the nature of which opinions were divided. In two months the tumour had attained the size of a foetal head; it was rounded, smooth, adherent to the abdominal wall behind, and passed upwards beneath the false ribs below the liver, reaching below to the middle of the iliac fossa. Slightly tender on palpation, it was not connected with the liver; it was resonant in front and partially fixed, its movements following those of the posterior abdominal wall. Since the tumour had made its appearance the patient had lost her appetite, and had become somewhat thinner. Her evening temperature was 98.8° F. It had been thought to be an inflamed gall-bladder or a tumour of the liver or the kidney. Personally I inclined to the view that it was a case of subacute perinephritic abscess, though the origin of such an abscess left me in doubt, for I could find nothing in the patient's antecedents to suggest renal, hepatic, or even intestinal infection. The hæmatological examination on October 17th gave 3,900,000 red corpuscles, and 11,470 white, including 89 per cent. polynuclear cells; 3 per cent. large mononuclear; 4 per cent. myelocytes, and 3 per cent. eosinophile cells; a second examination, 3,627,000 red, 19,212 white, with 81 per cent. polynuclear, 10 per cent. small mononuclear, 10 per cent. large mononuclear, and 6 per cent. eosinophile cells. A third and last enumeration gave 3,813,000 red, and 15,941 white corpuscles, with 85 per cent. polynuclear; 2 per cent. small mononuclear, 6.5 per cent. large mononuclear, 5 per cent. myelocytes, and 1.5 eosinophile cells.

These figures were therefore in favour of the diagnosis of a neoplasm, but I adhered to my original diagnosis, and proposed evacuation of the abscess through the lumbar region. This I proceeded to carry out on October 24th, giving exit through the perirenal regions to a large quantity of rather foetid pus. Examination of the walls of the cavity revealed the presence of pronounced induration on the anterior wall, but not greater than one meets with in the walls of certain abscess cavities of slow formation. It was drained, and in a few weeks all that remained was a fistulous tract the size of the thumb, running from above downwards. The discharge, however, remained foetid, though it contained no trace of faecal matter. On introducing the finger one came upon a hard, irregular mass of woody consistence, which bled readily on being touched. I again had the blood examined, and found 3,606,230 red corpuscles and 11,439 white—viz., 85 per cent. polynuclear, 1 per cent. small mononuclear, 3 per cent. large mononuclear, 5 per cent. intermediate, 3 per cent. myelocytes, and 1 per cent. eosinophile cells. The anæmia had therefore persisted and the leucocytosis remained, whereupon we arrived at the conclusion that it was a case of cancer. Before long faecal matter began to come away in the discharge, and a few weeks later large cancerous granulations, recognised as such under the microscope, sprouted from the bottom of the wound, the patient dying four months after with a large malignant growth of the large intestine.

In this case also the first symptom of the existence of an intestinal neoplasm was a pericolic suppuration, the intestinal origin whereof there was nothing to suggest. The blood examination alone threw some doubt on the diagnosis of abscess.

The most noteworthy case of pericolic abscess of cancerous origin is that of a man, æt. 47, who eighteen months ago was in our wards. He was an ex-soldier, who had suffered from dysentery in China, and the disease had persisted as chronic enteritis. He came complaining of a large swelling in the supra-umbilical region, the exact nature of which was very difficult to make out. There was nothing in his history to suggest any intestinal lesion, for his intestinal functions were in the same state as they had been for years past; in short, he had suffered from neither constipation nor hæmorrhage. The swelling in question had been of comparatively rapid formation, and was accompanied by rather severe attacks of pain, the temperature, however, not having shown any marked rise. The tumour occupied the epigastric and umbilical regions, reaching two fingers' breadth below the navel. It was about twice the size of the fist. The skin over it was healthy, but the tumour was adherent to the structures below it, its surface somewhat irregular; it was of putty-like rather than woody consistence, it was dull on percussion, a zone of resonance separating the dull area from the liver.

The patient's antecedents, the persistence of the colitis for upwards of twenty years, the rapidity with which the swelling has developed, the pain and the absence of any pressure symptoms led me to conclude in favour of its being a pericolic abscess situated in the transverse colon, due in all probability to dysenteric ulceration of old standing. The examination of the blood gave 3,990,000 red, and 12,652 white corpuscles, including 73 per cent. polynuclear, 16.3 large and small mononuclear, 10 per cent. lymphocytes, and 7 per cent. eosinophile cells.

On November 7th, 1902, I cut down on the abscess through a median incision four fingers' breadth long, starting from the umbilicus. The omentum was adherent to the abdominal wall, and behind it I cut through some lardaceous tissue which led me into a cavity the size of an orange, filled with grumous pus free from fœtor. The walls of the abscess cavity were thick and indurated. I drained, and a few days later traces of faecal matter appeared in the discharge, a circumstance which excited no surprise, since it was quite possible that an intestinal ulcer had opened into the cavity. He was placed on a dry diet, and the faecal

discharge ceased, his general condition improved, and he appeared to be on the road to recovery. He went on all right for three months, although the fistulous tract persisted, when once more faecal matter began to come away, along with a blood-stained, foetid discharge, and though there was no digestive disturbance the patient began to lose flesh. At the same time we noted the formation of a tumour hard to the touch and irregular in outline, which rapidly increased in size. Unhealthy-looking granulations projected through the wound, the patient became cachectic, and died on February 22nd, 1903.

*Post-mortem.*—Cancer of the transverse colon was found which had involved the omentum, the stomach and the liver.

It was, as you see, a third instance of pericolic abscess that had formed round a neoplasm of the large intestine. The diagnosis presented peculiar difficulty in this case because the long-standing chronic dysentery led one to suspect the source of the trouble to be an intestinal ulcer. In this case also there was complete absence of any digestive disturbances, and the first indication was the formation of a peri-intestinal collection of pus.

It is highly probable that the three cases I have related are by no means exceptional, and that now that I have called attention thereto, many other instances may be brought forward. The mode of progression in these cases is not difficult to imagine. The peri-intestinal suppuration starts in a breaking-down gland consequent upon epithelioma of the intestine, a form of glandular inflammation, due to mixed infection, similar to that often met with in connection with cancer of the tongue, even at a period when the cancerous lesion is of small dimensions. The comparison is the more justifiable since intestinal like buccal ulcers are in contact with a highly infective secretion, so that the intestinal lymphatics may convey not only the cancerous elements, but also the pyogenic germs. The suppuration, moreover, can be explained by the anatomical form of these neoplasms. We are aware, as a matter of fact, that in certain forms of epithelioma there is a tendency to early perforation. If the perforation takes place on a part of the intestinal wall covered by peritoneum, adhesions form, but if on a part uncovered by peritoneum, suppuration is set up in the connective tissue and an abscess results. The first hypothesis agrees with observed facts, for the passage of faecal matter takes place only some days or weeks after the evacuation of the abscess contents. This fact suggests that the perforation of the intestine occurs later.

The exact mode of production of these collections of pus, however, is a matter of secondary interest. The point to which I wish more particularly to call attention is that certain peri-intestinal suppuration of uncertain origin, even in the absence of any digestive disturbance, should raise in our minds the possibility of their being due to the presence of a cancerous lesion of the intestinal mucosa.

## The Seventh International Congress of Otolology.

BORDEAUX, AUGUST 1ST TO AUGUST 4TH.

PRESIDENT, DR. MOURF.

At the opening meeting the President delivered an address upon the history of otology in France, commencing with the work of Duverney in the seventeenth century.

THE CHOICE OF A SIMPLE AND PRACTICAL ACOUOMETRIC FORMULA.

A joint report upon this subject was presented by Politzer, Delsaux, and Gradenigo, who form a permanent committee, meeting once a year, for studying the points still undecided. Quix (Utrecht), Fpanse (Dresden), Trêtrôp (Anvers) and Bonnier (Paris) read papers on the same subject.

## THE DIAGNOSIS AND TREATMENT OF SUPPURATION OF THE LABYRINTH.

Three co-reporters. (1) Brieger (Breslau) said that the radical mastoid operation might lead to the spontaneous cure of a suppuration in the labyrinth; or, on the other hand, the suppuration, latent before, might become active after the operation and provoke a fatal meningitis. Operation on the labyrinth is indicated in acute otitis media, when, with collapse or fever, there is serious disturbance of equilibrium, nystagmus, and rapidly progressive deafness; or when, with labyrinthine symptoms, signs of meningitis appear. In chronic cases there are various indications, which the author gives at length, as well as a description of the modes of procedure. (2) Von Stein (Moscow) distinguishes para-labyrinthitis, peri-labyrinthitis, endo-labyrinthitis, and panta-labyrinthitis, according as the bony capsule, the peri-lymphatic space, the endo-lymphatic space, or all these structures together are affected. (3) Dundas Grant spoke of the relations of labyrinthitis to meningitis and to cerebellar abscess. He dealt with prophylaxis, the early detection of labyrinthine trouble, and the indications for operation. Politzer (Vienna) described the pathological changes in the labyrinth which are produced in serious suppurations of the middle ear, and showed preparations. Panse (Dresden) showed preparations and original drawings of ten cases of labyrinthine suppuration. Escat (Toulouse) reported three cases of necrosis of the cochlea with spontaneous elimination. Two of these occurred in the course of chronic otorrhœa, the third was of special interest. A young man, æt. 21, during an attack of scarlatina, presented the signs of acute labyrinthitis, while the tympanic cavity remained intact. The latter was affected later with a secondary suppuration, and the whole of the necrosed cochlea came away. The necrosis was probably due to septic thrombosis of the cochlear artery. Moure (Bordeaux) showed by means of the cinematograph the characteristic staggering gait of a number of patients with affections of the labyrinth.

## THE TECHNIQUE OF THE OPENING AND THE AFTER-TREATMENT OF OTOGENOUS CEREBRAL ABSCESS.

Three co-reporters. (1) Knapp (New York) showed the encephaloscope, recently devised by Whiting (New York), a useful instrument for examining the walls of the abscess-cavity. He advised cautious irrigation, if the flow of pus is abundant. When the opening gapes there is no need of a drainage-tube. Hernia cerebri is caused by a secondary abscess. Secondary abscesses inside the cranium are not rare, they cause aggravation of all the symptoms and death by encephalitis or meningitis. (2) Schmiegelow (Copenhagen) advises that the operation should be planned so as to make it possible to explore both cerebrum and cerebellum, and should commence by a free opening of the middle ear. The anæsthetic should be given with great caution, owing to the risk of failure of respiration. (3) Botey (Barcelona): The operation should always be commenced by an exploration of the mastoid and tympanum, passing thence to the intra-cranial cavity. He advises that, as a rule, the brain should be punctured through the intact dura before incising the latter, so as to make certain of the existence of an abscess; for, when the dura has been incised by a knife the brain and meninges are much more exposed to infection. He condemns irrigation of the abscess cavity, and advises drainage by means of several small tubes. Gradenigo (Turin) described a special form of intra-cranial complication with the following association of symptoms:—Acute otitis media, severe pain in the corresponding side of the head, especially in the temporo-parietal region, and paralysis or paresis of the external rectus on the same side, without other ocular disturbance. He has himself observed six cases. The symptoms are due to a circumscribed focus of leptomeningitis. MacEwen (Glasgow): Besides treating the aural and cerebral foci, it is necessary to attend to the morbid tract leading from the one to the other. Neglect of this precaution is a frequent cause of recurrences. The instruments for exploring the brain

should be used with great gentleness. If after having incised the dura, no adhesions are found in the sub-arachnoid space, the author leaves a carbolic dressing in place for twenty-four hours, and then incises the brain; by that time adhesions will have formed. As an anæsthetic, chloroform is preferable to ether, which causes œdema of the brain. After the incision, which is made as free as possible, the author irrigates very gently; he uses no drain at all or, at the most, sometimes a strand of gauze.

Among the numerous communications presented were the following:—

Lermoyez and Bellin (Paris): "A Contribution to the Surgical Cure of Acute Otogenous Meningitis."—Two cases of recovery from general meningitis arising from the ear. The first, a girl, æt. 19, with old otorrhœa, after a month of vague general symptoms suddenly developed intense headache, stiffness of the neck, facial paralysis, and Koernig's sign. Lumbar puncture showed lymphocytes, 58 per cent., polynuclear cells, 40 per cent. A large operation upon the petrous bone was performed; the labyrinthine wall was carious, the dura covered with granulations. The following day the temperature fell to normal. Koernig's sign persisted for several days. A week later lumbar puncture showed very abundant lymphocytes, but hardly 1 per cent. of polynuclear cells. Two weeks later the spinal fluid was normal. The local cure was slow on account of a large sequestrum of the labyrinth. Eighteen months after the cure is perfect.

In the second case, a girl, æt. 19, with old otorrhœa, developed Bezold's mastoiditis after a chill. At the operation an eburnated mastoid was found full of thick pus; the dura mater was healthy. Ten days later the signs of meningitis suddenly appeared. Intense headache, stiff neck, vomiting, and fever. Lumbar puncture gave a turbid liquid with intense polynucleosis. The dura was then incised, no pus was found in the meninges, and exploration of the temporal lobe was fruitless. The symptoms of meningitis then disappeared, but there was a relapse a week later. A lumbar puncture was followed by improvement. A second relapse, with inequality of the pupils, occurred after another week. But the cerebro-spinal fluid became normal. From this time the general condition improved, the fever fell gradually, and the headache became intermittent, but the pupils remained unequal for a long time. A sequestrum of the labyrinth delayed the local healing, but eight months later the patient was quite well.

Delie (Yprès): "Tobacco and Audition."—A report of twelve cases with nerve-deafness, tinnitus, and vertigo caused by the abuse of tobacco.

Broeckeaert (Ghent): "Upon Injections of Paraffin while Cold."—The author showed a new and convenient syringe.

Möller (Copenhagen): "The Report of an Autopsy in a Case of Oto-sclerosis."

Molinié (Marseilles): "Two Cases of Occlusion of the Pharyngeal Orifice of the Eustachian Tubes," apparently caused by a rash use of the galvano-cautery.

Cauzard (Paris): "A Case of Caries of both Petrous Bones," in which sequestra came away from the naso-pharynx.

Botey, R. (Barcelona): "The Prevention of Stenosis of the Meatus after Radical Operations on the Ear."—None of the plans hitherto proposed for preventing this complication give a certain result. The author makes an incision through the antero-superior part of the membranous meatus as far as the auricle, passing between the superior edge of the tragus and the root of the helix, where the cartilage is wanting. At the conclusion of the operation a metallic cone, slightly flattened, is introduced and left in place for five or six weeks. The dressing for the deeper parts is introduced through the cone. The results of this plan have been uniformly good; the patients remain with a very large meatus almost concealed by the tragus.

Mignon (Nice): "A Grave Form of Eczema of the Ear," &c.

A museum of pathological specimens, models, and instruments was arranged in one of the rooms at the School of Medicine, where the Congress was held.

A proposal that in future the Congress should be held at intervals of three instead of four years was not carried. The next Congress will, therefore, be held at Buda-Pest in 1908.

During the Congress the President gave a delightful garden-party and banquet to the members at his charming chateau at Carbon Blanc. The delegates were also hospitably entertained by the French Society of Otolaryngology and the French Committee of Organisation, by the Mayor of Bordeaux and by the United Syndicates of the Wine Growers of the Gironde.

CHICHELE NOURSE.

## British Health Resorts.

### VII.—KYNANCE (CORNWALL).

[BY OUR SPECIAL MEDICAL COMMISSIONER.]

THE Lizard district, Cornwall's almost island promontory, has long been known to the adventurous explorer, the enthusiastic naturalist, and the Nature-loving artist, but it can hardly claim conspicuous distinction as a health station. It consists of a tableland elevated a few hundred feet above the sea, very bald and treeless, and without hills to break its uniformity.

The uplands of the peninsula, while offering much of interest to the botanist and tourist, afford but little that is suited to the needs of the invalid. The district is bracing, but the lack of protection from winds, especially those from the east, limits its usefulness as a resort for the health seeker, and, indeed, renders it unsuitable for many cases except during the summer.

"The Lizard may be regarded as a bracing, healthy, and interesting resort for the summer and early autumn, but is not suited for invalids in the winter and early spring." (a)

The coastline of the Lizard is, however, peculiarly fascinating, and many of its sheltered bays and but little-known coves afford protection and furnish climatic conditions well suited to the needs of the feeble. The district at present, it is true, is more adapted to the requirements of the active holiday maker desirous of using wisely a brief period of respite from the stress and strain of daily routine than to the more elaborate and carefully formulated demands of the invalid. The prophylactic value of a judiciously selected holiday resort is now being recognised, and medical practitioners would do well to acquaint themselves with the merits of the Lizard's much indented sea-line, both for themselves and those who may be guided by their advice.

We have visited much of the coast of this district, and can fully endorse the opinion of Mrs. Craik: "For grandeur, for solitariness, and for the sense of immensity which says 'Be still!' to all worldly care, there is no coast like the Cornish coast, and no sea like the Cornish sea." And certainly among the many charming coves of the Lizard, Kynance has first place. The late Lord Leighton, conscious of the psychical influence of the spot, wrote: "Kynance is perfectly unique; it is a lovely picture, and the finest cove in the kingdom."

This is not the place to describe the fascination of colour afforded by sky, sea, sand, rocks, and verdured cliffs. With the ebb and flow of tide an ever varying round of charms is offered to the naturalist and lover of Nature. At low water the wonderful caves in the many hued serpentine furnish endless delights for the explorer. The visitor to Kynance Cove will find no aggressive hydro, vulgar hotel, or commonplace lodging-houses, but a simple, primitive existence and strict hygienically directed life, free from the trammels of fashionable society and the infinite irritations of a popular resort, which may be enjoyed at the unsophisticated little cottage boarding-house kept by the kindly local serpentine worker.

(a) "The Climates and Baths of Great Britain; being the Report of a Committee of the Royal Medical and Chirurgical Society of London." Vol. I. London. 1895.

It is not for us here to describe the many merits of Kynance, but rather to draw attention to its many advantages as an altogether unspoilt natural retreat for the overworked in body and the overwrought in mind. It is far removed from the rush of present-day so-called civilisation and sheltered from much of Nature's inclemency. It is freely exposed to vitalising sunlight and health-bearing sea breezes, and offers excellent opportunities for bathing. The naturalist will find much material and unceasing opportunities for study. We have visited Kynance in the spring and found it an ideal spot, and we learn from those well fitted to express an opinion that even in the winter it is comparatively sheltered, warm, and allows of the conduct of an enjoyable open-air life. The inaccessibility of Kynance is not the least of its advantages, and yet by a little careful arrangement even an invalid may travel thither with a minimum of discomfort.

The Great Western Railway now run fast and in every way convenient trains to Helston, which is 32½ miles from Paddington, in about seven hours. From Helston motor cars and coaches travel to Lizard Church Town, which is only an easy walking distance from Kynance for the vigorous. Delicate visitors should drive by carriage from Helston to Kynance, a distance of about ten miles. Kynance may also be reached by invalids staying at Falmouth by an interesting drive of some twenty miles.

## EGYPT AS A HEALTH RESORT.

UPPER EGYPT (continued from page 16).

[BY OUR SPECIAL TRAVELLING CORRESPONDENT.]

CAIRO might well be described as the Paris of the East. The city is full of avenues, gardens, promenades, cafés, &c. It also possesses some of the most attractive hotels, such as the Ghezireh Palace Hotel (the ancient palace of that luxurious prince, Ismail Pasha), Shepheard's Hotel, and Hôtel Savoy. They are well situated, and adapted with the necessaries for convalescents and those needing the open-air treatment. As a medical man I would specially recommend the Ghezireh Palace Hotel, with its beautiful landscape, situated out of the town, and encircled by lovely gardens. The luxurious comforts of these hotels are, broadly speaking, attainable only by well-to-do people, but for those whose resources are limited, similar accommodation can be obtained at the Pension Tewfik, Pension Margosches, or by inserting a notice in the *Egyptian Gazette*, some time before leaving home, requesting board and lodging with a private family, with terms, &c., in the usual way.

Cairo has some splendid hospitals—the Kasr-el-Aini, having at its head the well-known surgeon of the Levant, Dr. Milton, and to which a medical college is attached. Though the hospital is of considerable size and fitted with the latest modern improvements, it is chiefly for the use of Egyptians, and the nursing being in the hands of the latter, renders it unsuitable for Europeans requiring proper nursing. The smaller English hospital is very neatly kept, with good sanitation and under the guidance of an excellent physician, Dr. Murison. The Deaconess' or Prussian hospital is a pretty little building attended by Dr. Wildt (German) and Dr. Sandwith (English).

About a hundred yards distance from Shepheard's Hotel there exists a bathing establishment, having the latest and most improved requirements of hydro- and electro-therapeutic treatment, with massage, &c., and under the direct supervision of German specialists, who are annually brought out to Egypt by the proprietors during the autumn and winter seasons for the purpose of superintending the establishment; and on the whole it may be said of Cairo, coupled with its climate, temperature during autumn and winter, and the mode of living and the picturesque and kaleidoscopic sight of the different nationalities and Eastern manners, that it constitutes for convalescents and those suffering from chest

diseases, as well as for rheumatic and gouty subjects, a most invigorating and attractive health resort. With regard to sanitation, much has yet to be accomplished. Cairo, in those quarters occupied by Arabs, is filthy and unhealthy, but Cairo, the centre, is clean and healthy. Anyone desiring medical attendance can safely choose among the following well-known physicians and surgeons:—Dr. Milton, Dr. Foster, Dr. Toller, Dr. Murison, Dr. Sandwith, Dr. Wildt, Dr. Coumanos Pasha, and Professor Fornario. Half an hour's distance from Cairo is Helouan, with its well-known mineral spring.

Luxor is about twenty hours' run from Cairo. It contains ancient temples. There are only two hotels—the Hôtel Luxor, which generally has an English physician for the season, and Mr. George Comomilla's hotel. Excepting the antiquities there is nothing attractive here, and nothing worthy of note. The climate in summer is necessarily warm, but in winter it is dry and bracing. Life, however, is very monotonous, and there are no British residents.

ASSOUAN is a healthy little town possessing an attractive hotel (Pagnon's Hotel). There are historical ancient temples, the climate is invigorating, dry, and temperate during the winter, but exceedingly warm during the summer. Medical attendance can be obtained from the English medical officer attached to the Assouan hospital. The climate is indicated as particularly suitable for patients suffering from nervous and constitutional diseases.

WADY HALFA is about six hours' run from Assouan. There are only one or two small hotels worth mentioning. Medical attendance can be had from medical officers attending the military hospitals only by favour. The town is dull and monotonous, but the climate is temperate, healthy, and bracing, and those suffering from hepatic disorders caused by irregular living cannot choose a better place or climate for a season.

[FROM OUR OWN CORRESPONDENT.]

Paris, August 21st, 1904.

### EXPERIMENTAL TREATMENT WITH NUCLEINATE OF SODA.

NUCLEINIC acid, says Prof. Huchard, has been employed by a few physicians for gout as a solvent of uric acid, as a general tonic, and as an anti-tuberculous agent. Seeing that nucleinic acid provoked hyperleucytosis when injected into animals, he charged his house physician to try nucleinate of soda as an anti-infectious agent producing in the organism hyperphagocytosis. M. Huchard employed this in six cases in daily injections of twenty drops of a 5 per cent. solution, representing one grain of the drug. No pain or local inflammation was ever observed during the treatment, proving it to be absolutely innocuous. Of the six cases treated, three experienced no benefit from it, but the success in the remainder was very remarkable. The first of these patients had already been in the ward two months, suffering from pulmonary phthisis. A large vomica was situated in the right apex, emaciation was considerable and progressive, while the temperature rose in the evening to 103°. On July 6th, the patient had arrived at the last stage of the disease—pallor, cyanosis, hæmoptysis, dyspnoea, with all the signs of impending dissolution. As a last resort injection of nucleinate of soda was ordered. The following day, to the astonishment of all, the patient was still alive, and eight days subsequently the patient was able to take strong nourishment—eggs, beef-tea, milk, raw meat. The dyspnoea had entirely disappeared and the patient was able to get up and walk about the ward. The improvement continued each day.

The second case was a man who entered the hospital for pneumonia. This patient, who had had a cough for some time, had got thin, but nevertheless was able to continue his trade as a baker. The day before he entered the hospital he was seized with pain in the side. On examination intense dullness was found over the right apex with crepitant *râles* without wheezing. The temperature was 104°. Pneumonia of the apex of the right lung of perhaps bacillary origin was the diagnosis made. The next day the patient was plunged in stupor, in a half comatose state, answering questions put to him with difficulty. Although the pulse was good (96) the dyspnoea was intense, the face pale and drawn, eyes sunken, the weakness was extreme. An injection of caffein and another of nucleinate of soda were ordered and a stimulating mixture. After the third injection of nucleinate of soda, the symptoms began to rapidly amend, so that on the seventh day the patient was able to get up and take ordinary food.

The third and last case was that of a nurse, *æt.* 20, suffering from typhoid fever of a very grave type; in a delirious, semi-comatose state, with high temperature and profuse and fetid diarrhoea; pulse 120; congestion of both lungs, dyspnoea, intestinal hæmorrhages. After ten daily injections of nucleinate of soda the patient, in spite of her very unfavourable condition, was convalescent. It should be added that the usual treatment—caffein, ergotin and intestinal antiseptics—was continued concurrently with the injections.

Professor Huchard concludes by saying that he intends to continue the experiments with this drug, believing the treatment to be quite rational and in any case it exposed the patients to no danger.

## Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, August 20th, 1904.

At the Society of Charité Physicians, Hr. König spoke on

CHOLECYSTOTOMY AND CHOLECYSTECTOMY, and showed some cases. One of the cases was of interest from the fact that it had been mistaken for a movable kidney, so that nephrorrhaphy was first performed, and afterwards the gall-bladder was opened. Violent pain came on again later, and necessitated another operation, when a stone was found in a diverticulum of the duct; the gall-bladder was now removed. The latter operation should be performed when the calculi were difficult to remove, or a tumour was present, otherwise cholecystotomy would be sufficient.

Hr. Milner spoke on

### CIRCULATORY DISTURBANCES AFTER COMPRESSION OF THE THORAX.

Such disturbances sometimes came on after severe pressure on the thorax. They were accompanied by cyanosis, œdema of the face, and especially of the eyelid, there might be even hæmorrhages into the fundus oculi. There were cases in which the blood was forced backwards out of the thorax along with reflex closure of the glottis.

At the Free Society of Surgeons, Hr. Kroner gave notes of a case of

### INTRA-PERITONEAL TORSION OF THE OMENTUM.

A patient who had a reducible inguinal hernia found one day that he could no longer replace it, and had slight abdominal pain with vomiting. The following day, however, he felt quite well. On the tenth day after this he was admitted into hospital with

irreducible hernia, but with no accompanying symptoms of incarceration. At the operation, dark-looking adherent omentum was found in the sac, although the ring was not tight enough to cause constriction. It was formed into a cord, and an extension of the operation showed that it had the cord-like character as high up as the transverse colon, and that it was several times twisted on itself. The whole omentum was bluish red, with necrotic spots in places. A length of 36 cm. was removed, and the abdomen closed, the patient doing well. The slight character of the symptoms accompanying such serious changes was remarkable. No explanation of the twisting could be made out.

Hr. Sonnenburg had been able to untwist the omentum in a recent case, and saw how it regained its normal colour as this was done. He had also noticed the slight character of the symptoms presented.

Hr. Schroeder showed some

#### FOREIGN BODIES

removed in operation. The first were foreign bodies from the vermiform appendix, among them two oxyurides vermiculares, a splinter of steel, a fragment of walnut shell, a crushed cherry-stone, the two latter in a perityphlitic abscess. Probably they were quite accidental, and had nothing to do with the disease etiologically, except, perhaps, in the case of the piece of steel. Further, a coffee-bean from the trachea, removed from a child by tracheotomy, a plate of teeth removed from the œsophagus, an iron ring a pound in weight, that a man had drawn over his penis six days before, the penis swelling very much afterwards; two Röntgen pictures of projectiles that set up no reaction, and a piece of cartilage from the knee-joint of a girl who some time before had fallen on her knees.

He also showed a man who, after a radical operation on his ear, had complete paralysis of the facial nerve as a consequence. The paralysis had, however, been materially improved by plastic transplantation of a portion of the accessory nerve.

Hr. Rinni spoke on

#### TALMA'S OPERATION FOR CIRRHOSIS OF THE LIVER.

He had performed the operation three times, but two of the patients were in a desperate condition, and died a few days afterwards; in the third case a comparatively favourable result was obtained. The patient was shown. She was admitted into hospital in November last with excessive ascites and brown discoloration of the skin. The liver dulness was small, the spleen very much enlarged. Laparotomy revealed an atrophied liver, a large, hard spleen with a strongly thickened fibrous capsule. Suture of the omentum between the peritoneum and musculature in two large pockets. The ascites quickly reformed, and then began to diminish spontaneously, and had not again returned. The general condition had improved very much, and the discoloration of the skin had disappeared. Probably congenital syphilis was the cause of the illness.

Hr. Borchartd had performed the operation in two cases of syphilitic cirrhosis of the liver, but without any benefit.

Hr. Martens related a case of

#### RENAL SURGERY.

A boy, æt. 13, had suffered from renal colic of the left side with passage of gravel and small calculi. After some time the urine became quite clear, but the pain still persisted. Catheterisation of the ureters showed that the left kidney was much less active than the other. Nephrotomy was performed in November last, when it was found that the left kidney was contracted, but there was no stone. The kidney was

sutured, but the capsule was left open in order to lessen the pressure on the kidney. Since then there had been no more pain.

In a similar case shown some time ago, the pain had ceased as in the one related.

The same speaker also related the case of a married woman, æt. 28, who had fever after separation of the placenta, with vomiting, and a painful resistance on the left side. The urine contained pus corpuscles and blood. Catheterisation of the ureters showed that both kidneys were diseased. As the case went on endocarditis developed, but after some months' illness, the patient eventually recovered.

## Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, August 21st, 1904.

#### OSTEO-ARTHROPATHICA TABES VERTEBRALIS.

RUDINGER exhibited a tabetic patient to the Society for innere Medizin, with kyphosis in the three first lumbar vertebræ, and notwithstanding this morbid condition of the osseous structure, the functional activity of the cord was unimpaired by the lesion. This freedom of movement eliminated several etiological factors in the diagnosis, such as heteroplastic neoplasms in the canal itself. By this observation tumours or aneurysms of the dura mater were excluded, which might be supported by the duration of the disease, which had been under operation for at least four years, and the absence of any myelitic symptom. Then, against tuberculous spondylitis the evidence of no pain, either subjective or objective, and free functional movement in the cord excluded any other diagnosis than osteo-arthritis tabes vertebralis.

The Röntgen rays showed the sacral and lumbar bones in a normal condition with the exception of the second and third lumbar vertebræ. The second was broken on the left side, while the third was broken on the right side, thus making two wedges, bending the column sharply above and below the lesions.

#### GASTRIC ANTHRAX.

Schmidt next showed a few microscopic preparations taken from a patient who subsequently died of the disease. The patient first came under his observation nine days before the exitus. From the clinical observation he appeared to be suffering from a very severe form of general poisoning, as the abdominal symptoms were the most prominent. The epigastrium was tender and swollen, with sickness and vomiting, which led to the first diagnosis of gastritis phlegmonosa, although the possibility of anthrax was taken into account owing to the resemblance of some of the symptoms, and by reason of his trade, a cabinet-maker, which brought him into contact with the hair of animals. There was no diarrhoea or colic with the sickness that lent a strong suspicion to anthrax.

An examination bacteriologically was undertaken to confirm the diagnosis of gastritis phlegmonosa, but nothing could be found in the contents of the stomach to justify anthrax, neither could anything be found in the blood. Shortly after this the patient suddenly collapsed and died.

The post-mortem revealed a large necrotic inflammatory ulcer in the mucous membrane of the stomach, but not a single trace of an ulcer could be found in the bowel lower down. Sections of this ulcer were taken and stained by Gram's method, with the result that anthrax bacilli were found for the first time.

How the infection was carried into the stomach alone is not yet quite clear, although the patient always

blamed the eating of a sausage for bringing on the illness which, strangely enough, commenced the following day.

#### CONSTIPATION AND HYPNOTIC SUGGESTION.

At the Naturforscher, Delius proposed hypnotics for constipation. He commenced by discussing the physiology of alimentation, and said that defæcation did not depend entirely upon the stimulus of the fæcal mass in the bowel, or the innervation of the mucous membrane of the rectum. There is also a central automatic influence to be considered in addition, as the faith of the patient is always a potent factor in the gastric movements, and particularly in defæcation.

When the bowels first become sluggish we know it is due to a loss of innervation of the sympathetic. By the hypnotic suggestion the automatic movements are stimulated, and a stronger innervation wave produced along the whole alimentary tract, which, if repeated, will soon put the bowel in a normal condition. The reverse takes place in functional diarrhœa, and the deeper the hypnosis the more effectual is the remedy. He tells us that out of eighty-four cases treated in this manner, only 4 per cent. failed, 15 per cent. improved, and 79 per cent. were perfectly cured.

Schmidt said that he would rather discourage this treatment altogether. The primary disturbance of constipation is to be sought for in the motor sphere, and by careful attention to feeding all can be accomplished that Delius claims for hypnotic suggestion. For the argument of increased decomposition by bacteria, when long detained in the bowel, is without any force as the bacteria are not increased by constipation.

Naunyn thought the speaker in presenting this subject to the meeting had made a mistake, as the fæces in constipation do not increase in bacteria though long detained in the bowel, which is certainly opposed to the accepted opinion that the longer the fæces are detained in the bowel the greater will be the decomposition.

Schmidt said that he would further emphasise this fact by saying that indol and sulphuric ether are even reduced in constipation, which, he thinks, may be used up intestinal ferments.

Bäumler thought the hypnotic remedy a good one, and likely to be successful.

Fisch thought he had a better agent than hypnotism for constipation in carbonic acid baths when given in proper doses. The latest addition to this subject shows that the dosing must be gradually increased to be effectual. These baths act on the hæmatic circulation as proved by their efficacy in chlorosis, anæmia, debility, and convalescence.

Raether thought the baths may be very good in their way, but the new system was far too expensive for practical use. Each bath, according to the latest tariff, is three marks, while a Sandow only costs one mark and twenty pfennings. He thought the new system was prohibitive.

## The Operating Theatres.

### GREAT NORTHERN HOSPITAL.

**INFLAMED APPENDIX IN THE SAC OF A FEMORAL HERNIA.**—Mr. WARREN LOW operated on a married woman, æt. about 30, who had been admitted for a tender swelling in the right groin. She stated that she had had a swelling there since the birth of her last child, a year ago, but that it had not given rise to any inconvenience. Three days before admission she noticed that the swelling became tender and she vomited. The tenderness and pain in the swelling continued, but the

vomiting ceased. The bowels were opened on the night before admission by means of a laxative. On admission she was not collapsed and did not appear very ill; she had been sick since the onset of the attack, and there was no evidence of intestinal obstruction. In the region of the right femoral ring there was a tender swelling over which the skin was red and œdematous. The patient stated that there had been some attempt made at reduction by taxis. The patient was prepared for operation with the view that the hernia was an irreducible femoral hernia, with an inflamed sac. On exposing the tumour the sac of the femoral hernia was found in the usual position; on carefully incising this some foul-smelling pus escaped, which further examination proved to have arisen from a small abscess outside the apex of the appendix, which was adherent to the sac of the hernia, and in which there was a small perforation. The pus was carefully wiped away and the interior of the hernial sac disinfected before drawing down the cæcum to remove the appendix. This was effected in the usual manner by turning down a cuff of muscle and peritoneum and ligaturing the mucous and submucous coats and afterwards invaginating the stump into the cæcal wall. The sac of the hernia was then tied and removed, the external wound partly closed, a drainage-tube being left in position down to the closed sac. Mr. Warren Low said that the diagnosis in this case was that of an inflamed hernia, a condition sometimes due to injury to the sac or its contents from prolonged taxis. The diagnosis was correct but the cause of inflammation lay in the peculiar contents of the sac of the hernia—namely, the appendix vermiformis, which was undergoing an ordinary attack of appendicitis. He had often met with the appendix in the right inguinal hernia of young children, but he had never yet operated upon a case in which the appendix was in a condition of inflammation, though this complication had been found by other surgeons. It was important, he thought, in such a case to carefully cleanse the sac and the external wound before drawing down the base of the appendix in order to effect its removal as, although no adhesions had shut off the sac from the peritoneal cavity, no general infection of the latter had taken place at the time of operation. Bearing in mind the possible infection of the wound by the foul contents of the sac, no attempt at a radical cure could be made by bringing up a flap of pectineal fascia to Poupart's ligament. For a similar reason a drainage-tube was left in the external part of the wound, though it was considered safe to close the peritoneal cavity. The patient left the hospital about three weeks after operation, never having had an adverse symptom.

### ST. PETER'S HOSPITAL.

**CASE OF NEPHRO-LITHOTOMY.—LARGE CALCULUS.**—Mr. SWINFORD EDWARDS operated on a case of a man, æt. about 40, who came to the hospital complaining of right lumbar pain, with a deposit of pus in the urine, and occasional attacks of hæmaturia. He had undergone operation for stricture some years previously by Mr. Edwards. After the lapse of a few days, Mr. Edwards examined the bladder through the cystoscope under an anæsthetic. The right ureteral orifice was patent and somewhat protruding; pus was seen to be coming down the ureter. On the left side the ureteral orifice appeared normal. The bladder, which was somewhat fasciculated, was otherwise normal and contained no growth or stone. An X-ray photograph was then taken, and

a large shadow or series of shadows appeared in the right lumbar region and seemed to indicate the presence of a large stone or of several stones. Examination of the abdomen showed increased resistance in the right flank, muscular rigidity, and an increase in the area of dulness. The temperature was raised so that a perinephritic abscess in addition to calculous pyelitis was suspected. The patient looked very ill when brought into the operating theatre. He was placed on the left side, and the right flank made prominent by placing a large sandbag under the opposite flank. After section of the abdominal wall, there was a sudden rush of pus from a large perinephritic abscess, the cavity of which Mr. Edwards carefully examined with his finger. He detected the kidney at the bottom of the cavity with a fragment of stone projecting from its surface. The opening through which this came was dilated with the finger; it was soon apparent that a large branched calculus was present. Its removal necessitated an incision through the posterior convex border of the kidney in its entire length. The stone was extracted in two parts with a certain amount of difficulty and with free hæmorrhage, to restrain which the kidney was packed with gauze after the surgeon had made sure that the ureter was patent. Two large rubber drains were inserted into the perinephritic abscess cavity, and the wound closed in the usual way. The patient bore the operation better than could have been expected. Mr. Edwards said it was curious that this patient should not have applied before for relief, as he must have had the stone in the kidney for some years. It was a question, Mr. Edwards remarked, as to whether he had done right in leaving the kidney, for it was problematical how much secreting substance remained. If the wound did not heal up fairly quickly the operator proposed to do a secondary nephrectomy, as he thought this was a better course than sacrificing the kidney at once, for after all it might not be necessary. He thought from the size of the stone that the weight would probably be well over two ounces; its length was four inches, the central part was a kind of waist which had occupied the pelvis of the kidney, and from the upper and lower part of the central portions projected elongated knobs or excrescences, which were evidently casts of the calices; hence could be understood the great difficulty in extracting these portions of the stone which were thoroughly grasped by the kidney substance surrounding each calyx.

A month after operation the patient was progressing in a very satisfactory manner, only a very small sinus remaining.

#### Nuns as Nurses.

MR. SLOANE last week asked the Chief Secretary to the Lord Lieutenant of Ireland whether he was aware that at the meeting of the Newry Board of Guardians three nuns from the Convent in Wexford were appointed as nurses to Newry Workhouse; if he could say where these nurses were trained and what was their qualification; and why these appointments were given to members of a religious order. Mr. Wyndham answered that three nuns who were employed in the workhouse infirmary had recently resigned, and the guardians had elected three other nuns in their places. The latter had had several years' experience as nurses in union infirmaries, including that at Wexford. Protestant patients at Newry were in charge of a Protestant nurse.

Small announcements of Practices, Assistancies, Vacancies, Books, &c.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

### SUBSCRIPTIONS.

Subscriptions may commence at any period of the year. If paid in advance the cost is only 21s. per annum, post free. An edition is printed on thin plate paper for foreign and Colonial subscribers at 21s. per annum, post free, if paid in advance, or 23s. 6d. credit rate.

## The Medical Press and Circular.

“SALUS POPULI SUPREMA LEX.”

WEDNESDAY, AUGUST 24, 1904.

### THE LAST GREAT SACRIFICE FOR HONOUR.

THE annals of civilian life are from time to time illuminated by the record of some heroic act of self-sacrifice. Away from the glamour of military pomp and the stir of battle, some citizen engaged in the pursuits of private life makes the last great sacrifice of his life in response to the call of duty. What greater proof could be given of human faithfulness to high ideals? The bravery of the navy who was killed in saving an express train, and of the driver who stopped his engine deliberately at the cost of his own life, stand blazoned in an undying roll of fame. The recent death of Lady McNeill in an attempt to rescue a little boy visitor from drowning adds another name to the list of honour. The tragedy of that event has suggested to a contemporary—the *Daily News*—the question whether such sacrifice is “worth while.” To put the matter in other words, was it justifiable for a highly-trained member of society to risk her own valuable life for the sake of that of a little child whose value to the community was entirely potential? In a matter of this sort the man of action does not stop to think. He dives into the water without waiting to ask what is the social status of the person he is attempting to save. To the brave man all human life is sacred, and in most cases he is ready to run any reasonable risk in order to save the lives of others. To incur the certainty of death with a remote chance of saving life savours, perhaps, somewhat too strongly of recklessness to constitute bravery of the highest kind. But there is no need to chop moral philosophy over this matter. Happily, the nobler qualities of man survive the sordid struggle for existence into which he is for the most part plunged by the necessities of the case. So long as human nature retains its present characteristics.

so long will men, women, nay, children also be willing to risk their own lives in the attempt to save their fellows. Civilian bravery of this kind often puts in the shade that of the soldier, whose trade it is to deal with life hazards, and to whom every definite risk connotes rewards on an equally definite scale. The miner who heads a rescue party, the railway man who averts disaster from an excursion train, the lad who drags his comrades out of a canal, and the thousand and one civilians who cheerfully risk their lives do it for the sake of mere homespun duty and bravery. To them there looms no peerage or Westminster Abbey in the background. It is only of recent years that a Civilian Order has been created to distinguish civilians who have saved life under circumstances of great bravery. Compare that with the list of honours, titles, orders, commissions, promotions, pensions, decorations and rewards bestowed on the British army in the course of war waged against two small republics in a distant part of the world. The soldier, however devoted and brave, is simply discharging the service which he has contracted to render to the State. The civilian is bound to no one to rescue his fellows from situations of jeopardy by the consideration of reward past, present or future. There can be no greater attribute of man than this readiness to make the last great sacrifice of risking or of sacrificing his life for another. In the medical profession the call arises now and then amid the grey routine of daily work. It is answered, as we all know, in a way that has made us proud of the profession to which we belong. Among strictly professional dangers encountered in that way the most frequent has been the clearing of a choked tracheotomy tube in diphtheria cases by the direct process of sucking the open end. Many a brass tablet in hospitals, and many a stained glass window in infirmary chapels, records the tale of such self-sacrifice, but the heroism of many stands unrecorded to this day. It would be an act of grace were the medical men of to-day to commemorate the names of these heroes who have fallen in the face of one of the most formidable of all infections. In almost all instances, moreover, the life of the highly-trained medical man has been sacrificed in the endeavour to save that of a child or of some individual of less value to the general community. The tradition of such men deserves to be kept green in the memory of their fellows.

#### TEXT-BOOKS ON OBSTETRICS.

A CRITICAL review on some recent American obstetrical text-books appears in the current number of the *Scottish Medical and Surgical Journal* from the pen of Professor Stephenson of Aberdeen. The review taken as a whole may, we fancy, be said to express the opinions of most British obstetricians, though perhaps there are some points in which Professor Stephenson's criticisms are a little over-elaborated. Shortly summarised, he objects to the modern American

obstetrical text-books on the ground of their number, their size, the arrangement of their subject-matter, the unnecessary multiplication of illustrations, the use of micro-photographs, the needless display of the nude, and the encyclopædic character of the books. It is difficult to blame a writer of a book, which purports to be complete, because he says too much, unless he wastes space in mere verbosity, and the latter is unfortunately a charge to which certain of the works alluded to are open. As Professor Stephenson says, "we miss the graphic description, the literary restraint, and the matured opinions of the old masters. The zeal for science is great, so great that it is difficult at times to repress the feeling that much is introduced for rivalry and show." We also miss two other matters to which Professor Stephenson does not allude—the style of the older writers and the use of the King's English "as she is spelt." The illegitimate phrases and words that replace in American books the lawfully derived English originals are pitiable, and are used and adopted not only by native-born Americans, but also by resident Englishmen. We are glad, however, to be able to say that the best of the works which appear on Professor Stephenson's list is singularly free from American peculiarities. We cannot follow Professor Stephenson in his condemnation of micro-photographs. We confess to having formerly held an opinion identical with his—that such illustrations are not successful or instructive, but look learned. It is true that it requires experience to interpret them, but once that experience is gained the photograph becomes instructive in the highest degree—provided that it is a good one. Students of the future will find that it is necessary to learn to read micro-photographs, and having done so, we shall no longer hear that they are not instructive. We can go with Professor Stephenson thus far, that we consider the value of the micro-photograph will be much enhanced by having beside it a key-drawing, which diagrammatically represents the essential points of the photograph. The origin of the American text-book might, we fancy, be found in the dogged persistence with which English works adhere to old theories and old technique. Its present form is the result of the swing of the pendulum slightly too far in the opposite direction, and of the intense desire of certain American writers "to go one better" than their predecessors. It is the tacit approval with which English writers regard repeated vaginal examinations, and their scant allusions to the necessity for aseptic and antiseptic precautions, that has led American writers to write as if condemning all vaginal examinations during labour. On this side of the Atlantic, the danger associated with such examinations has been so persistently under-estimated by the older school, is it any wonder that, with the existing obstetrical mortality, a younger school should tend to the contrary error of over-estimation?

#### ST. JOHN AMBULANCE ASSOCIATION.

A PAPER of great practical interest was read by

Dr. Hamilton, of Newport (Mon.), in the Naval and Military Section of the British Medical Association meeting at Oxford. This paper contained a number of friendly criticisms on the work of the St. John Ambulance Association, and we agree with Dr. Hamilton that this valuable association would be of considerably greater service to the public if some of its methods were subjected to revision. Great credit is due to the association, and to two or three energetic medical men who early allied themselves with it, for having demonstrated first of all the practical utility of such work, and, secondly, the ease with which its application could be acquired by lay persons of no great general education. It is the fashion in many professional quarters to scoff at the enthusiastic first-aiders who arrive panting at the scene of an accident, armed perhaps with a medallion, and offers, on the strength of a few lectures and demonstrations in the use of splints and bandages, to take charge of the patient. No doubt there are cases in which zeal outruns discretion, and we have even heard of instances in which an unobtrusive doctor has found himself supplanted by these ardent amateurs. But we believe these occasions to be rare, and in busy industrial centres and on great railways the practical value of instruction in the immediate treatment of accidents given to servants has been shown over and over again. So long as the first-aiders recognise his limitations, he will do little harm, and he has already undoubtedly averted much suffering, and on some occasions even death itself. When it is remembered that a life of the value of Nelson's was retained for his country's service through the timely application of a scarf by his lieutenant, it behoves one to be chary in joining in the chaff bestowed on those who give up their leisure time to attain skill in the art of acting judiciously in emergencies. On the other hand, Dr. Hamilton is quite right in drawing attention to the low standard of proficiency required by many of the examiners of the St. John Ambulance Association, and to the still more urgent need of continuing the training of the candidates after the first certificate has been gained. The course of instruction mapped out is a good one on the whole, but the number of lectures is quite inadequate for any teacher to convey to persons unacquainted with the elements of anatomy and physiology a tithe of the ideas on which alone correct treatment can be founded. The association naturally wish to secure good returns at the end of the year, so they spread their net widely in the effort to attract candidates for instruction, and it is doubtless satisfactory to them to be able to show a high percentage of passes in their examinations. But it is a matter of grave doubt whether the certification of a large number of imperfectly trained persons as competent to render first aid is not, as it stands, a positive danger to the community. Hundreds of holders of certificates will honestly confess in a couple of years after they have passed the examination that they have forgotten *in toto* all that they

had learned, and even those recently passed make mistakes that would be ludicrous if they were not apt to be attended with serious consequences. In his paper Dr. Hamilton cites a number of instances of misapplied ingenuity that have come within his purview, and most readers will be able to supplement these from their own experience. Now the discredit thrown, and rightly thrown, on instruction that produces these effects is likely to prejudice the whole of this useful movement, and we think the St. John Ambulance Association would do well, while pushing their classes in every legitimate manner, to make their courses longer and more thorough, and their examinations more searching. The number of candidates would probably fall off, but the general utility of the movement would rise. It cannot be gainsaid that the public would be better served by a quarter of the present number of first-aiders if trained to the standard of the teams that take part in the annual competitions. The efficiency of these teams to act in emergencies is as far beyond dispute as is the uselessness of half the lackadaisical young ladies who entertain themselves on winter evenings by listening to the oratorical efforts of perspiring young practitioners who see in ambulance classes a legitimate avenue to local fame. Candidates who are "keen" will take trouble to make themselves efficient; those who are careless need not be encouraged. They will be no loss to anyone. The classes for instruction should certainly be taught for a much longer period than at present, and the question of diagnosis of injuries should be more strongly insisted on. The examiners, taking their cue from the teachers, should make their tests more practical, and should assure themselves not only that the candidate knows how to apply prompt treatment, but that he is likely to recognise the nature of the injury which a patient may be suffering from when he is called upon to help. As things stand, most candidates have never examined an injured person, and when confronted with an accident, stand but a poor chance of diagnosing a fracture from a dislocation, or an epileptic fit from opium-poisoning. Moreover, as Dr. Hamilton insists, it is of vital importance that the holders of certificates should assemble at intervals for practice in their art, lest their little store of knowledge evaporate altogether, and their efforts become a source of danger to their patients. No art can be retained without dint of constant practice. The St. John Ambulance Association have done well in the past; that, however, is no reason why they should not do a great deal better in the future.

### Notes on Current Topics.

#### A New Field for Pharmaceutical Chemists.

It appears that a new field of work is in process of exploitation by chemists, with the direct help of the Pharmaceutical Society. As our readers know, a society known as the Spectacle-Makers' Company has formed itself for the granting of diplomas

to anybody who passes certain examinations, such diplomas testifying that the holder is specially capable of diagnosing various conditions of the eyes, fitting glasses, &c. Chemists have turned longing glances towards the increased profits that might be made by exhibiting the diploma of the Spectacle-Makers' Company and by fitting glasses on the public, but unfortunately they did not feel inclined to pass "in the subjects of mathematics and heat in the special examination for the diploma in general and visual optics" of the Company. Accordingly a new Society was formed—the Society of Chemist-Opticians, and during the first week of its existence it succeeded in obtaining from the Spectacle-Makers' Company the important privilege that qualified chemists may obtain the diploma in general and visual optics "without the necessity of adding to their knowledge on the subjects of mathematics and heat." Further, the new Society has succeeded in interesting the lecturer on Chemistry at Bloomsbury Square and the Council of the Pharmaceutical Society, with the result that special apparatus is to be obtained for the purpose of teaching the coming chemist how to prescribe glasses. Personally, we are believers in the old proverb—*ne sutor ultra crepidam*.

#### Hygienic Aspects of Religion.

ENDLESS discussion occurs over the so-called conflict of science and religion. In the past vigorous combat has been waged by the respective disciples, and it cannot be denied that many would-be scientists have trespassed from the region of the known into the realm of the unseen and discountenanced much that was peculiarly dear to the faithful. But history is full of evidences of the mischief wrought by religious fanatics who, in their ignorance, have used every effort to hamper the progress of science, and particularly to curtail the service of the healing art. Religion, however, in all lands and in every age has played an active part in directing public and personal hygiene. The importance of health matters has always been insisted upon by the Jews, and the health of other peoples has been extensively influenced by the injunctions of their religious code. It is well to recognise religion as an essential factor in the evolution not only of a people but of each individual. We have no wish to cast reflections upon any religious system which is held in reverence, either in this or other lands, but we are strongly of opinion that medical practitioners, whatever may be their individual religious views, have an absolute duty to discountenance an all too prevalent sacerdotalism which not only encourages but insists upon the carrying on of non-hygienic procedures as necessary religious functions. We are most reluctant to say one word which should bruise the sensibilities of even the most sensitive, but it is necessary to remind dogmatic exponents of certain religious beliefs that they are advocating measures which seriously threaten health, and oftentimes are active in the propagation of actual disease. And we hold that what is scientifically wrong is also religiously wrong.

#### The Disease of the "Ego."

THE consciousness of the "ego" may be classed as one of the prominent symptoms of our times. The psychical phenomenon of which this form of self-consciousness is the immediate manifestation is, of its nature, morbid. The healthy, normal individual, whose muscular system predominates over his cerebral functions, experiences no more concern about his *ego* than about his heart or digestion, in fact, in a state of perfect health and equilibrium all the functions pursue the noiseless tenour of their way without attracting attention or criticism. When one becomes aware of the existence of an organ, in other words, when an organ obtrudes itself on our attention, there is *prima facie* reason to suspect disease or, at any rate, disturbance. Similarly, when a man turns his eyes inwards and begins to scrutinise his psychical entity he is probably on the borderline of neurasthenia. It is a sort of mental "globus hystericus," a subjective sensation which has no anatomical basis, a projection on to the field of consciousness of the result of disturbed cerebral circulation. Only the strongest brains can endure this sustained process of introspection without permanent damage and, fortunately, the pastime is one which the average mind finds little inducement to indulge in.

#### Leishman-Donovan Bodies.

No department of things medical has of recent years expanded at such a bewildering rate as that of tropical medicine, and the stay-at-home practitioner finds himself at a loss to keep pace with the new discoveries and theories that come crowding into the medical journals every week. The whole subject of tropical diseases has been revolutionised during the last decade, and the workers in this great field are rewarded for their efforts in a manner that dazzles the patient plodder in the prosaic laboratories at home. It is little over a year since Majors Leishman and Donovan independently discovered the bodies that are now known by their joint names; yet fresh facts with regard to their nature are reported home by almost every mail. These bodies were just obtained by puncture of the spleen of patients suffering from chronic cachexial fevers, though they could not be demonstrated in the circulating blood. Stained by the Romanowsky method, they are found partly free and partly enclosed in the red blood corpuscles, and show at one end a mass of chromatin united often by a thin process to a smaller mass. They contain no pigment, but the larger mass often shows signs of fission. The parasite has been regarded as a *Pyrosoma*, the best example of which is the organism that causes Texas fever, the epidemic hæmoglobinuria of cattle. Another is the parasite found in the tick fever of the Rocky Mountains. The Leishman-Donovan bodies have been widely searched for and have now been demonstrated in a large number of morbid conditions. In Kala-Azar, the wide-spread cachexial fever of Assam, they have been found in the hypertrophied spleen, and in "Delhi sore" the ulcers

themselves have been shown to contain these bodies, as have the spleen, liver, intestine, lymph-glands, and bone-marrow. The sensational announcement of Captain Rogers of his ability to cultivate trypanosomes from the Leishman-Donovan bodies throws a new and unexpected light on their nature, as it would now appear that man is the intermediate host for the asexual cycle of these parasites, the adult form being the trypanosome which attains maturity in the lower animals. It is to be hoped that this interesting subject may soon be thoroughly understood, as in the parasitology of these pathogenic forms lies the key to most of the unhealthiness of tropical countries.

#### Quinquaud's Sign.

A NEW sign of chronic alcoholism has been lately brought to notice from several quarters, and as it appears to be well authenticated medical men may be glad to avail themselves of such information as it affords. The sign was first discovered by Quinquaud, but was not published to the world till seven years after his death. Since then Maridort and Fürbringer have both directed attention to it. The sign is elicited by making the patient place the tips of his fingers, well spread out, perpendicularly against those of the examiner, when, if the patient is of alcoholic habits, the examiner feels a number of slight shocks as if the phalanges of the patient were rapidly pressed against each other and against the palm of the examiner. The sensation experienced by the examiners is said to be similar to that of crepitus such as is felt in arthritis deformans, but it has also certain indescribable peculiarities of its own. This crepitus can be heard by the stethoscope and sounds like friction, though in autopsies on patients who have exhibited it, no undue dryness or roughness of the articular ends of the bones has been found. Nor has it any relationship with alcoholic tremor, for whereas Fürbringer found marked tremor in only 7 per cent. of drinkers, he found Quinquaud's sign present in nearly 92 per cent. The pathology of the condition that produces this creaking is very obscure, and after discussing it, Fürbringer concludes that it must be a neurosis, but this result is arrived at more by excluding organic causes than by any positive evidence of nervous derangement. The sign is not likely to be of much practical value, but it is certainly an interesting clinical phenomenon.

#### Paracentesis in Pericardial Effusions.

THE tolerance which most of the closed cavities of the body exhibit towards an accumulation of fluid, especially when gradual, affords a remarkable illustration of the indifference shown by living tissues to foreign bodies as long as the latter do not possess any markedly irritating properties. The pericardium, which normally contains only just sufficient fluid for lubrication, may, like other serous membranes, hold a large amount of exudation without causing much inconvenience. Pericardial effusions have attained as much as 4,000 c.c. (seven pints), but such an enormous quantity is

phenomenal. When of large size they are as a rule purulent in character. The diagnosis of fluid within the pericardium is often a matter of difficulty, the condition being sometimes mistaken for pleural effusion. The shape of the area of dullness is the most conclusive sign. The question of paracentesis will become more and more urgent as the gravity of the case increases. Small effusions may occasionally be caused to disperse by means of counter-irritation in the form of leeches or blisters applied to the præcordium combined with the administration of diuretic and cathartic drugs, but actual mechanical removal of the fluid is the only possible mode of treatment for a large effusion. When cardiac embarrassment is well marked no time should be lost in inserting a fine trocar and cannula. Dr. W. S. Thayer, (a) of the Johns Hopkins University, has reported two cases of tuberculous pericarditis with effusion in which paracentesis was performed. In one case over 1,250 c.c. of purulent fluid were withdrawn with considerable benefit. The dangers of this procedure are not great in careful hands, the risk of infecting the pleura being inconsiderable, except in very large effusions. Puncture of the heart, an accident to be avoided, is not necessarily attended with serious consequences. The seat of election for insertion of the needle is in the fourth or fifth left intercostal space, close to the sternal border.

#### Fatal Kindness of a Hospital Visitor.

THE recent disclosures at an inquest upon a poor girl who died in a provincial hospital from perforation of a gastric ulcer serve to illustrate the supreme importance of diet as a factor in certain forms of disease. The deceased, a domestic servant, was lying in a ward seriously ill and had been placed on a rigid diet. Through the mistaken kindness of a fellow-servant she drank a bottle of lemonade, a liquid which can hardly be considered an ideal beverage in a case of gastric ulcer, with the result that she died. The circumstances which allowed such a breach of discipline to take place will, probably, never be fully understood, but it is a lamentable fact that cases of a similar nature occur under the most vigilant circumstances every "visiting" day. Patients' friends smuggle apples and buns into hospital wards, in spite of printed warnings and the sharp eyes of the nurses in charge. Popular ignorance respecting the why and wherefore of "low" diet is so widespread that persons who should know a great deal better sometimes protest the most loudly against the "cruel starvation," as they call it, endured by such a course. Life or death may hang absolutely upon the regular administration of a minute quantity of fluid nourishment, and any abrupt departure from this mode of feeding may be fraught with disastrous results, to wit, in cases of enteric fever. A case occurred not long ago in a London hospital where an irate and utterly irrational parent insisted upon removing her son, who was suffering from typhoid, from the ward and giving him a hearty meal, with

(a) Bull. Johns Hopkins University, May, 1904.

the consequences that might be expected. Such fools' kindness is simply criminal, and in the case of the domestic the jury's censure might have been far stronger than it actually was. The lemonade killed the patient, and the foolish woman who broke the rules and gave that lemonade was directly responsible for the ensuing death.

#### The Glass House Residences of Medical Writers.

A CORRESPONDENT who has had the pleasure of submitting to Professor Clifford Allbutt theses for the M.B. and M.D. degrees of the University of Cambridge writes to us as follows: "We Cambridge men are all proud of our Regius Professor of Physic, and have derived not only real profit from his medical writings but infinite pleasure from their literary form. We owe him, too, a debt of gratitude for his efforts to turn out Cambridge medical graduates who possess scholarly as well as scientific attainments—men of letters as well as good doctors. But *humanum est errare*—even in literary composition—and I fancy that Professor Allbutt's sly humour, which lends such a charm to his writings, will appreciate a little *riposte* from one of the thesis-writers whom he so justly hauls over the coals in the pamphlet you describe in your instructive leader of this week. In composition it is difficult at all times to avoid that kind of fault which one recognises as soon as it is pointed out—faults which are specially apt to creep into what I believe the Americans call "sun-down" literature—namely, writing undertaken in addition to the ordinary routine of the day, and executed when the rest of the world is in bed. But what I should like to draw your attention to, sir, is the following sentence from a letter of Professor Allbutt to the Editor of the *British Medical Journal* of May 23th, 1904. Professor Allbutt is writing about the Government Lunacy Bill, and he appeals to his own experiences when Lord Chancellor's visitor in lunacy. The sentence runs—"Let us be thankful that in the obscurity of these English homes I found, or rarely found, any positive evil." The meaning is obvious, but if Professor Allbutt had inserted one of those negatives that his pupils use so freely, his sentence might have been more correct from the literary point of view. Or was the omission of the negative a passive protest against the redundancy in vogue among thesis-writers?"

#### Work of the National Veterinary Association.

THE annual meeting of the National Veterinary Association was held in Dublin during the past week. Dr. Charles Allen, the President, delivered an interesting address, in the course of which he referred to the recent report of the Commission appointed to investigate the whole question of the transmission of tuberculosis. The whole subject constitutes one of the most supreme interest to the veterinary world. The President next referred to the work at present being done by the Cancer Commission. It was a work in

which the veterinary profession could give valuable assistance, and he was glad to know that many specimens of value from their body had reached those who were doing the work of the Commission. He concluded by referring to the present position of the Royal Veterinary College of Ireland, which four years ago had only existed on paper. A paper on "Epizootic Lymphangitis" was then read by Captain Martin, A.V.D., and another by Professor Woolridge, on "Hæmoglobinuria in Bovines."

#### Copper Sulphate: Friend or Foe?

FOR some reason or other the Health authorities seem to have taken particular umbrage against the presence of copper in preserved peas. Why they should pass by in comparative neglect the wholesale adulteration of the daily food of the people to concentrate their attack on a comparatively unimportant article of consumption is somewhat of a mystery. A recent police-court prosecution resulted in the conviction and fine of a grocer for selling peas and French beans adulterated with sulphate of copper to the extent in the beans of 3.402, and in the peas of 4.00 grains to the pound. The Departmental Report of 1899, by a minority report, recommended that in no case should more than half a grain of metallic copper be permissible to the pound of preserved peas. The prosecuting Medical Officer of Health admitted he knew of no case where injury had resulted from coppered peas. He stated that the ordinary dose of sulphate of copper as an astringent was from half to two grains. Anyone, therefore, taking a pound of the particular peas in question would swallow double the medicinal dose. Phyllocyanate of copper was formed when copper was added in small quantities to peas, a substance that in minute quantity paralysed, and ultimately killed dogs. That fact, apart from the mere question of adulteration, suggests that copper should be used with extreme caution as a medicinal agent. Indeed, its therapeutic use is nowadays extremely limited, as of late years other remedial methods and non-toxic astringent drugs have been introduced into practice. Meanwhile it is to be hoped that the sanitary authorities will regard the prosecution of the sellers of coppered peas as merely a step in the right direction.

#### The Medical Inspection of Schools in Ireland.

AN important paper bearing on the above subject was read by Dr. Edward Magennis at the recent Congress of the Royal Institute of Public Health, at Folkestone. The pith of the paper is that the present neglect of the elementary principles of hygiene in the National schools through the country constitutes a very serious danger to the life of both teacher and pupil, and that the best method of remedying this unfortunate state of affairs would be to attach a Sanitary Department to the Board of Education with medical officers to examine and certify every school. We learn that there is a daily average of something like

850,000 children attending the different primary schools through Ireland; and that the school accommodation is only sufficient for 736,000 even when each child is limited to the apparent minimum of ten square feet of floor space. If the figure of the air-circulation through these places was also known, it would be shown that there was an even greater discrepancy between the necessary minimum of fresh air and the actual amount supplied. We have ourselves frequently passed schools crammed with children, and without any apparent means of ventilation, save what was afforded by the chimney and the cracks beneath the windows and door. We have no hesitation in saying that no theatre, music-hall, or other place of amusement would be sanctioned by the sanitary authorities which deprived its audience of space and of air in the manner that is done by the Irish school authorities. Yet no one is obliged to go to a theatre, while children are compelled to spend the best hours of their childhood in the pestilent atmosphere of the National school. Educationalists and politicians wrangle over the particular form of history or geography to be taught, and spend hours discussing whether a language is of living commercial value or of dead respectability; statisticians and sanitarians lament the terrible ravages wrought by tuberculous disease in Ireland, yet the Irish National schools continue to perform their deadly work on one generation after another of "scholars." If Dr. Magennis succeeds in rousing the Board of Education, he will have accomplished a most valuable task.

#### The Railway Lavatory.

At this season of the year everyone is "at home" on the railway. All sorts and conditions of people collect at our stations and travel in our trains. Oftentimes a departure platform is a veritable hospital where disease in manifold variety may be demonstrated. Tuberculous, syphilitic, cancerous, all congregate at the booking office and no one can deny them the privileges of the traveller. Many of the railway companies have done much for the safety and protection and comfort of their passengers, but during the present year in travelling over a considerable portion of the railway system of this country we have been struck by the many glaring sanitary deficiencies and hygienic defects which abound. At the present time, however, we would draw attention only to one which we believe is liable to lead to much physical disaster. Lavatories are essential to the mental comfort and bodily well-being of railway passengers. In large stations excellent conveniences are usually available, but in country districts and wayside stations arrangements are oftentimes most primitive and altogether insanitary. In many stations we have recently visited, the urinals are ill-constructed, badly drained, imperfectly cleaned, and disgusting to the senses. It would be well if medical officers of health paid more attention to the sanitary deficiencies of railway stations in their

districts. Lavatories are now to be found on practically all our long-distance trains, but even in first-class carriages we have constantly found the closets ill-constructed, imperfectly supplied with necessities, oftentimes dirty and frequently of such a form that all excreta is deposited upon the line, it may be in a busy station. At this holiday season of the year there is urgent need that the sanitarian should insist on the carrying out of prophylactic measures, and foremost among them we would place reform of the railway lavatories.

#### Medical and Dental Companies.

THE extent to which the evil of permitting the registration of companies for the practice of medicine and dentistry has gone is shown by a list of such companies published by our contemporary, the *Chemist and Druggist*. In England alone, there are sixty-two companies registered for the practice of dentistry. In Ireland, there are twenty-two; and in Scotland three. In England, there are fifteen companies similarly registered for the practice of medicine, but in Ireland and in Scotland there are none. The recent decision of the Chief Baron of Ireland has had the effect of checking the registration of such companies, and steps are being taken to deal with those already registered. It is obviously impossible that half a dozen men acting in a corporate capacity can be allowed to perform acts that would be illegal for any of them acting in an individual capacity, and to set at naught the Medical and Dental Acts. The Irish Dental Association deserves the entire credit of having been the means of bringing about a stoppage in the registration of these companies, and we trust that it will continue its efforts until those already registered have been compelled to discontinue their operations.

#### Abdominal Venosity, "Good Capon Lined."

ABDOMINAL venosity is a convenient euphemism for the condition induced in the viscera by a too great laxity of the abdominal walls, and it enables the medical attendant to discuss the evils of a state brought on by high living and sedentary existence without offending the susceptibilities of his patient. The man who would not care to have his "little Mary" described as a "pot-belly" rejoices in being able to tell his friends that his sufferings are due to abdominal venosity. In fact, the term is as great a God-send to the family practitioner's vocabulary as the suggestion of "adipose deposit" for "superfluous fat." To the home and Continental spas abdominal venosity has brought many a shekel, for the plethoric man feels it a duty to his conscience to make some sort of effort to appease outraged Nature—that is, if the effort does not incommode him unduly. A well-known physician has lately suggested a plan which, if faithfully carried out, should render recourse to a spa unnecessary, as every sufferer has the apparatus required for the treatment ready to hand. The object aimed at is to strengthen the muscles of the abdominal wall in order that more

support may be given to the enclosed viscera. There is no exercise so well adapted to this end as rowing, but every city man cannot repair regularly to the river and disport himself in an "eight" or a skiff. A stay-at-home method has therefore been devised. The patient has to divest himself of all superfluous clothing, open his window, and pull out the bottom drawer of his chest of drawers. He then lies at full length on the floor, his feet tucked under the pulled out drawer and his arms extended over his head. The victim proceeds to raise himself into a sitting posture by means of his abdominal muscles, taking care not to advance his arms in front of the line of the trunk. Having gained the sedentary position he lets himself down again, and repeats the performance till the calls of bath and breakfast make themselves heard. Next day he returns to his diversion, and thus he continues till his waist assumes enviable proportions. We have no doubt that the exercise is a splendid one for the purpose, but we should think that no man would appear less of a hero to his own valet than a City Alderman in light attire wrestling with a chest of drawers before breakfast. If he could be induced to do so, the benefit likely to accrue would doubtless be great.

#### **An Irregular Method of Dispensing.**

A CURIOUS case was heard recently before the City Magistrates at Birmingham. A man called Heath, a chemist and druggist, was asked by a messenger from the Health Department to make up a prescription containing twenty-four doses of a quinine mixture, each dose of which was to contain ten grains of quinine and ten minims of dilute sulphuric acid. The defendant made up the mixture and charged two shillings for it. On analysis, it was found that the bottle contained altogether only twenty-three grains of quinine and 141 minims of dilute sulphuric acid. The defendant stated that he would not think of putting half an ounce of quinine into a six-ounce mixture, that if he had done so he would have charged five shillings for the bottle, that he thought a mistake had been made in writing drachms instead of grains and that the prescription was so well written that he did not think a medical man had written it. The magistrates considered that up to a certain point the defendant had exercised a proper discretion, but that he should have obtained the name of the writer of the prescription and communicated with him. They considered that he was negligent and imposed a penalty of forty shillings. The decision appears to us to be warranted by the facts of the case. Ten grains of quinine is a large dose, but how many Anglo-Indians and men who have lived for long in malarial climates would think nothing of twice as much? The price of the twenty-three grains placed in the mixture was about a penny, while that of the 240 grains which were ordered would have been about ninepence: where, then, did the difference of, three shillings in the price of the mixture come in? The point regarding the hand-writing is absurd, and, if it suggested the need for caution, such caution

could have readily been exercised in the manner suggested by the magistrates.

#### **Multiple Tests for Drunkenness.**

OF a truth there is nothing sacred to the hand of science. All the deeply-rooted beliefs of mankind are being ruthlessly torn up and cast into the oven. Take the test of a drunken man. Our forefathers did well enough by asking him to say "truly rural," and to walk a line chalked along the floor. But the medical man to-day will have no parley with rough and ready methods of that kind, fitted only for the ruder efforts of a pre-scientific age. Nowadays, even the ambulance student knows—in theory, at any rate—how to tell the unconsciousness due to alcohol from that of brain mischief. As to the police surgeon, his tests have become simply multitudinous, if we may judge from the report made last week by a London gentleman upon the soberness of a warehouseman charged with singing and dancing on the public footway while drunk. The surgeon confirmed the police charge, and stated he found fifteen symptoms of inebriety. From a scientific point of view it would be of interest to learn how many of those symptoms were due absolutely to alcohol, and how many were capable of a different interpretation. Science is a good thing in its way, medical science, perhaps, especially so, but with multiple symptoms at command the question naturally arises, how is it that persons are so often allowed to die in police cells under the impression they are drunk? The proof of the pudding is in the eating. We doubt if a trustworthy system of detecting drunkenness in police cells has yet been devised.

#### **The Scottish Diplomates' Association and the Title of "Doctor."**

ONE of the avowed objects of the newly-formed Association of Scottish Diplomates is to secure for its members legal recognition of their right to the title of "Doctor." This desire, in the eyes of the *Hospital*, is no less foolish than unjustifiable, and an intimation to that effect has been recently published in the columns of that journal. It is, of course, well recognised by all who are really within the medical circle and are thus acquainted with the trend of professional thought that a considerable injustice is inflicted upon medical diplomates by restricting the title of "Doctor" to the holders of University degrees. The acquired modern sense of the word, to the man in the street, is that of a practitioner of medicine, and it matters not to the average citizen one jot whether his medical attendant was educated within the walls of a university or of a less assuming medical school. The underlying moral of the whole thing is that there should be one portal of admission to the practice of medicine, and one distinguishing title for all who have passed that portal. The feeling of the Scotch diplomates on this point is perfectly natural and laudable, and they will do well to educate the British public somewhat as to the precise value

and meaning of the present multitudinous medical qualifications. In its desire to pour cold water on the policy of the Scottish Diplomates' Association the *Hospital* appears to overlook the fact that the title of its members forms a small detail in a wide and comprehensive programme.

#### PERSONAL

HIS MAJESTY THE KING has been pleased to approve the appointment of Dr. William Osler, D.Sc., F.R.S., to be Regius Professor of Medicine at Oxford, in succession to Sir John Burdon Sanderson, Bart. In 1889 Dr. Osler was appointed Professor of the Principles and Practice of Medicine in the University of Pennsylvania and Physician to the Johns Hopkins Hospital, Baltimore.

MR. C. MOLESWORTH TUKE, M.R.C.S., has been elected President of the West London Medico-Chirurgical Society for the ensuing session, 1904-5.

DR. BERTRAM ABRAHAMS has been appointed Examiner in Physiology to the Conjoint Board of the Royal Colleges of Physicians and Surgeons of England.

THE War Office authorities are desirous of communicating with three ladies, Miss M. C. Bakkes, Mrs. Rutherford, and Miss M. B. Horswell, with reference to the services performed by them as nurses in the Boer refugee camps in South Africa during the period 1901-1903. Any information as to the present addresses of these ladies should be addressed to the Secretary, War Office, Pall Mall, London, S.W.

THE Commission for the Investigation of Pneumonia in New York will consist of the following well-known physicians: Dr. William Osler and Dr. William H. Welch, of Johns Hopkins University; Dr. Edward C. Janeway, of New York University; Dr. J. Mitchell Prudden and Dr. L. Emmett Holt, of the New York College of Physicians and Surgeons; Dr. Frank Billings, of the Rush Medical College of Chicago; Dr. John H. Musser, of the University of Pennsylvania; and Dr. Theobald Smith, of Harvard.

DR. LORRAIN SMITH, Professor of Pathology at Queen's College, Belfast, who has been recently appointed Professor of Pathology at Victoria University, Manchester, is an *alumnus* of the University of Edinburgh.

It is announced that the King of Greece has bestowed the Gold Cross of the Royal Order of the Saviour upon Sir William Bennett, K.C.V.O., F.R.C.S.

DR. GEORGE F. SHRADY has resigned the editorship of the *New York Medical Record*, after thirty-eight years' service in that capacity. He is succeeded by his former assistant editor, Dr. Thomas L. Stedman.

MR. J. HENDERSON SMITH, M.B. Edin., has been appointed to the Philip Walker Studentship in Pathology at Oxford University for a period of three years.

CHARLES GIBSON, M.D., has been recently commissioned by the Lord Chancellor as a Justice of the Peace for Harrogate.

DR. D. J. COFFEY, Professor of Physiology at the Cecilia Street School of Medicine, Dublin, was presented by the Keating Branch of the Gaelic League with a handsome collection of Gaelic works, on the occasion of his recent marriage. The books consisted of Dr. O'Donovan's edition of the "Annals of the Four Masters," and Sir O'Grady's "Silva Gadelica."

MR. JOHN TWEDDY, President of the Royal College

of Surgeons of England, has promised to take the chair at the annual dinner of past and present students of the Medical Faculty of University College, London, on Monday, October 3rd.

THE Paris Municipal Council has voted a grant of £120 to Professor Grancher in furtherance of his researches as to the means of preventing tuberculosis in schools.

### Special Correspondence.

[FROM OUR SPECIAL CORRESPONDENT.]

#### BELFAST.

RESIGNATION OF PROFESSOR LORRAIN SMITH.—The members of the medical profession in Belfast have heard with great regret that Professor Lorrain Smith is resigning the chair of Pathology in Queen's College, having been appointed to Owens College, Manchester. Though some formalities remain to be carried out before the actual resignation takes place, it is understood that Dr. Smith will leave Belfast before the winter session opens. He came to Belfast about eight years ago as Lecturer on Pathology and Bacteriology, and when the late Sir James Musgrave founded the chair of those subjects, Dr. Smith was its first occupant. His keen interest in scientific medicine has made his name well known far beyond Ulster, and his great personal kindness and readiness to help in every way in his power have made him a universal favourite in the profession. Considering the intimate relations which subsist between the leading pathologist of the school and its other members in the city, the choice of his successor must be a matter of deep interest to them. It is believed that Dr. Thomas Houston will be a candidate for the chair. He has been for several years Professor Smith's right hand man, while he has held the Royal University Studentship in Pathology, and the British Medical Association Research Scholarship. His excellent work on the blood in pernicious anæmia and allied diseases has attracted much attention, and his candidature for the chair is favourably commented on by the members of the Belfast school.

THE SMALL-POX OUTBREAK.—Small-pox has now broken out in a number of towns in Ulster, as was only to be expected when it was prevalent in Belfast. So far, the worst town is Armagh, where there are fourteen cases under treatment, as well as a number of suspects under observation. The beds in the small-pox hospitals are all occupied, and if any further cases occur they will be treated in the wards of the fever hospital. A case was discovered in Clones and removed to the fever hospital, where the patient died. Cases have also occurred in Omagh and Monaghan. There was only one new case in Belfast last week, and none for a fortnight before, so the worst of the outbreak seems over as far as this city is concerned.

The annual report of the President of the Queen's College, Cork, has been issued during the past week. The report states that the number of students attending the College during the last session was 225, as against 190 during the session 1902-3. The number of new students was 68, of whom 52 came from the Royal University of Ireland, 9 from other colleges and universities, while 7 were not matriculated. The President alludes to the great improvement that has taken place in the pathological department since the appointment of Dr. Moore as Lecturer in Pathology. The latter gentleman has instituted post-graduate classes in addition to reforming the method of teaching. The President has, however, to regret that there is a decided indisposition on the part of students of the college to read for honours at the Royal University examinations. It appears that the claims of the College to obtain an examinership in chemistry at the Royal University have been laid before the Senate, but that so far the claims have not been satisfied, in spite, as the President points out, of the unquestioned distinction of Dr. Dixon, the Professor of Chemistry.

[We do not hold ourselves responsible for the opinions of our Correspondents.]

## THE DIMINISHING BIRTH-RATE.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Challenged with having stated that "in 1884 the total birth-rate stood at 31," whereas the birth-rate of England and Wales of that year was 33·6. Dr. Walsh explains that it was the birth-rate of the United Kingdom, and not that of England and Wales, that he quoted. But that will not do, for the birth-rate of the United Kingdom for 1884 was 32·2 and not 31, and was lower than that of England and Wales only by the inclusion of Ireland which, as Dr. Walsh very well knows, has always, for special reasons, had a birth-rate much lower than the other parts of the United Kingdom. In 1884 the birth-rate for England and Wales was 33·6; that of Scotland 33·7, that of Ireland 23·9. The argument which Dr. Walsh founded on the assumption that the birth-rate in 1884 was only 31·0 therefore falls to pieces.

Dr. Walsh falls into other extraordinary blunders. Let me give one as an example: he actually declares that had there been no decline in illegitimacy "we should have had a birth-rate of practically 30·0 in 1904, compared with 31·0 in 1884." I have unfortunately no fore-knowledge of what the returns for 1904 may be, and for the moment I have not access to the vital statistics of the United Kingdom, but the figures for England and Wales for 1902, when compared with those for 1884, are strangely at variance with Dr. Walsh's allegation. Leaving illegitimate births out of the question, the birth-rate for 1884 was 32·0, and for 1902 it was 27·4. During the period covered by these dates the illegitimate birth-rate fell from 1·6 to 1·1, and it has therefore affected the general birth-rate to the extent of 0·5, so that if there had been no decline in illegitimacy the general birth-rate would have stood in 1902 at 29·0, against 33·6 in 1884. This is apparently what Dr. Walsh calls "not far off a level." But all that Dr. Walsh says about the illegitimate birth-rate really strengthens Dr. Taylor's position and weakens his own. Be the fall in that birth-rate what it may, it may be due to the increasing morality of our people, but it may also be due to their increasing addiction to those practices which Dr. Taylor has denounced, which are more likely to be resorted to outside wedlock than in it. The loose way in which Dr. Walsh handles figures puts him almost outside the pale of statistical controversy.

Referred to the Report of the Royal Commission on the Decline of the Birth-rate and on the Mortality of Infants in New South Wales, Dr. Walsh disposes of it by a novel and elegant metaphor, affirming that "Social and economic conditions in New South Wales and in the Mother Country are as chalk is to cheese." They who know our Premier Colony a little better than he does will probably assure him the difference between it and the Mother Country is not greater than that between Cheddar and Double Gloucester, and that human nature in its sexual relations is pretty much the same in London and Sydney. At any rate, he should study the Report, a most weighty and convincing public document, in which he will find a complete and crushing refutation of some of his own fallacies. The Commission, composed of fifteen of the most eminent men in New South Wales, included six medical men, and took the evidence of all the leading members of the profession in the colony. The conclusions at which it has unanimously arrived are well calculated to disturb the smug complacency in which Dr. Walsh would have us wrap ourselves up.

I am, Sir, yours truly,

August 19th, 1904.

LL.D.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—So much has been already written on this very important, I might venture to say *national*, subject

that it is almost impossible to add aught thereto that has not been already said by previous writers. Perhaps, however, you will permit me to preface the brief remarks I propose making by giving the Registrar-General's summary for the last week for London. It runs thus:—"Allowing for increase of population, the births were 39·4 and the deaths 33 below the average." Similar official reports are given weekly, varying only in numbers, from which it is proved to demonstration that a diminishing birth-rate is a reality and not a fiction. The same may be affirmed without contradiction of the death-rate, so that the loss on the one hand is counteracted to a certain extent by a gain on the other, which gives us a greater proportion of adult to infant life. "So far so good," but a continuation of these proportions must necessarily be limited, and a diminishing birth-rate eventuate in a greatly reduced manhood. Of course, it may be said that the Metropolis is not the United Kingdom, and that for accurate comparison statistics of the whole should be given; but as Greater London contains a population of about one-sixth of the home territory, it may be admitted as a fair basis to go upon. We then arrive at the two points of discussion: First, Dr. Taylor's contention that there is a serious and continuous falling off in the birth-rate, attributable to the prudential motives of modern married folk, which will eventually prove destructive to the British race; secondly, the view held by Dr. Walsh and others that this diminution applies to extra-marital as well as marital conditions, and is only in part due to preventive practices. Other correspondents, again, think prevention is incumbent upon, nay, even necessary to, the well-being of the nation at large. I candidly confess my sympathy with Dr. Taylor's view, believing as he does that a stagnant population becomes a decadent one. Present indications, however, hardly point to this conclusion, but rather to degeneracy than disease; and herein there opens up a wider and more absorbing question than the mere increase or decrease of births, the solution of which the Government and thoughtful minds generally are now endeavouring to read. Unfortunately the decreasing birth-rate is clearly traceable to the ranks of the great middle-class, whose ancestors made our nation strong; whilst the feeble, the degenerate and the criminal sections increase and multiply regardless of consequences, and in this lies the national danger. On prudential grounds individualism is justified in not bringing more children into the world than parents can reasonably hope to keep and educate; but such motives, commendable as they are in the abstract, are entirely one-sided and tend to the ultimate replacement of the morally and physically strong by the mentally and physically weak.

I am, Sir, yours truly,

CANTAB.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—I have watched from my obscure corner in this great city the Titanic combat at present being waged in your columns, and much as I sympathise with Dr. Taylor's good intentions, I must confess that it seems to me the honours of the contest fall to Dr. Walsh. May I put the matter into what I conceive to be a logical nut-shell? Dr. Taylor has laid down a universal affirmative proposition—artificial prevention is anathema under all circumstances. You have received letters from two correspondents—"A Country Practitioner" and "A Poor Curate's Wife." These letters give concrete examples of particular cases which appear (to me) to conflict with Dr. Taylor's proposition. Will Dr. Taylor tell us, without circumlocution or qualification, whether:

(a) "Country Practitioner" (to whom a wife was practically a necessity) and "Poor Curate" (whose marriage certainly relieved him from the sin of committing adultery in his heart) did wrong to marry?

(b) If they did right, or, at any rate, finding themselves married at the present time:—

1. Should they seek to bring as many children as possible into the world?

2. Should they use artificial means to prevent or limit conception?

3. Should they persistently violate their natural instincts and abstain from doing what marriage (*vide* the opening sentences of the marriage service in the Prayer-Book) was ordained for?

If Dr. Taylor will be good enough to answer these questions I for one shall respect his motives, even if I do not approve of his judgment.

I am, Sir, yours truly,

QUALIFIED ASSISTANT.

Glasgow, August 20th, 1904.

#### EXPERIMENTAL TREATMENT OF CANCER.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Dr. Skene's Keith's article recently published in your columns gives an excellent summary of the present position with regard to the treatment of cancer, although, from my point of view, he is too pessimistic with regard to the future possibilities of radio-active methods. I am somewhat surprised, however, to find that Dr. Keith has omitted to publish full details of his method. He merely states generally that he has obtained good results from the hypodermic administration of certain substances. The omission of this particular information in an article published in a scientific journal must clearly have been due to an oversight. It is inconceivable that a gentleman of Dr. Keith's standing could knowingly have violated one of the most stringent traditions of professional conduct. Meanwhile, we are all most anxious to know what is the substance that in Dr. Keith's hands has relieved the sufferers from a terrible malady.

I am, Sir, yours truly,

Bexhill, August 16th, 1904. DUNS SCOTUS.

#### EPIDEMIC DIARRHOEA AND DIRTY FEEDING-BOTTLES.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—During the past three weeks we have had many cases of diarrhoea and vomiting occurring in children, mostly between the ages of one and three years. I think that we are too prone to attribute these attacks to the addition of preservatives to milk, when possibly, by personal investigation, we might discover a simpler cause. During the past week I have seen seven cases of sickness and diarrhoea occurring in children aged from six to eighteen months. In no fewer than five cases an examination of the feeding bottle revealed the cause. The bottle itself was in a filthy condition, and the milk curdled in three cases. In two cases in which bottles with a long rubber tube connected the bottle with the teat, although the milk in the bottle was perfectly sweet, the tubing stank horribly, and thus the milk, on passing through, became contaminated. A preliminary purge and careful supervision of the bottles ended in rapid recovery. It would be an excellent step towards checking these epidemics of diarrhoea in infants if we could (1) Abolish the use of the feeding-bottle with long septic rubber channels for the conduction of the milk; (2) if we could impress upon all mothers the necessity of thoroughly cleansing the bottles after each feed. In two of the cases the tubing was absolutely black with flies, which doubtless aided the contamination. I think in the present day we are too apt to pass over the more common causes of disease, attributing it to some cause which is uppermost in the public mind through articles in the lay press.

I am, Sir, yours truly,

S. J. ROSS, M.D.

Bedford, August 22nd, 1904.

#### Royal Colleges of Physicians and Surgeons in Ireland.

THE preliminary examination for the Conjoint Diplomas of the Royal Colleges of Physicians and Surgeons in Ireland is fixed to take place on Monday, September 26th. Entrance forms and medical students' guide now ready.

## Obituary.

### SURGEON-MAJOR GENERAL TIPPETTS.

SURGEON-MAJOR GENERAL A. M. TIPPETTS, late of the Army Medical Service, has died at Southsea at the age of seventy-two. He qualified as a member of the Royal College of Surgeons in 1853, and joined the Medical Service of the Army as an assistant surgeon in April, 1854, serving in the Eastern campaign of that and the following year with the 7th Fusiliers. He took part in the affair of Bulganac, in the battles of Alma and Inkerman, and in the siege of Sebastopol, for which he had the medal with three clasps and the Turkish medal. As a surgeon-major he also took part in the Afghan War of 1878-80, accompanying the expeditions into the Bazar and Hissarik Valleys, for which he was mentioned in despatches and received his second medal. He became deputy surgeon-general in November, 1884, and retired in April, 1892, as a surgeon-major-general. Major-General Tippetts had been in receipt of a distinguished service reward since October, 1901.

### MR. D. A. HUGHES, M.R.C.S.

As the Great Western 12.15 train was about to leave Barmouth Junction one day last week, Mr. D. Arthur Hughes, a well-known medical practitioner at Barmouth, was observed to be running to catch the train. He reached a carriage-door and fell exhausted. He was put into a compartment, but when the train arrived at Barmouth life was pronounced to be extinct. Deceased held the post of Medical Officer of Health for the united districts of Barmouth.

## Literature.

### ANDREWES' DISINFECTATION AND STERILISATION. (a)

THIS work, the author tells us, is primarily intended for nurses and for medical men who have had no opportunities for systematic bacteriological study. "The book is written for those who know no bacteriology, but who need sufficient acquaintance with its principles and methods to be able to understand what they are doing when they attempt to carry out processes of disinfection." We consider that the author has succeeded in carrying out this aim, that the book is a timely contribution to science, and should appeal to those who have to carry out disinfection practically.

The work is divided into two parts, the first of which is comprised in ten lessons, of which the first is introductory and deals with the nature of bacteria, yeasts, and moulds, the second with the growth of bacteria and their distribution in Nature. Following this is an account of the chemical activities of bacteria and their power of producing disease. The fourth section deals with cultivation in artificial media, and section five deals with the thermal death-point of bacteria.

Disinfection by chemicals is considered in section six, and the two following sections are concerned with aerial disinfection and the sterilisation of fluids, and disinfection in surgery and midwifery. Sections nine and ten contain accounts of the nature of contagion and the various specific bacteria.

In Part II we have an excellent account of exercises and demonstrations of a highly valuable and practical character. In the section dealing with disinfection by heat the author explains the difficulty of disinfecting large masses of tightly-packed material, such as horse-hair, and mentions that some steam disinfectors have an arrangement whereby the air is exhausted from the material to be disinfected before the steam is admitted. The importance of this is not by any means clearly explained, as the removal of the air is of the greatest consequence, and, in fact, makes all the difference between the effective action or otherwise of a steam disinfectant. The Washington Lyon Disinfectant is illustrated, but the Thresh and the Equifex types are not, though they both possess the advantage that the

(a) "Lessons in Disinfection and Sterilisation." By F. W. Andrewes, M.A., M.D. Oxon., F.R.C.P. Lond., D.P.H. Cantab. Pp. 292, with 31 illustrations. Price 3s. net. London: J. and A. Churchill.

residual air is removed to a degree seldom attained by the Washington Lyon machine as ordinarily used.

In section six, disinfection by chemicals is considered, and the author very rightly insists on the necessity of a *given strength* and a *given time* for any particular chemical to be able to kill bacteria.

In fact, the whole of this section shows the most careful consideration, and should be read several times by the student of disinfection. We would specially commend (on page 89 *et seq.*) the paragraphs dealing with the criteria by which a disinfectant should be judged for practical purposes.

Pages 190-198 contain an excellent account of chemical disinfection, and the student who desires to follow up this most entrancing and important subject can find full details to guide him in the classical work of Rideal and Ainslie Walker, who have now succeeded in placing this difficult subject on a proper footing.

Dr. Andrewes' work is commendably free from quotations of contradictory experimental work on the germicidal action of various chemicals and proprietary articles, which are usually found to the perplexment of students.

The experiments on testing the power of disinfectants, described by Dr. Andrewes, are well detailed, but it may be doubted whether the organisms mentioned (*Staphylococcus pyogenes aureus* and *Coli communis*) are so suitable as *Bacillus typhosus*.

The book concludes with practical tests of disinfection, the testing of filters, &c., and we are satisfied that it meets a need which is a real one, namely, while moderate in price and simple in language, it affords an intelligent explanation of the why and wherefore of the problems of disinfection in general.

It should appeal in particular to practitioners in the country and to hospital nurses.

#### GALBRAITH ON EPOCHS OF WOMAN'S LIFE. (a)

THE four epochs discussed in this manual are maidenhood, marriage, maternity, and the menopause. It is a little difficult to determine the precise class of reader for whom the book is intended. Much of it consists of sensible advice which all women might with profit read and follow; on the other hand, a good deal is more suited to the medical than to the lay reader, with regard to both the technical character of the phraseology and to the nature and extent of the subjects treated of. The best section of the book is that on maternity; the least satisfactory is that on marriage. The authoress has evidently set out with the intention of inculcating higher ideals in the married life, and she points out the disastrous effects of excesses. There is no doubt that it is of the greatest importance that women should know more than they generally do about the ethics of the marriage state, and we cannot therefore but commend the authoress' intention; but this section would be improved if it were considerably condensed. We could wish that the authoress would somewhat recast the book, so as to make it frankly a book for the ordinary woman rather than for the medical woman, omitting at the same time much of what we must regard as unnecessary detail.

#### AIDS TO SURGERY. (b)

THIS book, which is one of the Students' Aids Series, is intended as a help for students preparing for examinations. We can strongly recommend it to the busy student for this purpose, for it is complete, thoroughly up to date, and the whole subject is condensed into a sufficiently small volume to fulfil its object without at the same time omitting anything of importance. The only point we can take exception to is the paragraph on actinomycosis, where the author conveys the impression that it is not a dangerous disease, for he says: "Large doses of potassium iodide, up to one drachm doses three times a day, for prolonged periods, will cure

(a) "The Four Epochs of Woman's Life: a Study in Hygiene." By Anna M. Galbraith, M.D. Second Edition. Philadelphia: Saunders and Co. 1903.

(b) "Aids to Surgery." By Joseph Cuning, M.B., F.R.C.S. Eng., Senior Resident Medical Officer, Royal Free Hospital, Pp. 394. Price 4s. 6d. London: Bailliere, Tindall and Cox. 1904.

these cases. In addition, if the sinuses are in a position where vigorous scraping can be done the process of cure is hastened."

#### WATSON'S EXAMINATION OF THE URINE. (a)

THIS little book is intended for nurses; the author says:—"The examination of the urine is not of necessity required of the nurse, but it is advisable that she should have an elementary knowledge of urine testing, since she can often put such knowledge to use and assist thereby the doctors under whom she is working."

The book is divided into three parts, the first gives an elementary knowledge of the organs which are concerned in the excretion of urine; the second deals with the physical characters in health and disease; the third with the collection and examination of the urine. The various tests are described simply and clearly, and a table is given showing the more important characters of the urine in some of the commoner diseases. The book is one which should prove a useful addition to the nurse's bookshelf.

#### BROWNE AND STEVENSON ON SQUINT IN CHILDREN. (b)

THIS little volume is an interesting and thoughtful contribution to the subject of convergent strabismus in childhood, and will repay perusal. The authors strike emphatically the true note in the preface, where it is said, "That which has borne the test of years, and is well established, is of more value in practical medicine than yesterday's inventions, which may be failures." Nothing could be truer of much of the so-called medical advance in the present day than this. There is the feverish rush to bring out "hall-baked" theories, and to introduce novelties in ideas and practice, merely for the sake of the notice which they may attract. On the other hand, it is nowadays but seldom that a well-digested contribution to medical literature, based upon the past experience of many years, and enriched with valuable suggestions, comes under the notice of the reviewer. In this category, however, the volume before us should be classed. The scientific etiology and treatment of this deformity have only of late received the attention which their importance deserved, mainly, no doubt, on account of the good results which the empirical method of treatment, introduced by Dieffenbach, of dividing the internal rectus, were instrumental in obtaining. That something was wrong in this form of treatment, however, was often in earlier days proved by the subsequent divergence which ensued as the result of the operation. The tendency in the present day is to avoid operative interference in case of convergent strabismus in children as much as possible, and in this book the reasons for this plan of practice and the methods by which it can be accomplished are clearly and convincingly laid down. To general practitioners, by whom, no doubt, the early stages of convergent strabismus are frequently first seen, this book should prove invaluable for the sound advice it contains on the subject, but ophthalmic surgeons also will find in it hints here and there which will repay them for its perusal.

#### JULER ON OPHTHALMIC SCIENCE AND PRACTICE. (c)

IN this new edition—the third—of his work, the author informs us that the text has been revised, but he does not point out, for the assistance of the reviewer, in which special directions additions and improvements have been effected. We observe that he still retains the obsolete expression "strumous," and speaks of "strumous" keratitis. Inasmuch as the word "strumous" has now no significance as a systemic

(b) "Squint Occurring in Children: an Essay." By Edgar A. Browne, F.R.C.S. Edin., assisted by Edgar Stephenson, M.D., M.Ch. Aberd. London: Bailliere, Tindall and Cox. 1904.

(c) "A Handbook of Ophthalmic Science and Practice." By Henry E. Juler, F.R.C.S. With Illustrations. Third Edition; Revised and Enlarged. London: Smith, Elder and Co. 1904.

condition in general medicine and surgery, how can it be correct to use it in the special departments of our art? The so-called "strumous" keratitis is merely phlyctenular keratitis, aggravated by a septic condition of the conjunctival sac, which is the common feature of "poor and ill-fed," and consequently neglected, children. In the operation of tattooing the cornea, the author recommends the use of epilation forceps for fixing the globe. Epilation are certainly better than fixation forceps, but it is much better to use no forceps at all, the fingers being all that are necessary for the purpose. Detailed criticism, however, is superfluous in respect to a work whose popularity has been proved by the fact that it has reached a third edition. We can cordially recommend this handbook as a useful, practical guide to ophthalmic science; it represents much matured experience on the part of the author, and the present edition has been enriched by some excellent plates, illustrating the normal and pathological histology of the eye, contributed by Mr. George S. Keeling in an appendix.

## Medical News.

### West London Medico-Chirurgical Society.

The following gentlemen have been elected officers and members of Council of this Society for 1904-1905:—  
 President: Mr. C. M. Tuke.\* Vice-Presidents: Mr. C. B. Keetley, Mr. W. P. Barrett, Dr. G. H. D. Robinson, Mr. J. R. Lunn, Dr. E. Furniss Potter, Dr. E. Bromet,\* Dr. G. P. Shuter,\* Mr. H. Webb,\* Council: Mr. R. Pollock, Dr. A. M. Ross Sinclair, Mr. G. A. Garry Simpson, Mr. Percy Dunn, Mr. McAdam Eccles, Mr. E. P. Paton, Dr. A. Saunders, Dr. A. J. Rice Oxley, Dr. J. A. Mansell Moullin,\* Dr. A. Morrison,\* Dr. A. E. Russell,\* Dr. C. Buttar.\* Treasurer: M. T. Gunton Alderton. Secretaries: Dr. Andrew Elliot, Dr. W. H. Walter.\* Librarian: Mr. H. W. Chambers. Editor of Journal: Dr. Leonard Dobson. Editorial Secretary: Mr. J. G. Pardoe. \* Did not hold similar office last year.

### Chloroform Fatality.

A WOMAN, aged thirty-three years, was admitted to the Dalston Hospital, London, last week suffering from appendicitis. Two and a half drachms of chloroform had been administered previous to operation, when she died. After death she was found to have fatty degeneration of the heart.

### Sanitary Reorganisation for the Army.

SIR GILBERT PARKER last week asked the Secretary of State for War whether a scheme for sanitary organisation had yet been prepared for the army or proposed by the Medical Advisory Board; if so, whether there was included in it the sterilisation of all fluids employed as drinks at manoeuvres, on service abroad, and during active service, and by what means this sterilisation was to be secured; whether steps had been taken to secure the instruction, practical training, and examination of non-medical officers of all ranks, in their respective units or commands, in methods of camp sanitation, especially with a view to the prevention of enteric fever, dysentery and cholera; and whether, after such training and examination, the comparative responsibility of such non-medical officers for the occurrence of these diseases in their respective commands or units was to be recognised. Mr. Bromley-Davenport, replying for the Secretary of State, said that the Board recommended the appointment of special sanitary officers to army corps and commands, and there were eleven of these appointments at home and eight in Egypt and Colonies, in addition to the five already existing in India. Instructions regarding the sterilisation of all fluids employed as drinks which are applicable to manoeuvres, service abroad, and active service had been included in the manual of combined training; heat, and in some cases filtration, were the means recommended. Lectures were regularly given to cadets at Sandhurst and Woolwich, and a more advanced course in military hygiene was provided for officers at the Staff College. Instructions in hy-

gienic matters were also given by the specialist sanitary officers. The regulations were also being revised in the direction of devolving more responsibility upon non-medical officers in the supervision of sanitary services in barracks and camps.

### The Plague.

THE following telegram from Lord Milner was received at the Colonial Office on August 6th:—"My telegram of July 31st, No. 211. Plague return should have been no change. As there has been no change since July 9th, no further telegrams will be sent unless recrudescence occurs." A further telegram from Lord Milner, received on August 13th, says:—"Transvaal is now officially certified as clean of plague in terms of Venice Convention." The following telegram has been received at the Colonial Office from Sir M. Nathan, Governor of Hong-Kong:—"Five cases of plague, five deaths, for the week ending August 13th."—*Times*.

### Wills and Bequests.

SIR JOHN SIMON, K.C.B., of 40 Kensington Square, formerly consulting surgeon at St. Thomas's Hospital, left estate, so far as can at present be ascertained, valued at £26,635 gross, with net personality £26,545. Subject to numerous annuities to relatives and friends, and the life interest in a special trust fund of his adopted daughter, the testator left the ultimate residue of his estate to St. Thomas's Hospital, and should the income of the said special trust fund exceed £300, then the surplus is also to be paid to St. Thomas's Hospital.

### Forty Thousand Deaths from Cholera.

NEWS from the cholera districts of Persia is reassuring. The disease has wholly disappeared in many places, and is losing its malignancy in all. But in Teheran between twenty and twenty-five thousand deaths occurred during six weeks, and in the environs about the same number. At present the mortality from that cause in the capital is computed at thirty-five daily, whereas the environs are exempt from the scourge.—*Daily Telegraph*.

## PASS LISTS.

### Royal College of Surgeons, England.

THE following candidates, having passed the necessary examinations, have been admitted members of the College. The names are arranged alphabetically: F. Alcock, E. F. Alford, H. R. Allingham, J. Ayles, F. Barnes, C. E. Bartlett, J. E. L. Bates, L. Bathurst, J. H. Bletsoe, H. G. W. Beckett, H. J. Brewer, F. M. Boclet, J. Bowen-Jones, F. A. Brodribb, E. M. Brown, F. M. Bulley, W. Byam, P. D. MacI. Campbell, T. W. Chaff, J. R. A. Clark-Hall, C. Colmer, G. H. Colt, P. C. Coombes, H. Cooper, W. F. Corfield, W. I. Cumberlidge, F. W. Daniels, W. B. Davy, W. R. E. Drawbridge, E. P. H. Dudley, H. D. Duke, H. E. Dyson, W. S. Edmond, N. C. Fletcher, T. H. Fowler, H. Frankish, J. D. Galloway, H. T. George, S. H. Gibson, H. J. Gibbs, D. R. Gilder, J. L. Gilkes, J. W. F. Gillies, F. G. Goble, R. E. G. Gray, M. Greenwood, P. Gully, C. M. Halsall, J. M. Hamill, R. O. Handcock, A. E. Hay, A. L. Heiser, J. W. Hele, F. C. Hepburn, G. W. Heron, E. C. Hughes, H. Irving, S. D. Jacobson, T. Jays, H. A. Kisch, H. H. Jenkins, O. S. Kellett, W. R. Kirkness, J. L. Lawry, H. Leach, H. C. Lees, G. M. L. Lester, T. Lewis, E. G. R. Lithgow, J. H. McAllum, E. J. C. McDonald, G. H. McLaren, J. B. McVail, H. T. Mant, P. J. Marett, W. N. May, W. O. Meck, R. Milne, E. L. Moss, R. C. Mott, M. J. Motttram, B. N. Murphy, F. Neale, H. Nicol, S. A. Owen, G. R. Painton, W. F. Peach, E. G. Perodeau, E. E. M. Price, T. P. Puddicombe, C. E. Reynolds, R. I. Ritchie, T. H. F. Roberts, G. C. F. Robinson, W. E. Robertson, E. J. H. Rudge, A. P. Salt, H. B. Scott, T. Sanders, S. G. Scott, P. H. Seal, A. W. K. Straton, K. Takaki, A. Withead-Smith, H. M. Thomas, H. S. Turner, M. K. Varughese, W. T. Wallace, H. B. Walters, C. S. White, H. T. M. Wilson, K. S. Wise, and S. C. Yin.

## Notices to Correspondents, Short Letters, &c.

**CORRESPONDENTS** requiring a reply in this column are particularly requested to make use of a *distinctive Signature or Initial*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

**ORIGINAL ARTICLES** or **LETTERS** intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

**CONTRIBUTORS** are kindly requested to send their communications, if resident in England or the Colonies, to the Editor at the London office; if resident in Ireland, to the Dublin office, in order to save time in re-forwarding from office to office. When sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

**REPRINTS.**—Reprints of articles appearing in this journal can be had at a reduced rate providing authors give notice to the publisher or printer before the type has been distributed. This should be done when returning proofs.

**M.D., Vict.**—The Annual Report of the Reg.-Gen. for England and Wales for 1902 is now published and in it you will find the information you require. The births registered in the two countries for that year were 940,500, equal to an annual birth-rate of 28.5 per 1000 of the population. The figures are identical with those of the preceding year, but show a fall of 1.1 when compared with the ten-yearly average for 1892-1901.

**DR. FITZGERALD.**—The finding of the Court was in our opinion more than justified. The thinking medical man should find no little food for reflection in the conflict of scientific evidence. One set of witnesses swear that disastrous effects are produced on lower animals by the administration of a particular drug. Another set of experts testify that the ordinary medicinal dose of that substance is far larger and that it is administered over long periods. Can any candid practitioner seriously defend the use of such a remedy under these conditions? Yet precisely similar remarks apply to various drugs in daily use.

**M. B. (Worcester).**—Is thanked for his letter and appreciation of policy. The diminishing birth-rate as a subject for discussion is looked on askance by most of the medical journals. It nevertheless involves the very foundations of our social system. There is no reason why the medical profession should not investigate in a calm and scientific spirit, the laws that determine the rise or fall of the national birth-rate. Hardly any subject could be of greater definite and vital importance to the community.

### A DAILY MEDICAL JOURNAL.

A **LAY** contemporary announces that a daily medical paper, which is to be made up of six pages of ordinary newspaper size, is to appear in New York, and that a first edition of 100,000 copies has been already subscribed for. What a rich feast of symptoms that 100,000 must be looking forward to! Strangely enough, the chosen home of the patent medicine is not the first country to possess a medical "daily," America having been preceded on this occasion by Italy, where the "Riforma Medica" is published.

**A. B. C.**—We fear there is no other course open to our correspondent but to pay the tax.

**MR. E. WATSON.**—The city which has the largest population next to London is New York, and not Paris as is generally supposed. For further information on populations, see reply to Mr. R. Stevens in our last issue.

### NATIONAL DEGENERATION.

As a contribution to the moot question of the degeneracy of our race Mr. Walter Burns of Belfast writes us that he is now 80 years of age and has "neither gout, rheumatism, pain, nor ache. He can walk as quickly as ever, and has neither shake in his hand nor wrinkle in his skin." He asks "how can the race be anything but degenerate when the large majority of men and women both drink alcohol and smoke tobacco?" He does neither, and says his legacy to his countrymen for health is, "take exercise in the open air every day wet and dry, keep the feet and body dry and the head cool; no heavy dinners, and no heavy suppers, and no alcohol or smoking, and with a fairly good constitution there need be no fear of national decay."

[Probably the possession of a sound constitution has more to do with the robust health of our correspondent than even his abstinence from alcohol and tobacco. We can point to many men of his age equally robust, although non-abstainers, having pursued a simple and healthy course of living.—ED.]

## Vacancies.

**Devon County Asylum.**—Assistant Medical Officer. Salary commencing at £125 per annum, with board and lodgings. Apply to the Medical Superintendent, Asylum, Exminster.

**Carlisle Non-Provident Dispensary.**—Resident Medical Officer. Salary £150 per annum, with apartments (not board). Applications to the Honorary Secretary, G. A. Lightfoot, Esq., 23 Lowther Street, Carlisle.

**Stockport Infirmary.**—Junior Assistant House Surgeon. Salary £140 per annum, with board, washing and residence. Applications to the secretary.

**Macclesfield General Infirmary.**—Junior House Surgeon. Salary £150 per annum, with board and residence at the Institution. Applications to the Chairman of the House Committee.

**Rotherham Hospital and Dispensary.**—Senior House Surgeon. Salary £110 per annum, with board, lodging, and washing. Applications to the Secretary, E. S. Baylis, 19 Moorgate Street, Rotherham.

**Hampstead General Hospital.**—Resident Medical Officer. Salary £120 per annum, with rooms, coals, and gas. Applications to George Watts, Secretary.

**Aberaman, near Aberdare.**—A fully qualified Medical Man to take Charge of a large Colliery District Practice. Salary £400 per annum, with a free house, coal, assistants, dispenser, drugs, &c. No private practice allowed. Applicants must be married. Applications to the Secretary, James Phillips, 10 Pleasant View, Godre Aman, Aberdare.

**Lancaster Royal Infirmary.**—House Surgeon. Salary £100 per annum, with residence, board, attendance, and washing. Applications to the Hon. Secretary.

**Birkenhead and Wirral Children's Hospital.**—House Surgeon. Salary £100 per annum, with board, residence, and laundry. Applications to E. H. Tilby, Hon. Sec., 69 Temple Road, Birkenhead.

**Open-air Sanatorium for Consumptives, Limpley Stoke, near Bath.**—To be opened November next.—Resident Medical Officer. Salary £200 per annum, with annual increment £20 to £200. Experience in Sanatorial Treatment essential. Applications to "Chairman," N.A.P.O., 84 Park Street, Bristol.

**County of London.**—Woman Inspector in the Public Health Department under the Midwives Act, 1902. Salary £150, rising by annual increments of £15 to a maximum of £250. Applications on the official form, to be obtained from the Clerk of the London County Council.

## Appointments.

**MONTGOMERY, ALEXANDER, M.B., B.S.R.C.I.** Medical Attendant to the Royal Irish Constabulary for the C District of Belfast.

**MURRAY, H. L., M.B., B.S. ABERD.** House Surgeon to the Liverpool Hospital for Women.

**NORMAN, A. S., L.R.C.P. Lond., M.R.C.S. Eng.** Certifying Surgeon under the Factory Act for the Havant District of the county of Southampton.

**PERRY, S. HERBERT, M.D. Lond., M.B. Ch.B. Firm., M.B.C.P.** Assistant Physician to the General Hospital, Birmingham.

**RICHARDS, W. HUNTER, M.B., M.S. Durh., M.R.C.S. Eng.** Honorary Consulting Obstetric Physician to the Fowey (Cornwall) Cottage Hospital.

**SMITH, WILLIAM, Medical Officer** for the Hawkesbury, Alderly, Badminton and Acton Turville districts of Chipping Sodbury (Gloucestershire).

**SOPER, GERALD MORGAN, L.R.C.P. Lond., M.R.C.S.** Medical Officer and Public Vaccinator for the Dartmouth and Dittisham Districts of Totnes (Devon).

## Births.

**HULKE.**—On August 17th, at Ivy House, Walmer, the wife of Sydney B. Hulke, F.R.C.S., of a daughter.

**STABB.**—On August 19th, at Harleston, Torquay, the wife of W. W. Stabb, M.D., of a daughter.

**VAUGHAN.**—On August 18th, at St. Petroc, Coalville, Leicestershire, the wife of A. W. Vaughan, L.R.C.P., L.R.C.S., of a daughter.

## Marriages.

**HEAL—TODDUNTER.**—On August 20th, Ambrose Heal, jun., of The Fives Court, Finner, to Edith Florence Digby Toddunter, elder daughter of Dr. Toddunter, M.D., of Orchardcroft, Bedford Park, Chiswick.

**LEGG—MACK.**—On August 18th, at St. Giles, Shermanbury, Thomas Morison Legge, M.D., to Norah Elizabeth, second daughter of J. A. Mack, of The Grinstead, Partridge Green, Sussex.

**STEELE—PARDON.**—On August 17th, at St. Clement's Boecombe, Hants., Charles Hallowell Steele, youngest son of William Stott Steele, M.D., of St. Mary's Church, Devon, to Elsie Joyce Pardon, youngest daughter of John Pardon, Esq., of Culvers, Boecombe, Hants.

**TRUBSHAW—PERKINS.**—On August 18th, at St. Peter's, Pwllheli, Wilfred Trubshaw, Assistant Prosecuting Solicitor to the Corporation of Liverpool, eldest son of Alfred Trubshaw, M.R.C.S., of Pendre, Mold, to Bessie Andre, third daughter of Walter Edward Perkins, J.P., of Bodegoes, Pwllheli, and The Grange, Astwood Bank, Worcestershire.

**TURNER—DENSHAM.**—On August 18th, at St. Luke's Church, Grayshott, Surrey, Francis John Turner, B.A.M.C., son of the late Rev. H. J. Turner, to Mary Theodora, youngest daughter of Benjamin Densham, of Hindhead, Surrey.

**USHER—COMYN.**—On August 18th at St. Paul's Church, Southsea, Lieut. Wm. A. Usher, R.N.R., H.M.S. Apollo, eldest son of the late James Usher, solicitor, Florence Villa, Lurgan, Ireland, to Sophie Honoria, only daughter of Surgeon-General J. S. Comyn, R.A.M.C. (retired), of Woodstock, Galway, and of 21 Ashburton Road, Southsea.

## Deaths.

**ASHER.**—On August 21st, at the Nursing Home, Warrington Lodge, Philip, elder son of the late Asker Asher, M.D., aged 85.

**HENSMAN.**—On August 18th, at Northdown, Margate, Baby, second daughter of Lieutenant-Colonel William Hensman, R.A.M.C., of Cannesfield, Taunton, aged 26.

**STEWART.**—On August 18th at Dunmurry, Sneyd Park, near Clifton, Glo's, Hamilton Stewart, younger son of James Stewart, B.A., F.R.C.P. Ed., of the same address.

## Original Communications.

### THE PREVENTIVE TREATMENT OF SCARLET FEVER

BY ISOLATION (AGGREGATION) HOSPITALS.

By HUBERT E. J. BISS, M.A., M.D. Cantab., D.P.H.,  
Eastbourne;  
Late Assistant Medical Officer, Metropolitan Asylums Board.

#### PART I.

SCARLET fever is a disease of very wide prevalence in this country at the present day. There is no district, urban or rural, that does not suffer to a greater or less extent from its incidence. It is, then, only natural that the community should wish to take steps to rid itself of this malady, especially as it is generally regarded as a highly dangerous one. Some twenty-five years ago, after obtaining the best medical advice, certain towns erected hospitals for the special treatment of infectious diseases, scarlet fever being the one specially aimed at. The idea prevailed at that time that as scarlet fever was infectious by direct or proximal contact, removing the patients suffering from it to a building to which general access was barred would eradicate the centres from which the disease spread. By diligently practising this plan of treatment it was supposed that scarlet fever would either die out or become markedly less. Since the inauguration of this method, urged by the medical profession and pressed by the Local Government Board, nearly every sanitary authority has built a fever hospital. The country, therefore, has had considerable experience of its working, and it may not be out of place to look round at the results that have ensued. To those to whom truth is the prime object to be followed by sanitary as by every other science, it comes as a sad reflection that a proposal to this effect should meet with vehement opposition, but when three or four years ago Dr. Dean Marriott, of Nottingham, and Dr. Killick Millard, then Medical Officer of Health for Burton-on-Trent and now for Leicester, came forward with a good deal of evidence to show all was not going as well with the system as was generally supposed, and suggested more extended inquiry, their proposal was scoffed at. Since then from many quarters further evidence has been forthcoming, and at the present moment the necessity for an inquiry into the fever hospital system, as applied to the preventive treatment of scarlet fever, has been admitted by nearly all the leading organs of the profession, and by many societies of medical sanitarians.

But the demand, for such it really amounts to, has not been sufficiently unanimous to secure its object. To myself it seems a pity that this question should be regarded as polemical; it ought to be looked upon as a strictly scientific one, which if examined on strictly scientific lines must lead to fresh knowledge about a puzzling disease. My present contribution to this debate aims only at suggesting some *prima facie* considerations, first, as to why scarlet

fever *en masse* might be expected to be little amenable to hospital treatment, and, secondly, as to certain obvious disadvantages of the system. I shall confine my remarks strictly to the subject of scarlet fever, for that is the disease which the hospitals were in the main erected to cope with, and which occupies the bulk of their beds. It may or may not be that certain of the arguments apply equally to some of the other infectious diseases, but of them I do not wish to speak. At the same time, it must be remembered that it by no means necessarily follows that because a certain plan of treatment has been successful or unsuccessful with one disease, that it will be successful or unsuccessful with another. Every disease has its own characteristics *en gros*, just as it has *en détail*, and the preventive means appropriate to each will often vary as much as the clinical treatment. No one, for instance, would be found to agree that hospital treatment had been effectual in "stamping out" diphtheria, for it is notorious that that malady has increased by leaps and bounds during recent years. Small-pox, on the contrary, seems to a certain extent to be amenable to institutional influences, but here we have the question complicated by the protection afforded by vaccination.

In writing of an epidemic affection it is usual and convenient to speak of the disease as though it had a separate corporate existence; thus we speak of scarlet fever, diphtheria, and so on, attacking people, invading towns, giving rise to mortality, much as we would of an army or a destroying angel. This is neither correct nor scientific. No disease exists or can exist apart from the patient; the subject in whom the disease manifests itself furnishes by means of the tissue changes wrought in him the *materies morbi* of the disease. But so long as we bear in mind that such is the case, we can speak of the disease objectively considered as "scarlet fever," "diphtheria," or what-not, without violating our pathological convictions. Practically, too, we gain by avoiding cumbersome circumlocutions. Another point I should like to make before passing to my principal thesis: custom and misconception have sanctified the term "isolation hospital" to our institutions for fever patients; common sense and accuracy cannot lend their cachet to the description. An isolation hospital, a hospital where the patient is isolated, does not exist in this country. The fever hospital is an institution where patients are segregated from their fellows and aggregated together, and as it seems to be this very aggregation (want of isolation) that is responsible for much of the mischief of the system, it does not seem fair to speak of an isolation hospital when we really mean an aggregation hospital. There is a real, essential difference.

Now, in order to assess the effect of the aggregation hospital as a factor in scarlet fever incidence, it will be necessary to consider in some detail what is meant by this scarlet fever; what are the characters of the disease as met with when it affects communities and when it affects individuals; we must look at its history, its natural course, and its present condition. These points I should like to review, and further to speak of the necessarily entailed evils of the aggregation policy, but the main topic—the effect of hospital treatment

as a preventive of scarlet fever incidence—I shall leave to Dr. Killick Millard, who has worked so assiduously and energetically at the subject.

I would begin, then, by taking a backward glance over the course that scarlet fever has followed since it appeared in this country. Here, however, one is faced by a great practical difficulty, and one not without its significance; I mean the impossibility of distinguishing scarlet fever from diphtheria and other throat inflammations in the early accounts that have come down to us. We may form theories, hazard conjectures, promulgate views, but in actual fact it is not possible to speak with certainty. The Greek *κυνδύχη*, the Latin "angina," the Spanish "garrotillo," the American "throat distemper," the Irish "plague of the throat," the mediæval "pestitis gutturosa"—all seem in one description to point to scarlet fever, in another to diphtheria, in a third to tonsillitis. Now, a full-blown scarlatina rash is a disease phenomenon at once obvious and striking; the contrast between the rosy, angry skin of scarlet fever and the pale, waxy cuticle of diphtheria would immediately arrest the most casual observer's eye. How, then, does it happen that when we seek to penetrate into the true nature of an epidemic of throat disease as described by the older pyretologists we are lost in an impenetrable jungle?

Is it the physicians were careless and stupid, or is it that two, aye, and three, diseases were often mingled in the same outbreak? Personally, I incline to the latter view, and it is one taken by an epidemiologist of the eminence of Creighton. Doubtless, the clinical manifestations of the two diseases were not at all clearly distinguished, for even after Bretonneau had established the leading features of diphtheria he was forced to protest against his chosen name being used indiscriminately for all diphtheria-like appearances of the throat. It is, however, difficult to read accounts such as those given by Dr. J. Wall and Dr. J. Johnstone of the epidemic of throat-disease at Kidderminster betwixt 1748-50 without the conviction being borne in on one that this outbreak was not a uniform, unalloyed one, but that both diseases played a rôle in it, scarlet fever, perhaps, the more prominent one. The same holds good for many other epidemics, such as the morbus strangulatorius of Starr, in Cornwall, in 1750, the throat-disease of Hexham, in Plymouth, in 1751, the ulcerated or malignant sore throats described by Fothergill, Fordyce, Withering, and others. Hexham, for instance, is quite clear as to the sloughing of the throat and the rash, but he gives a vivid description of the tracheal casts spat up by the patients—an event that never happens in scarlet fever *pur et simple*. Far from this view being an unreasonable one, in the light of what we now know of the cross-infection of patients in hospital, it is an eminently reasonable view. It is probably also the right one. There is another fact that is also most striking in reading the history of scarlet fever, and that is the remarkable variations in the severity of the outbreaks, and even of the same outbreak at different times in adjacent places. Naturally enough the mild epidemics received less treatment at the hands of contemporary writers than the malignant ones, and it is safe to assume that in an age when the *cacothetes scribendi* had not the vogue that it enjoys at the present day, many a mild outbreak passed unrecorded. Still, this difference in type, as it is called, is sufficiently well established by what has come down to us to place it beyond doubt that far from the modern benignity of scarlet fever being an isolated phenomenon, it is quite *en place* with the behaviour of that erratic disease. Examples of malignancy are furnished by the outbreak at Kingston, in New England, in 1735, and the country districts of New Hampshire; in these places it carried off one-third to one-sixth of those attacked, whilst of the 1746 outbreak in Bromley-by-Bow it is recorded that "so many children died suddenly, some losing all and others the greater part of their families, that people were reminded of the plague." On the other hand, the epidemic at Chesham in 1788, described by Ramsey, "carried off but few considering the great numbers

affected by it," and the outbreaks in London, 1807-08 and 1814, are described as being "generally mild, presenting the eruption with slight sore throat." Again in the same epidemic the two types of the disease may be present side by side, as occurred, for example, in an outbreak related by Dr. James Sims in 1798. Much more often an epidemic of considerable malignancy was succeeded by years of wide prevalence of a benign form of the disease. Such a change of type is recorded by Dr. Levison in 1778. The very violent epidemic of scarlet fever which prevailed in London and the surrounding villages in 1777 abated in November, but was succeeded in the following year by a very mild type of the disease that affected many persons. In 1810-11 malignant scarlet fever scourged Nottingham and Debenham, but its virulence abated and remained in abeyance till 1831, though a mild form of the malady was common enough in the interval. The most clear and striking account of this variation in type is the well-known one we read of in Graves' "Clinical Lectures." In that classical work he tells us after the fearful epidemic in 1801-04 in Dublin, "although scarlatina epidemics recurred very frequently during the next twenty-seven years, yet it was always in a simple and mild form." In 1834 the disease again assumed virulent guise, and committed ravages similar to those of 1801. It is in this connection that Graves speaks those pregnant words which will bear quotation even once again. "In spite," says he, "of our boasted improvements, we have not been more successful in 1834-35 than were our predecessors in 1801-02." One cannot help reflecting—Are we any more successful in 1904?

Having seen, then, that it is the habit of scarlet fever to vary widely both in its prevalence and in its character, we may next consider what was the condition of this country with regard to the disease before the advent of the aggregation hospital. Now, after a generation of mild but widely disseminated scarlet fever, the middle of the nineteenth century was characterised by many severe epidemics, and it would hardly be too much to say that between 1840 and 1874 the country was scourged by the disease. The figures for each of the decennial periods 1841-50, 1851-60, 1861-70, and 1871-80 show great mortality from scarlet fever, the highest peaks being reached in 1848, 1858-59, 1863-64, 1868-70, and 1874. In the years 1863-74 scarlet fever was the cause of 4 to 6 per cent. of the deaths from all causes in England and Wales. 1863 was the year of highest mortality with 30,475 deaths, and 1874 the lowest (except 1868) with 24,922. Naturally, scarlet fever became greatly dreaded, and it is not in the least surprising that with this record well within the memory of living people the disease should be regarded as a pestilence to be combated by every available means. But the natural swing of the pendulum, particular virulence abating to give place to wide prevalence of the malady in benign form, took place after 1874, and from that date the mortality has been steadily on the decline—a condition of things that the well-informed epidemiologist could have foretold with no little certainty at the time. It has been claimed that this drop in the death figures was due to the introduction of the aggregation hospital, but this claim can hardly be seriously maintained; indeed, it is not made by the more responsible epidemiologists and medical statisticians. The change of type was, historically speaking, due at the time it set in, as similar changes had been due and had fulfilled their destinies time after time in past years. Moreover, this alteration was not confined to this country alone, but occurred about the same time in America, Germany, and Norway, where the aggregation principle has not been adhered to as it has in Great Britain. It is difficult to see how it can be thought that the establishment of a few hospitals in isolated centres could have affected the type of the disease in its general incidence, for it must be remembered that anything approaching general aggregation in hospital has only been attained during the

last fifteen years or so. The only possible way by which hospitals could reduce the total mortality of the disease would be by a vast superiority of hospital treatment over home treatment. In the absence of any specific treatment for scarlet fever it is not reasonable to attribute any change in mortality to any particular plan of treatment, especially as there is none for which such claim has been made. Comparative mortality figures for home and hospital treatment are difficult to obtain, and for various obvious reasons are open to great fallacy when they are obtained and compared. I have, however, calculated the scarlet fever death-rate for those removed to hospital and for those who remained at home, in London, for the five years 1898-1903. These figures are the largest available; the returns for towns of average size deal with so small a number of deaths that the transference of one or two cases from one column to another affects the percentage very considerably, and gives an erroneous idea of the significance of the factors involved. In taking the figures for London I have not included the cases admitted to the London Fever Hospital, which were few in number, and I have calculated the death-rates on the total admissions to the Metropolitan Asylums Board hospitals, instead of on half the sum of the total admissions, discharges, and deaths as ordered by the Registrar-General. This it was necessary to do in order to make the figures comparable with those of home-treated cases; the difference is very small, and such as it is would make for a higher rate for the hospital cases.

Year.	Notifications.	Hospital Death-rate.	Home Death-rate.
1898	16,894	4'11	1'51
1899	18,089	2'51	1'01
1900	13,800	2'99	1'43
1901	18,381	3'73	1'08
1902	18,252	3'53	1'28

I do not wish to press the significance of these rates unduly. They are subject to selective influences on both sides—the home and hospital; but I think it may fairly be said that they indicate pretty conclusively that there is no general therapeutical gain to patients treated in hospitals even under the very favourable conditions they enjoy in the Metropolitan Asylums Board's institutions. It is as unreasonable to attribute the fall in the death figures for scarlet fever to the institution of aggregation hospitals, as it is to attribute to the same influence the undoubted change in the degree of severity of attacks of the disease which occurred in the last quarter of the nineteenth century. The fall in the death figures is the direct reflection of the change in type of the disease, and both are natural variants in its epidemic history that have occurred wherever the disease has been prevalent for any length of recorded time. The question naturally arises—to what are these changes in the character of the disease due? why is it limited and savage here to-day, wide and benign there to-morrow? Every one of those influences that are supposed to affect the malignancy and benignity of diseases has been canvassed over and over again by epidemiologists, and the net result, honestly stated, is that no one knows. The mystery is just as deep as is that of the original *habitat* of scarlet fever. At the present day we find the disease principally manifesting itself in endemic form in the temperate zones, but it can, and has often, prevailed widely in the tropics. The virus, however, does not find so congenial a *milieu* in the hot and cold climates as it does in the temperate ones; consequently it is more firmly established in those districts of North America, Australia, and Europe which enjoy a mean temperature at neither extreme of the thermometer. But in these districts neither heat nor cold, dryness nor wetness, healthy surroundings nor unhealthy surroundings, richness nor poverty have been shown to exercise any influence on the type of the disease that prevails, or the class of society that it attacks. True endemic scarlet fever has a seasonal rise and fall, in England the maximum height of its curve being attained in the late autumn and the minimum

in early spring. Any help that might be expected from the study of this phenomenon is, however, negated by the paradoxical fact that the New York mortality curve is the inverse of the London one. Attempts to fix the responsibility for the character of scarlet fever outbreaks on this, that, or the other factor have so far been failures. Hirsch, after a critical inquiry, sums up the situation by saying: "We are completely in the dark as to the conditions that make scarlet fever epidemics assume a good or bad type." The same holds good with regard to the conditions that bring about scarlet fever prevalence. Beyond the fact that milk is a recognised agent in sometimes spreading the disease, and that scarlet fever is more common in the fall of the year, our knowledge of the factors that initiate scarlet fever outbreaks amounts practically to nothing. Every variation in the weather and every insanitary condition has been charged at some time or another with the responsibility of setting up epidemics of scarlet fever, but none of these has as yet been shown to be necessary or even determinative, either alone or in combination.

It is only just, then, to admit that whilst of the history and geography of scarlet fever we have a fair amount of information showing the disease to be a very variable one both as to prevalence and intensity, we know nothing of any value of the causes of these phenomena. When, therefore, we essay to fight the disease, we take up arms against a sea of troubles, and it is hardly rational to suppose that with so little information—and that so untrustworthy—of the causes of the malady we can hope to make any successful progress with its preventive treatment. The theory that by removing the personal element of infection we shall eradicate the chief propagating factor of the disease leaves out of account practical difficulties so momentous that it is hard to believe that the advocates of *en masse* removal to hospital could have had much personal experience of the clinical manifestations of scarlet fever. The whole essence of success in the aggregation policy, if it can ever be attended with success, is early and accurate diagnosis, and it is just this early and accurate diagnosis that is one of the most elusive features of scarlatinal infection. The fully-developed case of scarlet fever, with its throat and skin symptoms well marked, causes the average practitioner but little hesitation, but side by side with such cases, and independently of them, occur numerous others in which a little fever or malaise, a fleeting rash, or slight pharyngitis, is all the diagnostician has to guide him. The greater his range of experience the greater is his puzzle, and from the administration point of view he has to choose between certifying dozens of doubtful cases, or leaving half the scarlet fever ones he sees unremoved. Many cases are with our present apparatus undiagnosable, and yet we hear people speak of scarlet fever as if it were as distinctive and recognisable from other maladies as among warships a torpedo-boat is from a cruiser. In medical writings one sees it often stated that the scarlatina of Sydenham is the classical description of the disease, and one is left to deduce that something approaching finality was attained by that admirable physician. But Sydenham does not even mention sore throat as one of the symptoms, and he regarded the malady as a trivial complaint hardly worthy of the name of disease (*hoc morbi nomen, vix enim altius assurgit*)—fatal only through the too great assiduity of the medical attendant. The later writers—Trousseau, Graves, Watson—all recognise the multifarious varieties of scarlet fever, and the difficulty of determining the nature of those slight cases of illness which present no characteristic conjunctions of symptoms. Their *scarlatina latens* finds its modern homologues and congeners in conditions described under various names by various writers. In recent literature one finds *scarlatina sine eruptions*, *scarlatina apyretique*, *scarlatinette*, *ambulatory scarlatina*, *scarlatina minima*—all these terms used to designate those ephemeral attacks which, clinically, are merely interesting, but from the epidemiological point of view disastrous to any "isolation" system. They are perfectly definite,

indisputable occurrences, these attacks, thoroughly well known to an observer of the disease, but often only revealing their nature by collateral or circumstantial evidence. I need not detail their characters; sufficient is it to say that with no criterion to which reference can be made there is not a case of tonsillitis or of erythema of the skin of the chest, that one meets with in every day practice, of which one can say with certainty whether or not it is an instance of scarlatinal infection. Observation will sometimes help to solve the problem, but it has been one's experience time and again to have a suspected patient under daily supervision, and at the end of six or eight weeks to have to discharge him without any satisfactory diagnosis having been made. No system of isolation can afford to neglect these cases. They are as scarlatinal as the most severe attacks, and as instinct with infection. Without presuming any carelessness or want of skill on the part of the practitioner, it seems to me to follow necessarily that if scarlatina is to stand a chance of eradication by isolation, a prodigious number of cases of slight sore throat, of anomalous blushes of the skin, of ill-defined shagginess of the fingers, must be swept into hospital, or a large proportion of actual and potential sources of infection be left to stalk unrestrained through the land. Such a procedure is, of course, impracticable. It would entail imprisonment and serious loss to enormous numbers of persons not suffering from scarlet fever, but whose illness could not be diagnosed with certainty. Any system that seeks to eliminate the personal element in scarlet fever infection must rest for its success on the separation of all cases, or of such a large percentage that a very sensible reduction in the total number of infections would be apparent. Such can never be the case till the diagnosis has improved to such a point that practically all cases, however mild, are recognised and dealt with in hospital or at home. Till some new fact is introduced into our knowledge of the disease, it seems to me impossible to hope for any satisfaction in seeking to control scarlet fever by personal isolation. It is even doubtful in the light of its past history whether individual elimination is likely ever to be of much service as a prophylactic measure. It is axiomatic in most human affairs that the policy of shutting the stable-door after the horse has been stolen is futile.

## HOSPITAL ISOLATION AND SCARLET FEVER:

### THE STATISTICAL ASPECT.

By C. KILLICK MILLARD, M.D., D.Sc.,

Medical Officer of Health for Leicester; late Medical Superintendent, Birmingham Fever Hospitals.

WHILST the question of the utility or otherwise of fever hospitals requires to be carefully looked at from every point of view, it can only be finally settled by appealing to statistics. It is well known, of course, that the use of figures may easily involve fallacies, and so lead to erroneous conclusions, but this is no argument against their legitimate use. As Dr. Newsholme has well said, "While so many are ready to say that 'anything can be proved by statistics,' but few realise that without statistics nothing can be proved, and that unless complete ignorance is to persist, even defective statistics must be used to the full extent of their value."

In the case of hospital isolation the problem specially lends itself to statistical consideration as all the essential data are obtainable. Thanks to compulsory notification, which has now been in force in most of our larger towns for at least ten years, and in many for a much longer period, we know, with approximate accuracy, the number of cases of scarlet fever occurring year by year. The estimated population for each year being also,

of course, known enables us to calculate the attack-rate per 1,000 population, or *prevalence* of the disease, so that differences arising from variations in population are eliminated. The death returns, which go back for a much longer period, enable us to calculate *mortality*, whilst the number of attacks and the number of deaths together yield the proportion of cases proving fatal, or *fatality*.

### METHODS OF USING STATISTICS.

Whilst the essential purpose of all statistics is comparison, there are two different methods of making comparisons applicable to the present problem. The first is to consider each town or district separately, comparing its condition with regard to scarlet fever since the policy of hospital isolation was started with what existed previously. The second is to compare towns with other towns which differ from them as regards the practice of hospital isolation.

The first method is a good one as far as it goes, but it has certain limitations. Thus, in very many towns compulsory notification only came into force simultaneously with, or subsequently to, the practice of hospital isolation, so that in these cases it is impossible to make any comparison as regards the relative prevalence of the disease. Then, in the case of mortality, although this is known for a sufficiently long period, we are met with this difficulty, that *everywhere the mortality from scarlet fever has been on the decline* owing to the change which has taken place in the type of the disease. It is now admitted that this change, from a very severe to a very mild type, has taken place quite independently of hospital isolation, for (a) the change set in about 1860-70—*i.e.*, before hospital isolation was thought of; (b) it has been quite as marked in towns and country districts which have never practised hospital isolation; (c) it has taken place in other countries, including those where hospital isolation is practically unknown.

Unfortunately these facts have only recently become recognised, (a) and many sanitarians, influenced no doubt by a very natural desire to justify the great outlay which the erection and maintenance of fever hospitals entailed, fell into the error of ascribing the reduction in scarlet fever mortality which they observed in towns where hospital isolation had long been practised to result of such hospital isolation.

There can be little doubt that in this way the belief was propagated that the practice of hospital isolation rested on a sound basis of statistical proof. A good illustration of the exaggerated ideas which prevailed only a few years ago as to the results accomplished by hospital isolation is furnished in the Final Report of the Royal Commission on Vaccination. On page 45 the Commissioners say, referring to the decline in scarlet fever mortality, "We think that the steps which have been taken in various ways to isolate persons suffering from scarlet fever have largely contributed to this decline"; whilst in the Minority Report, the dissentient Commissioners go even further, saying, in reference to scarlet fever and some other diseases: "The recent development of proper hospital isolation has been most strikingly effectual in reducing, almost to insignificance, the mortality from these diseases." Such unreserved statements are all the more remarkable in that their

(a) They were clearly pointed out by Dr. J. T. Wilson in 1897, but did not at first receive the attention which their importance merited.

principal expert witness on this subject, the late Sir Thorne Thorne—than whom no one was better qualified to speak—had in his evidence emphatically dissociated himself from these optimistic views, saying: "I know that some people attribute it (the decline in scarlet fever mortality) to hospital influence; but wherever we have been able in a given large town to inquire how far any diminution has been due to isolation, we cannot make out that the diminution has in any sensible way been due to that practice."

It must be clear, from what has been stated above, that a diminution in the mortality of the disease cannot any longer be regarded as evidence of the value of fever hospitals, and the fact that such a serious fallacy was able to exist for many years is certainly rather disquieting.

Turning now to those large towns in which compulsory notification was in force for a considerable period—say ten years or thereabouts—before hospital isolation was begun, or at least before it was practised to any extent, we find *no evidence as regards the prevalence of the disease that any appreciable diminution has occurred.*

Derby, Nottingham, Bolton and Halifax are, I believe, the only towns in this class (among the larger towns), and in none of them can it be said that scarlet fever has shown any real tendency to decrease since the practice of hospital isolation was inaugurated. Among the smaller towns the experience is similar; if there are any exceptions they have not been published. Of course, if too short a period be taken for comparison the result might easily be misleading, for scarlet fever is a disease which naturally tends to fluctuate. Indeed, this tendency to fluctuate is one of the reasons why comparisons made with previous years in individual towns can scarcely be conclusive, especially as the number of towns in which a satisfactory comparison can be made at all is so small.

We must turn, therefore, if we really wish to settle this question, to the second of the two methods referred to—*viz.*, to institute comparisons between different towns—between those which do not isolate at all, or only to a small extent, and those which have practised the measure largely. Now, it is obvious that if the practice of hospital isolation has any marked effect in reducing either the prevalence of or mortality from scarlet fever we should expect those towns which have practised the measure much to suffer less from the disease than those which have neglected it. It would, however, be quite fallacious to pick out for comparison one single town which isolated much and another which isolated little. There might be local conditions in the one town, quite apart from the question of hospital isolation, which would account for a higher scarlet fever prevalence.

It would also be unsafe to take too short a period for comparison, as the presence or absence of epidemics might swamp any effect due to hospital isolation. But both these objections can be got over very largely, if not entirely, by taking a number of towns or districts and grouping them so as to get an average result, each group being made as large as possible, and the period covered as long as possible—at least ten years. To make the comparison still fairer, the larger towns may be considered separately from the smaller, and urban districts from rural. There is an important consideration, however, which certainly ought to

make any such comparison tell in favour of the isolating groups, for we may safely conclude that those towns or districts which have made the most serious and determined efforts to stamp out scarlet fever by "pushing" hospital isolation have also, with very few exceptions, been active as regards other preventive measures as well. Moreover, the mere fact that a sanitary authority picks out one disease for hospital treatment is certainly calculated to raise the importance of that disease in the eyes of the public, and so to make them more careful than they would otherwise be. This is certainly one of the indirect advantages of hospital isolation. On the other hand, those towns which have neglected hospital isolation have also, in many cases, been very backward and indifferent about disease prevention in general.

In spite of this consideration it will be found, if large enough groups be taken—the one isolating, and the other not—that the average attack-rate and mortality over a period, say, of ten years will come out almost exactly the same in each group.

The advocates of hospital isolation object to any comparison being made on the lines we have recommended. Comparisons are proverbially odious—to those who suffer by the comparison—but it is difficult to believe that much objection would have been taken if the isolating towns had shown a marked superiority.

#### THE "CONTROL" EXPERIMENT.

The importance of the "control" experiment is well known to every student of modern science. Without it, it is impossible to determine whether a given result is due to the supposed cause or not; and there are numberless instances where the employment of a "control" has revealed the most unexpected fallacies. In the case of the problem before us, a "control" experiment is furnished by those towns which have refused to follow the prevailing fashion and have not provided fever hospitals, or, where a hospital does exist, have only used it to a very small extent. If we find that in these towns—the bad isolators—the prevalence of or mortality from scarlet fever is, speaking generally, no greater than in the towns which we may regard as good isolators, the obvious conclusion which most unbiassed people must come to is that hospital isolation is accomplishing very little. We are justified in saying that if a non-isolating town builds a fever hospital and enters upon an isolating career it must not expect to see any appreciable diminution in the disease, even in ten or fifteen years' time; and the same applies to towns which enlarge existing hospitals and increase the percentage of cases isolated.

On the other hand, we have good grounds for assuming that if an isolating town were to abandon isolation, partially or even entirely, and utilise its fever hospitals for other purposes, nothing very dreadful with regard to scarlet fever would happen. As a matter of fact, necessity, which has so often been the mother of invention, has already provided several striking examples of this—notably at Oldham, in 1893, in Leicester, in 1892, and again more recently in 1903, and in Derby, in 1903. In these cases, owing to epidemics of small-pox, the fever hospital had to be reserved for that disease, and scarlet fever had to be treated at home—with very satisfactory results!

In this brief article no attempt has been made to give detailed statistics. In the space at our

disposal only selected figures could have been given, and selected figures, which must necessarily be one-sided, are open to objection. The question is too vast and too important to be settled off-hand, but needs to be made the subject of an organised inquiry by an impartial and authoritative tribunal. In the meantime, sufficient has been said to show that there are good grounds for dissatisfaction with the results which are being obtained in return for the great expenditure of public money which the hospital isolation of scarlet fever entails. These results, we may safely say, are very small indeed compared with the sanguine expectations which were raised when the measure was first introduced.

### THE ORGANISATION OF THE BACTERIOLOGICAL SECTION OF THE KING INSTITUTE, MADRAS.

By LIEUT.-COLONEL S. R. CHRISTOPHERS, M.B.,  
Ch.B.,

Indian Medical Service; Superintendent of the King Institute of  
Preventive Medicine, Madras.

AN important circular letter has recently been distributed throughout the Madras Presidency by Lieut.-Colonel W. G. King, C.I.E., I.M.S., Sanitary Commissioner for Madras. It calls attention to the fact that Government has gone to the expense of supplying public facilities for securing bacteriological diagnosis. The laboratory throws open its doors to no less than six qualified medical men who may wish to carry out independent investigations. The bacteriological section is amply provided with requisite apparatus, which will be at the disposal of private as well as of official workers. Lieut.-Colonel King has appended to his letter the following article of mine as explaining the general scheme of the Institute. The departure is likely to interest public health workers at home in the United Kingdom, as well as in tropical countries.

#### I.—PUBLIC HEALTH.

The importance of bacteriological study in relation to sanitation needs no comment. In the large laboratories of Europe, and, indeed, throughout the world, the most diverse investigations in this relation are in progress, and questions regarding the bacteriology of water, milk, sewage and food are constantly being determined. Even agricultural methods and trade processes are becoming more and more based on bacteriological data. In India and the tropics generally, where the bacteriological fauna is very imperfectly known, there lies open an enormous field for research. Properly equipped laboratories are necessary for such work, and a large central laboratory in active working order has an importance scarcely to be over-rated. Such an institution should be the means not only of encouraging, stimulating, and assisting men occupied in private research, but, especially by reporting upon material sent in for examination, should be of use to all engaged in clinical, sanitary, veterinary or medico-legal work.

It will be obvious that the full extent and scope of the work of such a laboratory can only be roughly indicated.

In regard to matters more directly relating to public health we may instance the following as probably embracing the more ordinary investigations likely to be carried on:—

*The Bacteriological Examination of Water.*—The satisfactory condition of a water supply, the efficiency of a filtering system, and such like points can, as a rule, be roughly determined by the local sanitary officer, who can be readily supplied by the Institute with agar tubes and sterile Petri dishes. It will, however, in most cases be unlikely that this officer will have the means of undertaking more than an enumeration of colonies. When, from the number or appearance of

these, suspicion arises as to the presence of contamination, and a further qualitative examination is called for, it can be carried out from samples forwarded to the Institute.

In order that reports on such samples may be of value, it is essential that they should be collected and bottled with the greatest care. The use of an unsterilised bottle may quite prevent any idea being arrived at as to the bacteriological condition of the water when collected. For most purposes, an ordinary small stoppered bottle of a few ounces capacity may be used. It should be immersed in water and boiled for thirty minutes in a covered vessel, which should be kept closed until cool. As soon as the water is cool, the bottle should be emptied and at once closed with the stopper. In collecting samples with the object of testing a water-supply, all the usual precautions should be adopted. In cases where it is suspected that the water contains the cholera vibrio, it is well to include some water from the actual surface instead of, as in most cases, plunging the bottle to some depth before allowing water to enter.

The bottle when filled with water should be at once closed and the stopper firmly tied down. Samples should be forwarded with the utmost despatch. Where possible, the bottle should be surrounded in ice. When this is not obtainable, sawdust packing will serve as a fairly efficient non-conductor of heat. When sawdust is used, the bottle should be carefully wrapped in paper.

*The Bacteriological Examination of Milk.*—Milk suspected of containing tubercle bacilli should be forwarded in a sterilised (boiled) bottle. If possible, the sample should be packed in ice.

Milk suspected of being profoundly contaminated can always be examined bacteriologically and the number of organisms compared with that in ordinary specimens. It is essential in this case that the milk should be forwarded at once and packed in ice.

*The Bacteriological Examination of Sewage.*—Sewage effluents should be sent under similar conditions to those already noted for samples of water. For important investigations on matters relating to sewage the Institute possess a septic tank, filtering beds, &c.

*The Bacteriological Examination of Food.*—Food suspected of causing ptomaine poisoning should be forwarded for examination. Full reasons should always be given for considering the food to be the cause of the outbreak.

*The Action of Disinfectants.*—At a time when disinfectants of all kinds are being advertised, it is important that their efficacy should be proved before they are used. Samples of disinfectants sent to the Institute will be tested as regards their action on micro-organisms. A report explaining their good and bad qualities will be sent at the expiration of the experiments.

*Soil.*—Soil suspected of containing tetanus or anthrax should be forwarded in a jar or wide-mouthed bottle.

*Plague.*—No disease in India is of greater importance to the sanitarian than plague. In no other instance does so much depend upon the detection of the first case in any town or village. In many cases officers, not very conversant with the disease, have to decide whether or not such a case is cholera, and on this opinion may hang enormous potentialities. It is then not a small matter that in every suspicious case of sickness or death a direct answer, as a result of microscopical examination, can be given. The examination of blood is not of much use except in the final stages of fatal cases, but smears from the puncture of swollen glands in the bubonic cases and from sputum in the pneumonic will enable a diagnosis to be at once arrived at. In the case of bodies found dead and suspected of being cases of plague, it is well to send smears of the spleen pulp, as in every form of the disease this organ contains the bacilli.

To enable films for the above purposes to be sent on the least suspicion, slides have been supplied to all medical officers in the Presidency of Madras.

The most satisfactory way of making films of gland

fluid or sputum is by the use of a needle as described later in this paper. When spleen pulp is in question, the edge of another slide will be found most useful. In all cases the slide should be wrapped in clean paper and securely packed.

When plague is suspected in rats, a recently dead animal should be opened and smears made of the spleen, liver and of any inflammatory condition noted.

## II.—CLINICAL DIAGNOSIS.

Routine bacteriological and pathological examinations of clinical material are undertaken at home in several institutions, notably the Pathological Diagnosis Society of London, and a similar one at Liverpool. At the Pasteur Institute at Kasauli also such specimens are received and reported upon. The bulk of material sent to these institutions consists of sputum from suspected cases of phthisis, of blood for the determination of the Widal reaction, and swabs from diphtheritic throats. At the same time, urinary deposits, tumours and many other miscellaneous materials are submitted for report. In starting a similar institution in Madras, we recognise that there is a far wider and more varied field for such work than at home. Malaria, filaria, and other parasitic diseases are enormously prevalent. Tropical medicine indeed largely deals with parasites. Its tendency is to show definite causes for disease in parasites of different nature, both bacterial and protozoal, and to care less for the secondary clinical manifestations. On this account, microscopical and bacteriological methods of diagnosis are becoming necessary. Many diseases indeed are unrecognisable apart from microscopical examination, and the diagnosis of many others must always be uncertain without it. In their differentiation the microscope will play a large part. We may instance in this respect the startling discovery by Donovan of a new disease equal in importance to tubercle or cancer. Spirillum fever can scarcely, as appears at present, be confined to Bombay. It is not by any means certain that human trypanosomiasis is confined to Africa. Such points and the differentiation of entirely new diseases are almost certain to follow upon widespread examination of the blood and tissues of obscure cases. The Institute ought, then, to be of use in the diagnosis of obscure and difficult cases, in still further clinching the diagnosis of malaria and typhoid, and in leading possibly to the discovery of entirely new causes of disease. The field for useful work on these lines is very great, but we may indicate roughly the more usual examinations which it is proposed to make and to report upon.

1. *The Examination of Material for Tubercle, the Gonococcus, the Pneumococcus, the Leprosy Bacillus, the Micrococcus Melitensis, the Vibrio of Cholera, and other well-known micro-organisms.* In this respect the presence of human anthrax should be borne in mind, also that scrapings from ulcers of all kinds are likely to yield in many cases evidence of an unsuspected condition—i.e., leprosy, infection with Donovan bodies, &c.

2. *The Examination of Blood for Specific Serum Reactions.*—For useful purposes these are practically confined to reactions with the typhoid bacillus and the *M. melitensis*. Capillary tubes, &c., can be obtained gratis from the Institute.

3. *The Examination of Films of Blood and Smears from Different Organs.*—It is expected that the greatest help will accrue from the result of blood examinations. By the examination of peripheral and splenic blood it will be possible to determine the presence of the malaria parasite, filaria, Donovan bodies, trypanosomiasis, spirilla, the plague bacillus, the Malta fever organism and others. In smears from ulcers and abscesses, fæces, &c., the amoeba coli, balantidium, ova of worms, &c., will be notified. By a blood examination also the condition of leucocythæmia, eosinophilia, and other changes will be made apparent.

4. *The Examination of Tumours and Diseased Tissues.*—In this respect there is an unlimited field for research. In practice in the tropics, conditions are constantly being encountered unlike anything seen at home. As a rule, these are dismissed after a rough diagnosis has placed them in some general group. By forward-

ing properly-preserved specimens, a great deal more might be learned regarding their real nature.

In transmitting tumours or pieces of tissue for examination only small pieces, never larger than a bean, should be placed in absolute alcohol for two hours and then transferred to 70 per cent. alcohol. In case absolute alcohol is not at hand, the pieces of tissue should be placed in rectified spirit. Specimens should be transmitted in weak alcohol, 70 per cent. In some cases it may be advisable to send the whole tumour. It should be forwarded in rectified spirit, freshly added before despatch, or in formalin 5 per cent.

5. *The Examination of Urinary Deposits, Fæces, Vomit, &c.*—All specimens of this kind should be sent with a crystal or two of thymol to prevent further changes. For the amoeba coli films should be made of the fæces immediately they are passed. Urine suspected of containing hæmoglobin can be sent for spectroscopic examination.

6. *The Identification of Mosquitoes, Especially of Anopheles.*—All biting flies are of extreme interest and they should be forwarded for identification. Even if the specific name cannot be at once given the genus in most cases can be notified to inquirers. All blood-sucking animals—ticks, fleas, lice—are of great interest, and if they are not identified by the Institute, steps will be taken to have all specimens forwarded to authorities at home.

Worms and specimens of fæces containing ova should be sent for identification. The possibility of new species of parasites should be constantly borne in mind.

*Tubercle.*—In the case of sputum, the morning expectoration should be made direct into a small, wide-mouthed bottle containing a little 1 in 20 carbolic and the bottle at once vigorously shaken. The bottle itself may be sent by post; or films may be made from the emulsion, and these only forwarded.

For tubercle bacilli in urine, the deposit should be mixed with a little 1 in 20 carbolic and forwarded without delay.

*Leprosy.*—Smears from open sores, or from scrapings of the leprosy lesions, will enable a diagnosis of leprosy to be at once confirmed. Pieces of tissue removed *post-mortem* should be sent for report. The splenic condition is interesting and smears from this and other viscera will be valued.

*Infective Granulomata.*—Smears from ulcers suspected of being due to yaws, syphilis, and possibly other undescribed causes should be sent for examination. Even if no result is obtained in many cases, there are sure to be instances where the diagnosis may have to be revised.

*The Gonococcus.*—Suspected discharge should be spread in as thin a film as possible upon a clean slide, by means of a needle as in making a blood film. Several slides should always be sent, as it is necessary to stain in several ways for diagnosis of the organism. Discharge from ophthalmia suspected of being due to the gonococcus may be similarly treated.

*The Pneumococcus.*—Films of sputum or smears from the lungs, meninges, &c., will, in cases of pneumococcus infection, often enable a certain diagnosis to be arrived at.

*Plague.*—The glands in plague, when swollen, contain the bacillus in large numbers. A little fluid should be drawn off by means of a hypodermic needle and a few smears made as described above.

In the pneumonic form sputa should be forwarded (film). Attention is also directed to the possibility of bacilli being present in the saliva in cases of submental glandular enlargement. In fatal cases films from the viscera and glands should be made. Splenic puncture in doubtful cases promises to be of great diagnostic value.

*Anthrax.*—In cases of suspected malignant pustule, a little fluid should be drawn by means of a hypodermic syringe from the tissues just beyond the slough. A smear should be made of this and the remainder placed in a sterile capillary tube for instant despatch. The tube should be carefully sealed.

The occurrence of pneumonic and intestinal anthrax should be borne in mind. Such cases, as well as cases simulating acute specific fevers or plague, may be readily overlooked.

*Diphtheria.*—Smears of the throat mucus should be forwarded. But for any definite answer to be given, a swab must be forwarded. Sterilised swabs in tubes for this and other similar purposes can be obtained from the Institute.

*Cholera.*—Films of some mucoid flakes should be forwarded. A carefully sealed capillary tube of the fæces should also be despatched at once.

*Dysentery.*—Films of dysenteric motions made immediately the motion is passed will, in cases of amœbic dysentery, show the amœba coli. Non-amœbic dysentery is to be suspected when such an examination is negative. A capillary tube of fæcal matter may be sent for the possible isolation of virulent organisms.

*Typhoid.*—Serum reaction as a diagnostic test for typhoid has met with a good deal of criticism. This has been largely due to a want of confidence between the bacteriologist and the clinician. In deciding upon the result of a serum test, several very important facts must be considered. Since a reaction is practically never obtained prior to the fourth or fifth day, and often not until the seventh, allowance must be made for negative results in the early stages of undoubted typhoid. Towards the third week the reaction becomes very intense, and, unless at this time the test acts in considerable dilution, grave doubt should be entertained as to its specific nature. In some cases it is difficult to say whether the reaction is of sufficient degree to raise it certainly above the possibility of normal serum action. If such a reaction occurred on the sixth day, it would be very suspicious of typhoid infection and a later development of a more intense reaction. If the same degree of reaction took place in the third week, it would mean little. In reporting upon blood sent for the purpose of the Widal test it will be necessary to fix a limit of dilution, which at the same time will detect the early onset of agglutinative action and will be removed from all possibility of normal serum action. This is pretty generally recognised to be a 1 in 30 dilution with most laboratory cultures of the typhoid bacillus. Specimens of blood for the Widal reaction should be taken in small pipettes which may be obtained from the Institute.

In cases of cystitis or abscesses suspected to be due to the *B. typhosus*, a capillary tube full of the fluid should be sent for bacteriological examination.

*Malta Fever.*—Undoubtedly the best way to detect Malta fever is to grow cultures from blood obtained from the spleen. Microscopical examination of such blood would in default of this be of value. As a matter of fact, no attempt has been made to do either of these in cases reported from India. Such cases have been diagnosed on the serum reaction. Unfortunately what we have said regarding typhoid serum reaction is still more the case when we come to deal with the *M. melitensis*. Owing to the fact that attenuation has in most cultures of *M. melitensis* greatly increased their susceptibility to normal serum action, the limit of specific reaction has to be raised to 1 in 100 or more. The neglect of this precaution has probably led to some mistakes in the diagnosis of Malta fever, and to a suspicion of the value of the serum test in general. There is, however, no reason why with greater precautions the serum test for Malta fever should not be of value.

*Malaria.*—Perhaps no test is of greater value in tropical medicine than the blood examination in an obscure case for the malaria parasite. In sending specimens of blood for this purpose as good a film as possible should be made. It is generally advisable to send several.

The slides used should be rubbed perfectly clean, after dipping in water, with a soft cloth, and protected at once from dust. Before taking specimens of blood the prepared slides may be placed in a small pocket slide box or merely wrapped in a clean sheet of note

paper. A packet of half a dozen prepared slides wrapped in a sheet of note paper, which is afterwards transfixed with a surgical needle, is a most convenient form of carrying the necessaries for taking specimens at the bedside. The needle should be an ordinary triangular pointed surgical needle. The last phalanx of the finger is taken between the finger and thumb of the left hand of the operator and gently pressed to force the blood towards the pulp of the finger. A slight prick with the needle causes a drop of blood to exude. When the drop reaches the size of the head of a pin, a slide is held in the right hand and lowered on to the drop. Care should be taken not to 'dab' the slide on the skin. If the drop is too large, wipe it away and squeeze a fresh one. The drop should be transferred to the slide about one-third of an inch from the end. The slide is then changed to the left hand, the finger and thumb grasping the end nearest to the drop. The right hand again takes the needle and holding it by the pointed end, lays the cylindrical shaft transversely to the slide and across the drop of blood. After waiting about a second—*i.e.*, until the blood spreads to the extent of one-third inch between the slide and the needle, the needle is evenly and not too quickly carried to the right and so along the whole length of the slide. The right amount of pressure is very easily learnt, and the making of a useful and good film is far easier in this way than in any other way known to us. Immediately the film is made it should be waved to and fro until dry in the air.

The slide when made should be carefully preserved from dust and wrapped at once in clean note paper. Notes can be written in ink on the back of the slide or by writing on the film itself with a needle.

To obtain blood from the spleen use an ordinary hypodermic needle. A large needle is unnecessary and liable to be followed by hæmorrhage. Splenic puncture should be done in all cases showing enlargement of the organ and a puncture of this organ would not be amiss in any obscure case of disease accompanied by rises of temperature. The following points should be observed in films sent for the detection of malaria: (1) it is not necessary to take the blood only when the temperature is high; (2) in sending films for a leucocyte count it is best to take the blood in an apyretic interval as, at this time, the increase in the large mononuclear leucocytes is greatest; (3) films should be thinly spread and should be forwarded at once without fixing.

*Filaria.*—Blood should be taken in the evening. The films should be made a good deal thicker than when detection of the malarial parasite is desired.

*Trypanosomes.*—Films as for malaria should be made. It is well to remember that trypanosomes are often found in œdema fluid when they are very scanty in the blood.

*Donovan Bodies.*—For forms in the spleen make films as in the case of malaria. To determine the presence of the bodies in ulcers snip off small pieces of granulation tissue with a sharp scissors and, after crushing, make a film, using the edge of a glass slide to spread the material.

*Relapsing Fever.*—Blood films should be taken at intervals, when the presence of the spirillum is suspected, as it at times disappears from the blood.

Examination of the peripheral blood for plague and other acute infective diseases is not of much use except possibly in the last stages. The examination of splenic blood is, however, of the greatest possible value not only in such diseases but in the study of infective diseases generally.

*Mosquitoes and Flies.*—These should be captured in tubes, specimen or test tubes, and killed with tobacco smoke. When dead they should, with as great care as possible, be turned out on to a clean sheet of paper. They should never be touched with fingers or forceps. They should be placed upon their dorsal surface and transfixed with a fine entomological pin No. 20, which has first been pushed through a piece of thin Bristol board. The specimen whenever possible should be mounted; if no fine pins are at hand it is better to place

the insects in a piece of glass tubing or between two sheets of tissue paper in a box.

Fleas, ticks, lice are best forwarded in spirit. All soft parasites should be given a plentiful supply of rectified spirit and labelled by placing a piece of paper in the tube with pencil writing upon it.

[ED. NOTE.—The third part of this interesting paper deals with veterinary diagnosis, and has been omitted here as it deals mainly with matters of interest to tropical readers.]

## The Out-Patient Departments.

### TOTTENHAM HOSPITAL.

*Dermatological Cases under the Care of G. NORMAN MEACHEN, M.D., M.R.C.P.*

CASE I.—*Accidental Vaccinia*.—A little boy, *æt.* 6, was brought by his mother with a "sore place" on his forehead, which had been there about six days. There was no history whatever of injury, but the mother stated that the child's baby brother of a few months old had been vaccinated a fortnight ago, and that they had been playing about together. On inspection, there was seen on the left temple a typical vaccinia pustule with a central scabby portion, and much local congestion in its immediate vicinity. The eyelids were swollen and oedematous, and the pre-auricular lymphatic gland was enlarged upon the same side. No other lesions were present. The boy had been vaccinated when an infant. From the clinical aspect alone, there should have been no difficulty in recognising the nature of this case, apart from any history that would lead one to suspect accidental vaccinia. This lesion was said to have begun as a "small pimple" which, in all probability, was really inoculated upon the site of an unnoticed abrasion of the skin upon the temple. The clearly defined circular shape of the pustule with the accompanying inflammatory reaction and the central part beginning to dry up would suffice to distinguish it from an impetigo or a furuncle. Enlargement of neighbouring lymphatic glands almost always occurs. The hands are, naturally the parts of the body more usually subject to accidental contamination with the vaccine virus, but typical lesions have been observed upon the female genitals, and upon the nasal mucous membrane. The interest of the present case lay in the fact that previous vaccination upon the usual site six years ago did not appear to have diminished the patient's susceptibility to a fresh inoculation. A simple lotion of boracic acid was ordered for external application.

CASE II.—*Bromidrosis of the Feet Associated with Eczema*.—The patient was a boy, *æt.* 14, an assistant in a public library, and, therefore, upon his feet the greater part of the day. His complaint was a painful soreness of the toes which rendered walking very difficult. He had been thus troubled for about three weeks. On examination, the skin of the toes of both feet was sodden, red, and weeping. The back of the heels were eczematous, and the soles were affected to a less extent with papules and minute pustules. The discharge had soaked through into his socks, and altogether he was in a pitiable plight. The left foot was much worse than the right. He stated that when he was well his feet always sweated a good deal. The hands were affected with a drier, squamous eczema. Otherwise he was in good health. There was also slight acne of the forehead. The boy said that he could not stay away from his work, so that the treatment was not quite so satisfactory as if he had rested the feet in the horizontal position. However, he was given a weak tar lotion for bathing the affected parts with, followed by dusting the toes well with an antiseptic, astringent powder composed of five grains of tartaric acid, ten of boric acid and equal parts of starch and zinc oxide to the ounce. An ointment of zinc and boric acid was also ordered for application to those parts which were more sore than the rest. Strict cleanliness as regards

foot-gear was enjoined at the same time. When seen a week afterwards the local conditions had much improved.

CASE III.—*Dermaographia of a Severe Type*.—The patient was a girl, *æt.* 18. She complained of intense irritation of the skin, which appeared to "come up in a rash" whenever she became heated. The affection had been present ever since she was a small child, and now the slightest friction with the clothes or rubbing of any kind would produce a wheal. She had had no previous illnesses. On examination, the skin appeared to be normal with the exception that there were several erythematous areas where the clothing had pressed. On passing a blunt-pointed pencil or the finger-tip lightly over the skin of the back, a vivid wheal was produced after an interval of ten to twenty seconds, which was speedily surrounded by a red halo. The sensation experienced was one of heat or slight burning. She was pale, but the cardio-vascular system was normal. The bowels were somewhat constipated.

Dr. Meachen remarked that urticaria factitia was one of the commonest manifestations of the so-called neuroses of the skin. This group of cutaneous disorders had been specially observed by Van Harlingen, Savill, and others, and the generally accepted view was that the vaso-motor system was at fault. Many varieties of erythema, morbid blushing, and the condition known as dermatographia, of which this patient was such a good example, were included under this category.

Acting upon the supposition that the intra-cutaneous capillaries were impaired in tone, five grains of the supra-renal extract were prescribed three times a day. Careful regulation of the bowels was also strictly enjoined. A simple anti-pruritic lotion of calamine was ordered for local application.

## British Health Resorts.

### VIII.—ST. IVES (CORNWALL).

[BY OUR SPECIAL MEDICAL COMMISSIONER.]

THE quaint little fishing town of St. Ives has long been beloved by artist and antiquary. Situated on the northern coast of the Cornish peninsula, it occupies a peculiarly picturesque position on an isthmus which separates a small promontory from the mainland, and looks eastward across the beautiful bay of St. Ives. The ancient town, with its narrow and roughly paved streets, solid, grey, irregularly placed houses, has much the aspect of an old-world Breton or Flemish town. St. Ives is a port and fishing centre of great antiquity. Even still, in spite of the modern builder's efforts and the tourist's invasion, old custom and long-established tradition rule and regulate the toil and delights of the simple, strong, peace-loving fishermen and hard-working and patient watching wives of the harvestmen of the sea.

St. Ives deserves to take high rank among our Western health resorts. It seems suited to the needs of many classes of visitors needing quiet, shelter, and yet pleasing occupation for the mind. We have stayed at St. Ives in the springtime and consider it a peculiarly suitable resort for this period of the year. Its position also ensures conditions which make it a pleasing summer station. And in the winter it can offer much that is particularly welcome to the invalid, for the climate is warm, equable and considerable sunshine is enjoyed.

Dr. J. M. Nicholls, the Medical Officer of Health, has kindly furnished us with copies of his reports for recent years. In 1901, the population of the St. Ives Urban Sanitary District, having an area of 1,100 acres, was 6,697, a density of population per acre of 6.69. The birth-rate in 1903 was 26.13 and the death-rate 14.18. The cancer mortality is returned at .59 per 1,000 of population and that from phthisis as .74 per 1,000. The water supply has been improved and progress is being made in sanitary reform. The mean temperature according to the report for 1903 was 52.22°, the highest

maximum being 71.3°, in July, and the lowest 29.5°, in January. The rainfall was 39.51 inches. The number of rainy days is returned as 209 and sunshiny days as 209.

The invalid visitor will not lack comfort and may even secure luxury in St. Ives.

The Tregenna Castle Hotel, admirably conducted by the Great Western Railway Company, is quite un-hotel like in appearance and well provides the comforts of a country mansion after a manner peculiarly welcome to the visitor seeking mental rest and bodily relaxation. From personal experience we can highly recommend this charmingly situated residence. St. Ives is not rich in hotels, but apartments can be found well suited to the requirements of the invalid. The immediate neighbourhood of St. Ives offers numerous advantages. Sandy bays of Porthminster and Carbis provide safe playgrounds for children. The golf links at Lelant have justly gained much distinction and attract enthusiasts from all parts of the country. The bay is ever at hand for boating and bathing; and the near highland supplies bracing opportunities for the pedestrian.

We consider St. Ives a particularly suitable resort for the artistic invalid needing a warm, light, sheltered and yet peaceful resort. It undoubtedly meets the requirements of many overworked professional men and is well suited to the special needs of sufferers from respiratory weakness. Convalescents from acute diseases and those recovering from prostrating affections may be expected to do well at St. Ives. Through the enterprise of the Great Western Railway, St. Ives, although 324 miles from Paddington, can be reached in a little over 7 hours; a through carriage can be taken to St. Erth Station on the main line, which is only 4½ miles distant from St. Ives.

## France.

[FROM OUR OWN CORRESPONDENT.]

PARIS, August 28th, 1904.

### TREATMENT OF COMA.

COMA is a state of somnolence characterised by the more or less complete loss of intelligence, sensibility, and mobility.

Apoplexy is not synonymous with coma; it precedes it, and is constituted by ictus or sudden loss of the cerebral functions. After a very short period, when this condition persists, coma follows. The treatment of coma varies with the affections which gave rise to it, says M. Fiessinger. It is met with in—

- (a) Affections of the brain and its membranes.
- (b) In certain nervous affections.
- (c) In certain intoxications.
- (d) In infectious maladies.

### DISEASES OF THE BRAIN AND ITS MEMBRANES.

*Traumatic lesions* of the cranium produce coma from compression by an osseous fragment or from hæmorrhage. Surgical treatment in such cases is clearly indicated. If the case is one of cerebral tumour, the patient will be placed on the specific treatment in the hope that the neoplasm may be of syphilitic nature. In case of failure surgical treatment, consisting in trephining and the extirpation of the tumour, especially if a limited paralysis indicates the exact place of the operation, will be adopted. Before, however, having recourse to this operation, lumbar puncture might be tried, which is an excellent palliative for vomiting and headache; it can also act on the coma when it is due to an excess of cerebral tension, as might occur in cases of tumour. Care should be taken not to remove more than two or three drachms of the liquid. The evacuation may be renewed every two days.

*Coma with contractions* in a child or in an habitual drinker indicates hæmorrhage of the membranes. The treatment is that of ordinary encephalic affections:

local or general blood letting, ice to head, calomel, mustard to the extremities. Almost the same treatment is used for *cerebral hæmorrhage* and softening of the brain. The coma in these two affections is difficult to differentiate one from the other.

*Embolus* produces rapid coma without vertigo or premonitory symptoms. The co-existence of a cardiac or aortic lesion will clear up the diagnosis. Diffusible stimulants, injections of ether, camphorated oil dry frictions, sinapisms, should comprise the treatment.

*Thrombosis of the sinus*, sometimes preceded by hemiplegia, monoplegia, Jacksonian epilepsy, may provoke rapid and complete coma. Thrombosis may be suspected in a patient cachectic from dysentery, cancer, chlorosis, tuberculosis, or who has suffered from otorrhœa. Here treatment is powerless.

Sometimes *acute mania* terminates by delirium followed by coma. As it is a case of encephalitis with congestion, lumbar puncture may be tried. Abscess of the brain frequently follows tuberculous osteitis of the petrous portion and is usually terminated by coma. It is for the practitioner to judge if the patient can support an operation. The coma of *general paralysis* succeeds to apoplectiform seizures. It is generally of short duration. The mercurial treatment appears to give some good results. For a long time M. Huchard places a seton at the back of the neck as a prophylactic treatment of the complications of general paralysis as well as in the majority of comatose accidents in other cerebral affections. The seton is left in place from three to six months; it is not very cleanly, but efficacious.

*Insolation* is accompanied by coma. Application of ice to the head, blood letting (12 ounces) and a drastic purgative is the treatment habitually employed.

### NERVOUS AFFECTIONS.

*Epilepsy* is a frequent cause of coma. It forms a part of the attack and follows the convulsive stage. Active treatment is not necessary: the epilepsy should be treated and not the coma, which is rather favourable to the patient by furnishing to the organism the means to recuperate the energy spent on the paroxysm.

*Hysteria* is accompanied by sleep rather than coma. The limbs are slightly contracted, maintaining sometimes the cataleptic attitude given to them. Children are sometimes seized with coma from a reflex cause. Worms may be suspected in such cases and treated accordingly.

*Intoxications*.—Besides the coma produced by such poisons as opium, belladonna, carbonic oxide, and alcohol, there exist others produced by certain maladies—as diabetes, uræmia, dyspepsia, and cancer. The *coma of diabetes* is observed in the gravest forms of the malady. Sometimes, and especially in children, coma is the first sign of diabetes. A good deal has been written on this complication. The alkaline treatment—one to three ounces of bicarbonate of soda in the 24 hours—has been recommended, but without much result. Preventive treatment is the surest—absolute suppression of meat, large doses of bicarbonate of soda, drastic purgatives. The treatment of *uræmic* coma is that of coma from œdema of the brain, as observed in Bright's disease.

### INFECTIOUS DISEASES.

Two kinds of coma are observed in infectious maladies—*coma vigil* (typhoid fever) and *profound coma* with immobility and complete insensibility of the patient (eruptive fevers, paludism, acute articular rheumatism). The treatment varies with the nature of the causal affection, but generally speaking, warm baths (pneumonia, cholera), cold baths (typhoid fever), subcutaneous injections of caffeine, ether or camphorated

oil prove sufficient. At the same time the patient will absorb cooling drinks in abundance, and if he is strong enough to bear it, from six to eight ounces of blood may be taken from the arm.

### Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, August 27th, 1904.

At the meeting in Prague, Lielebaen reported on a few cases of œsophagotomy, which he had performed on patients for obstruction in the œsophagus, that were quite out of proportion to the size of the foreign bodies impacted.

The first was a child, æt. 1½, who had swallowed a button 23 millimetres in diameter. It was observed by the œsophagoscope, but all ordinary efforts failed to lift it. Surgical bleeding commenced that led to immediate operation. When the gullet was opened, the wall of the tube was found quite gangrenous and thin, which led to a fatal termination within twelve hours after the operation, owing to an acute attack of lobular pneumonia.

The second was a child, æt. 5, who swallowed a piece of pipe stem 25 millimetres in diameter. Every effort to remove it by probing, &c., failed, although it was only 14 centimetres beyond the back teeth. The speaker saw the case a week after the accident, but he failed to remove the obstruction, although discernible with the œsophagoscope. He operated and left the opening without a stitch for twelve days, through which he passed a tube. The wound finally healed, and the patient recovered.

He related a third—a servant, æt. 17, who swallowed a small bone while eating duck. She was unable to swallow fluids, had great pain, and right-sided torticollis. The operation revealed part of a duck's cervical vertebra impacted in the wall. The patient rapidly recovered.

#### KERATOCONUS.

Bosser exhibited a female, æt. 21, who had suffered from the malady for two and a half years. The treatment consisted in cauterising the membrana Descemeti till perforation was produced, which was accomplished after the third application. Before the operation she was only able to discern fingers one metre distant, now she was able to do so at ½.

He also showed an interesting condyloma scleræ, which might easily be mistaken for a gumma. The man was æt. 25, but had no sign of secondaries such as papules in mouth, &c.

#### HEMIANOPSIA IN URÆMIA.

Pick gave a long and exhaustive history of a case of hemianopsia coming under his care. The patient was a tripara in her ninth month of pregnancy, with all the symptoms of uræmia and eclampsia. Labour was prematurely induced, which improved the uræmic symptoms, but this was followed suddenly by amaurosis that prevented the patient distinguishing between light and darkness. After a time this improved and two weeks after she was so much better that she left the hospital, but after a short time at home she felt her right arm had grown quite weak, which induced her to seek medical advice.

On examination, she was found suffering from chronic nephritis, hypertrophic cardia, hemiparesis dextra, and distinct right-sided hemianopsia, with slight retinitis and albuminuria.

The paralysis soon improved but the hemianopsia continued. Pick recollected another similar case he attended in 1897 which died. The post-mortem revealed

a soft circumscribed centre in the second occipital convolution, which presumably had its origin in an embolus. In many cases, however, of uræmia the amaurosis is observed to be very transitory, passing off in one or two days and not exceeding a week. He considered the case he had shown was one of a toxic origin which had produced the cerebral lesion.

In the discussion that followed, Luksch and others considered the real cause of the amaurosis to be due to emboli rather than toxin, or a toxin lesion of the cerebral substance.

#### ANTHELMINTICS IN CHILDREN.

Ritter drew attention to the difficulties and dangers of using *Filix mas*, which he had used for the last four years in the Franz Josef's. He considers the *Floreo kusso* to be much better, although it was not a trustworthy drug in its results. In twenty-eight cases he had used the *Filix mas* and only succeeded in six cases to securing the scolex.

The "junq clause" preparation of *semina cucurbitæ* was a much more efficacious drug for tænia. This is an extract of the seed having a dark, thick consistence and an agreeable taste. One dose represents 300 seeds. In eleven cases he had only three failures to obtain the scolex. Its great advantage lay in its agreeable taste, efficacy, and freedom from any danger to the patient. After a very short interval the appetite is good, and it may be repeated without any danger.

The mode of prescribing it should be observed. The night before, a dose of opening medicine or an enema should be given to clear the bowel, after which a little soup or coffee should be given as supper. In the morning the "junq clause" may be given, followed in two hours by castor oil or other aperient.

### Hungary.

[FROM OUR OWN CORRESPONDENT.]

BUDAPEST, August 27th, 1904.

#### HYPEREMESIS GRAVIDARUM.

DR. ODÓN (TUSZKAI, Professor of Gynæcology, Budapest, whose contribution on hyperemesis gravidarum appeared in these columns about a year ago, now concludes his investigations in the following summary:—

I.—Hyperemesis produced solely by gravidity is one of the rarest complications of pregnancy.

II.—We have strictly to distinguish between vomitus gravidarum occurring during gestation, and between hyperemesis gravidarum specifica. Also we have carefully to discern by exclusion those diseases which cause vomiting in pregnant women, too; thus: gastric troubles, meningitis, peritonitis, hydrops, &c.

III.—The diagnosis of hyperemesis gravidarum can be made with certainty under the following conditions: (a) If we were able certainly to exclude the diseases mentioned under II., *viz.*, with the adoption of all the diagnostic and therapeutic methods and means. (b) If after these we find all the characteristic clinical symptoms, *viz.*, great local tenderness of the peritoneum and of the uterus, which tenderness not only increases on bimanual examination, but also gives rise to vomitings or violent retching and nausea. (c) If the frequent and severe vomitings occur also without taking food, and show within a short period the symptoms of inanition.

1. The quick decrease of the body weight, the daily quantity of urine, its chlorides and the red blood corpuscles of the blood.

2. The increase of the quantity of urine, its specific gravity, also the alkalinity of the blood, and the pulse-rate.

3. The appearance of albumin and kidney elements in the urine, and the presence of normoblasts and uninuclear megaloblasts in the blood.

4. The sudden fall of the morning temperature, and in opposition to this, the febrile or subfebrile rise of the same.

IV.—The symptoms of hyperemesis gravidarum were explained from the irritation of the perimetrium, which most probably originates on account of its individual and occasional properties from a local atrophy, and thus it is in causal nexus with gravidity.

V.—Prognosis is evidenced from the degree of inanition, in relation to the bodily condition of the individual. Evidence is gained by the above-described biochemical reactions.

VI.—On these grounds we shall be in the position to employ causal treatment, which in the forefront is conservative (local cold, heat, complete rest, large doses of opium), and only in cases of entire failure do we interrupt pregnancy, when the life of the mother is endangered. This operation can be performed very easily and comfortably by the method described above.

## The Operating Theatres.

### ROYAL FREE HOSPITAL.

GASTROSTOMY.—Mr. T. P. LEGG operated on a man, *æt.* 46, who had suffered from difficulty in swallowing solid food for nine months, and during the last three months had been getting very much thinner. For the past week the patient had been unable to take either solid or liquid food. He had also had a good deal of pain in the mid-dorsal region. On admission he was considerably emaciated and at once regurgitated any liquid which he attempted to swallow. There were several enlarged firm glands in the supra-clavicular spaces on both sides of the neck. He had no cough. A full-sized œsophageal bougie could not be passed further than nine and a half inches. A small bougie (No. 12) passed seventeen and a half inches, but was tightly gripped about nine inches from the teeth. A No. 15 bougie was stopped nine and a half inches from the teeth. The diagnosis was obviously one of carcinoma of the œsophagus, and a modified Franck's method of gastrostomy was performed. A vertical incision two and a half inches long was made just to the left of the middle line; the rectus sheath was opened and the fibres of the muscle separated; the peritoneal cavity was opened in the same line and the stomach at once brought into view, and a cone-shaped portion brought out of the wound. To the apex of the cone a couple of silk sutures were fixed. A second incision one inch long and parallel to and an inch and a half to the left of the previous incision was then made; this incision opened the sheath of the rectus near the outer margin of the muscle, the fibres of which were split into an anterior and a posterior layer by passing a blunt dissector from the second to the first incision through the substance of the muscle. A pair of forceps was next passed through the gap in the muscle thus made, and the guide sutures, which had previously been fixed to the stomach, were seized and drawn through. The cone of the stomach wall was then made to occupy the space between the layers of the rectus muscle, the apex being drawn through as far as the second incision, to which it was fixed by four sutures passed through the serous and muscular coats of the stomach and the skin and rectus sheath. The base of the cone lay in the

first incision and was fixed to its right margin by three or four stitches which united the fibres of the rectus, the posterior layer of the sheath and the peritoneum to the sero-muscular layer of the stomach. The apex of the cone was incised and the mucous membrane fixed by a couple of sutures to the muscular coat. A No. 10 catheter was passed into the opening thus made and to prevent it slipping in or out, a silkworm-gut suture was passed through it and the skin a short distance away from the opening in the stomach. Four ounces of peptonised milk were passed through the catheter into the stomach before the patient was taken back to bed. Mr. Legg said there were two chief methods of doing gastrostomy, and the one adopted here was only possible when the stomach was sufficiently large to allow a cone-shaped piece to be easily drawn out of the wound; this was not always the case, and under these conditions an operation known as Witzel's had to be done. The operation of gastrostomy, as had just been performed, was, he thought, most satisfactory, for even on coughing there was practically no escape of the gastric juice and contents of the stomach, which had such an irritating effect on the skin, the cone of stomach being entirely surrounded by muscle fibres, which act as an efficient sphincter. Mr. Legg thought it best to open the stomach at once and to give the patient food at the completion of the operation; there was no risk of the contents of the stomach infecting the peritoneum, and the patient does not vomit as a rule. Another reason for opening the stomach at once, he pointed out, was that the patient not infrequently had been unable to take sufficient nourishment by mouth for some time previous to the operation. At best, he remarked, gastrostomy can only be considered as a palliative measure; the patient frequently puts on flesh, recovers some degree of strength, and is able to swallow naturally, at least for a time. Whether life is prolonged or not to any appreciable extent was, he considered, doubtful, but the rest of the patient's existence was rendered far more comfortable and bearable. The method of feeding of patients after the operation was, he considered, very important. His usual plan, he said, was to give four ounces of peptonised milk with half an ounce of brandy every four hours, increasing the quantity to six, eight and ten ounces from time to time and diminishing the amount of peptonisation. If he can swallow it was a great comfort to the patient to supplement the artificial feeding by natural means; one often finds that the patient is able to take bread and milk, milk pudding and mince-meat when previous to the operation he had been quite unable to swallow. The only objection, however, to this being allowed was the irritation of the growth in the œsophagus.

A week after the operation was performed the patient was getting up and after a fortnight was going out daily into the hospital square, feeling much stronger and putting on flesh, while no longer looking so emaciated.

### Medical Communism.

AN interesting medical innovation has just been made by the town of Zurich. It has created a medical tax of 3s. 7½d. per head of the population with a view to raising £20,000. Forty doctors in the town will share this money, each receiving an annual sum of £500. In return for this salary they will be expected to give their services to "all" the inhabitants of Zurich.—*Advertiser.*

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, AUGUST 31, 1904.

**MEDICAL MEN AND ADMINISTRATIVE JUSTICE.**

No section of the community comes habitually into closer contact with the inner life of the nation than the medical profession. Their duties carry practitioners of medicine into the homes of all classes as well as into workhouses, hospitals, schools, prisons, and reformatories. In this way they become acquainted with the histories of a vast number of persons, who, in many instances, confide their private affairs as a matter of course to the ear of their medical attendants. They are therefore in a position to know as much as most people how administrative justice deals with accused persons in all parts of the United Kingdom. As a rule, the average Briton who comes across a miscarriage of justice shrugs his shoulders and says nothing more about it. From a prolonged experience of police administration he knows that little satisfaction on the one hand and a vast amount of trouble and annoyance on the other are likely to result from any personal intervention of his own in any matter of individual injustice. In New York, where Tammany rules the roost, citizens live under a reign of police terror, in which blackmail, intimidation, organised conspiracy and legalised violence appear to be the recognised weapons. Here in the United Kingdom, police administration, although marred by many gross defects, is, on the whole, perhaps the best system of civilian peace administration in the world. The system, however, has not kept pace with the times, and of late years there have been many signs that the patience of the public has become strained to the last point of endurance, and that reforms will have to be prompt and thorough in all branches of the criminal executive. The savage sentences of many years of penal servitude constantly passed upon prisoners for trifling offences against property in themselves constitute

a standing blot upon our criminal code. The additional punishment of a man for offences purged by previous penalties is another gross injustice. The whole system of criminal administration and procedure, in short, requires vigorous overhauling and reconstruction in the light of modern humanity and social justice. The shock to the public confidence caused by the revelations of the Beck case must be followed by a reaction of indignation and clamour that will place the British courts of criminal justice absolutely above suspicion. Until recently the vast majority of our countrymen would have scoffed at the idea of anyone being sentenced to two terms of penal servitude and being oppressed by the police for offences committed by another man. The inwardness of the police attitude in continuing the second prosecution with the full knowledge that the identity of the accused in the first trial had been mistaken demands searching inquiry. That there have been many more kindred instances of miscarriage of justice who can doubt? Dr. Bell Taylor, of Nottingham, a gentleman whose testimony may be regarded as absolutely unbiassed and responsible, comes forward with no less than three instances in which his own personal interposition has procured the release of persons from gaol for offences they had never committed. In the first instance, when attending to give evidence he went by accident into the wrong court and heard enough of what was going on to interest him in the case. On medico-legal grounds he came to the conclusion that the accused, who was sentenced to eight years' penal servitude, was innocent, and he ultimately secured the release of the prisoner by the authorities. In the second instance he was taken by chance to the wrong cell in a convict prison, when making a professional visit, and heard enough to convince him the prisoner was being punished for murdering a wife whose death was due to disease. That convict was also released. In the third instance he was struck by the inconsistency of evidence in the account of a criminal trial read casually in a newspaper left on his table. Once more his intervention secured the release of an innocent man. These cases, it must be remembered, were not sought for; they came by chance into the path of a busy medical man. The reflection naturally arises that many more such cases must have come within the knowledge of members of the medical profession. If so, it is surely their duty to speak out, especially now that the time is ripe for setting straight the crooked ways of criminal administration. The first great reform wanted is a court of criminal appeal, of such a kind that every kind of sentence, however trifling, should be subjected to an automatic revision.

**DIET IN RELATION TO DENTAL DISEASES.**

We have in these columns often urged the importance of taking serious note of the wholesale decay of the teeth of the nation. The subject is accorded but scant attention by many to whom

the physical degeneration of the race is a source of anxiety; yet it seems probable that not only are the two questions intimately blended, but that the teeth give the direct clue to much of the ill-health and stunted development of citizens of to-day. The condition of the mouths of the present and of the rising generations is described by some authorities as simply appalling; the abysmal depths of degeneration—we might even say devastation—that the teeth of the British nation has reached is unrealised by those who have its welfare at heart. In giving evidence before the Royal Commission on Physical Training, Dr. Leslie Mackenzie stated that out of six hundred Edinburgh school children examined, five hundred and twenty-one had decayed teeth of the first set, and a hundred and ten of the second set; whilst Professor Hay, in Aberdeen, found that of a similar number of children three hundred and eighty-one had decayed teeth of the first, and three hundred and eighty-eight of the second set. The British Dental Association examined ten thousand Poor-law children, and discovered dental caries in no less than 86 per cent. of them. It may safely be said, then, that the number of persons who reach the age of twenty without decayed teeth must be so small as to be practically negligible. Surely no one can deny that we are here faced with a fact of the gravest moment. This universal destruction of the teeth can be accounted for only by the operation of some universal cause, and that cause should be diligently and persistently sought out and removed. The mouth is the very gateway of the body, and with it in a constant condition of unhealthiness, one must indeed be optimistic or blind to expect sound physique and hearty vigour in the possessor. A thoughtful paper was read by Dr. Sim Wallace at the recent annual meeting of the British Dental Association at Aberdeen on the connection between physical degeneration and dental caries, in which an original line of reasoning was followed with the object of showing that it is to the food of the people that their dental troubles must be attributed. Without committing ourselves to Dr. Sim Wallace's conclusions, we may say that his paper was suggestive, and deserves to be well pondered. He began by pointing out that there is no evidence that the ill-developed classes of society have teeth more susceptible to decay than those of good physical development, but that admittedly conditions of malnutrition and emaciation act prejudicially to the proper growth of the teeth. So long as the teeth are defective it is hopeless to expect physical development to go on satisfactorily. The two developments are intimately correlated. He then dealt with the evils resulting from infected cavities in the teeth and from vitiation of the oral secretions by the products of bacterial action, and showed that much as these undoubtedly lowered the resistance of the mouth and throat to disease onslaughts, an even more serious result is the chronic absorption into the blood of septic matter. In these ways

the lower classes, even though they set out better equipped dentally than their superiors, suffer greater impairment of health, for they are far less careful of their mouths than their more fortunately circumstanced fellows. But the most interesting part of Dr. Wallace's paper was that which discussed the cause of the modern inferiority of teeth to those of our forebears. Dr. Wallace had often been struck by the superior quality of the teeth of those who ate the least soft and refined food, and by the fact that such people possessed better digestions than those brought up on refined and apparently physiologically digestible food. It is his deliberate opinion that food demanding thorough mastication in the mouth is not only best for the teeth but for the stomach and intestines also, and that the early decay of teeth and the sluggish action of the alimentary canal, which is evidenced by indigestion and constipation, are the direct outcome of the habit of eating refined, soft food. Such foods allow the function of mastication to fall into desuetude, and the child, when he finds a lump in his food, falls into the habit of swallowing it whole; the teeth decay and the digestive functions become perverted. All these circumstances lead to a demand for still softer and more nutritious foods and the evils are perpetuated in geometrical progression. Dr. Sim Wallace is prepared to attribute to this unnatural tendency not only dental caries, but also diseases such as appendicitis, rickets, neurasthenia, adenoids, and anæmia. We are inclined to agree with him that the preparation and quality of food used at the present day are some of those circumstances of civilisation that operate differently to what might have been expected. It is a well-known fact that the physiologically perfect products of the laboratory combined in theoretically perfect quantities frequently fail to nourish those to whom they are administered, whilst natural foods that contain much that appears unnecessary and harmful, agree well. No one can regard with pleasure the consumption, now so fashionable, of artificial, concentrated food products, and it is quite possible that the indigestible parts of natural food may have a useful function to perform in the economy. One of these functions may certainly be that of keeping the teeth in healthy order, and, if this be so, while the present dietetic arrangements in the community persist, it is not likely that any amelioration in the teeth of the race will take place. Evidence telling in favour of Dr. Sim Wallace's theory should be eagerly sought, for there must be a good deal capable of being brought forward if it be the true one. At any rate, the whole subject is one of so much moment that no efforts to ascertain the facts should be neglected. Dental caries has been lightly regarded far too long; it is now assuming dimensions that are more or less alarming.

#### THE PRIME MINISTER ON MATTER.

It is, perhaps, useful that the opening address to a conference of men of science should be given

by one who is not himself a man of science. The priesthood of science is, like other ecclesiastical orders, inclined to be somewhat narrow, and to arrogate to itself a dogmatism which is in essence quite unscientific. Absorbed in some particular branch of study, and necessarily heedless of much outside that branch, a man of science is almost bound to lose to some extent his sense of proportion, and this all the more, the more he is absorbed in his work. It always helps to restore, at any rate to some extent, this sense of proportion to hear problems of science discussed by a sympathetic and intelligent outside observer. This is, we think, Mr. Balfour's position as regards science, and we doubt not but that some such considerations as these were in the minds of the members of the British Association when they invited him to become their President. It has been said of the Prime Minister that he cannot discuss any subject without bringing in metaphysical considerations, so that it is hardly to be wondered at that, carefully as he attempted to guard himself, his "Reflections Suggested by the New Theory of Matter," sometimes transcended the limits of physical science. Indeed, it would be hard for any discussion on the nature of matter to be anything else than transcendental, since matter is the *datum* of physical science. Just as mathematics cannot proceed unless certain fundamental principles, to wit, the axioms, are assumed, so, without the assumption of matter as its ultimate principle, is physics non-existent. Mr. Balfour, however, seems to forget that any physical theory of matter, however far back it may explain what we see and feel, leaves matter still there. He seems to give an undue weight to modern discoveries, which have altered our conception of matter by showing that the atoms, which we formerly regarded as ultimate, are themselves composite. "There are those . . . who think that the elementary atom of the chemist, itself beyond the limits of direct perception, is but a connected system of monads or sub-atoms, which are not electrified matter, but are electricity itself." What then? We have merely carried the analysis a little further back and we deal with "monads or sub-atoms," instead of atoms. But how does it help us to call them "not electrified matter, but electricity itself"? We can have no conception of electricity apart from its action on atoms, or monads, or whatever other name we care to give to the units of matter. And by no juggle of words can we do away with this supposition of matter. But like Mr. Balfour we fear we are becoming metaphysical. In the concluding part of his address Mr. Balfour gives an interesting explanation, based on the principle of natural selection, of the inevitableness of our shortcomings in the field of knowledge. "So far as natural science can tell us, every quality of sense or intellect which does not help us to fight, eat, and to bring up children is but a by-product of the qualities which do. Our organs

of sense-perception were not given us for purposes of research, nor was it to aid us in writing out the heavens or dividing the atom that our powers of calculation and analysis were evolved from the rudimentary instincts of the animal." As this is true of our perceptive faculties, so much more is it true of our speculative powers, and the fact goes far to explain to us the limits of our powers. Rightly understood, however, a knowledge of our limits should not be an incentive to pessimism, since it helps to guide us to a useful activity. At the same time it teaches science and philosophy alike that they have limits which they cannot transgress. "There are more things in heaven and earth than are dreamt of in your philosophy" seems to be the lesson Mr. Balfour wished to impress on the members of the British Association, and through them on students of science generally.

### Notes on Current Topics.

#### Scarlet Fever and Hospital Isolation.

IN the present issue of THE MEDICAL PRESS AND CIRCULAR we publish two important articles dealing with the hospital treatment of scarlet fever. For some years past the belief has existed that the system of hospital isolation has not proved a success so far as the diminution of incidence or of case-mortality has been concerned. The writer of one of the articles mentioned, Dr. Killick Millard, has been one of the earliest and most persistent critics of isolation hospitals in regard to scarlet fever. One of his chief contentions appears to be that the isolation hospital fails to isolate. Our second writer, Dr. H. Biss, contributes a full and scholarly article, of which the first part deals mainly with the impossibility of diagnosis of anomalous cases of that specific infection, where the characteristics of rash, sore throat, temperature, may be altered beyond recognition or altogether absent. Under such circumstances it is clear that it would be impossible to devise an absolute system for the notification of all cases of the malady. It follows that any form of isolation would be impossible, because many cases would escape identification. The superiority or otherwise of hospital over home treatment of the disease forms another branch of the discussion. Readers of these excellent articles will doubtless bear in mind that the majority of public health authorities maintain that the hospitals furnish the only possible solution to the problem of how to deal with scarlet fever.

#### A Bacteriological Institute in Madras.

THE subject of tropical medicine offers a wide and, to a great extent, unexplored territory to the scientific investigator. The enormous social and economic importance of this special branch of knowledge can only be dimly realised. Hitherto it has been customary to reproach the medical profession in tropical countries with the laxity and the conservatism of their scientific methods.

The brilliant discoveries of recent years, however, have done much to wipe away that reproach. At the same time it may be generally asserted that the level of scientific public health administration in our tropical colonies is still in a backward state. In India, for instance, in army as well as in civilian life, the facilities for bacteriological research were non-existent, and the only work done in that direction was that of a small knot of scientific enthusiasts. Nowadays all that is changed. The keynote of present medical administration in India is the predominant necessity of the bacteriological and the chemical laboratory. One of the most recent additions to the strength of the advanced scientific army in India is the King Institute in Madras. By the energy and persistency of Lieut.-Colonel W. G. King, C.I.E., I.M.S., a fully-equipped Government laboratory has been established in Madras. The departure is full of interest, as it furnishes an example not only to all British colonies and dependencies, but one that may suggest serious reflections to sanitary administrators in the United Kingdom. An account of the King Laboratory work will be found, by Colonel Christophers, among the Original Communications.

#### Another Drink Cure.

It is a thousand pities that ministers of religion, in common with many other well-meaning people, take so little trouble to enlist the sympathies of the medical profession in many of their philanthropic schemes. They cannot be unaware of the enormous amount of charitable work cheerfully performed year in and year out by medical men, and if they would take the trouble to inquire into the subject they could easily find out why the medical profession preserves the code of ethics laid down by Hippocrates. That code is the guarantee to the citizen that in consulting a medical man his highest and best interests will be scrupulously respected. Yet ever and again we find clergymen deliberately flouting all that the medical profession hold dear, and, from mistaken motives of philanthropy, running counter to those traditions that should be regarded as inviolate. The vicar of St. Luke's, Camberwell, the Rev. Hugh B. Chapman, has been stirred by the wonders of some drink "cure" to start a campaign to exploit this remedy on his own account. We have no knowledge of Mr. Chapman. However willing we may be to believe in the personal disinterestedness of his action, we cannot condemn in too strong terms the form that his appeal has taken. Two months ago he wrote to the press, saying "that he had come across a striking remedy for dipsomania, and since then he has had 1,800 letters of inquiry on the subject." With the rashness of a tyro he has himself undertaken the treatment of eleven most distressing cases, need we say, with complete success? So great is his confidence in the "remedy" that he has now written to the lay papers again, asking that all applicants for relief from alcoholic habits should communicate with him, and that he will be pre-

pared to undertake their treatment. The generous proprietor of the "cure"—"a purely vegetable drug, guaranteed perfectly harmless"—has placed a supply at Mr. Chapman's disposal for a nominal sum, seeing, no doubt, a splendid advertisement for his goods by so doing. Mr. Chapman admits that his object is to bring this remedy within the reach of all and secure it for the common good. Has he, we wonder, acquainted himself with the life-history of a hundred and one of these "drink cures" that have had their little day, and disappeared when their credit was gone and their owners sufficiently enriched at the hands of their victims? Mr. Chapman should know that the medical profession refuses to prescribe esoteric drugs that are exploited as private ventures, because it considers such a proceeding detrimental to the interests of its patients, and because secret remedies, like secret societies and secret dealings of all kinds, are contrary to public policy.

#### A Strange Congress.

MAN is a gregarious animal. Whenever opportunity offers or excuse admits, he foregathers with those of his fellows to whom he is bound by some tie, real or imaginary. Every species of humanity has its club, its congress, its annual dinner. Sometimes such gatherings are organised on the plea of mutual edification; at other times frankly on that of good-fellowship. But the general result is usually a "good time." A curious *réunion* in Paris was that lately called into existence to promote the interests of, and cultivate friendly feelings among, fat men, the qualification for entry being the possession of so many stones of bodily weight. Surely, however, a stronger aggregation never took place than that recently held at Coney Island to welcome "graduates" reared by infant incubators. To this congress repaired no less than fifty infants and young children who owed their presence on earth to the invention of Dr. County, including in their ranks the famous Cohen triplets, now in the blush of their third summer. These latter infants were born in a tenement house in New York, and together weighed at birth as much as one healthy child, but after a process of incubation at the Pan-American Exhibition at Buffalo, they all managed to attain presentable proportions. Dr. Wallace Lee, who first installed the system of incubation at the Omaha Exposition in 1897, told the assembled crowds that whereas 97 per cent. of the class of infants now successfully reared by the incubators used to perish before their introduction, up to the present he had only lost thirteen out of a hundred and twenty-six. In this year's infant colony at Coney Island there are no less than three sets of twins and one of triplets, all flourishing. The proceedings of the Congress were apparently marked by great cordiality, but in the report of the meetings it is not mentioned that any of the "graduates" related the experiences of his early up-bringing. Perhaps they are being reserved for some imaginative novelist. At

any rate, the time passed pleasantly, and if the *menu* of the annual dinner was a simple one, it was probably better suited to the digestive organs of the guests than the elaborate concoctions of French *chefs* usually are.

#### Neurosis of the Œsophagus.

THE functional diseases affecting the Œsophagus have not received much attention from clinical observers, probably on account of their comparative insignificance. Nevertheless, many distressing morbid conditions may result from neuroses of this portion of the alimentary canal. The so-called "globus hystericus" is, perhaps, the most familiar of all functional disturbances of the Œsophagus, and one which is specially associated with hysteria. The sensation of something slowly rising in the throat which threatens to choke the patient is a symptom at once seized upon by the physician as proof positive of the existence of functional nervous disorder, and valerian and assafoetida are forthwith prescribed. Knott, in his classic monograph upon the subject, states that the phenomenon of globus is directly produced by spasmodic contraction of the muscular fibres of the gullet, though he does not specify which layer. Dr. A. L. Benedict has found that spasm of the Œsophagus may be induced physically, as, for instance, by attempts at swallowing when the throat is dry, or by cutting short a fit of laughter by sudden deglutition. In states of passion or great emotion the functions of the Œsophagus are often much perverted, swallowing being sometimes absolutely impossible under such circumstances. Cases of spasmodic, intermittent dysphagia have been described by Graves, Paget, Brinton, and others, in which there was not the slightest evidence of any hysterical condition, but the subjects were neurotic. The recognition of such cases is a matter of no small difficulty as they sometimes occur in elderly patients in whom the suspicion of malignant disease may be entertained. The cautious exploration by means of the Œsophageal sound will determine the presence or otherwise of obstruction, and in functional cases the mere passage of the instrument may have a curative effect.

#### The Wisdom of Swimming.

WE teach in our public schools much that is useless for the true development of the mind and, it may be, in many cases, actually damaging to the body. Our sins of commission are great, but our errors of omission are greater. At this season of the year the desirability of making swimming a compulsory part of school training is occasionally discussed, but the fact remains that a vast number of our school children are altogether devoid of any knowledge of the art of swimming. It is true that many excellent public baths are springing up in cities and urban districts, but the greater number of the smart towns and villages of our country offer no facilities for swimming, and even opportunities for bathing for cleansing purposes are scanty. We contend that

in the interests of the physical development of our people, and as a wise, prophylactic measure for the safeguarding of valuable human lives, swimming should be made a compulsory element in every public school education.

#### Life Losses on the Alps.

THE Alps have been well called "the playground of Europe," but for many a life rich in distinction and promise for humanity they have proved the graveyard. This year the number of mountaineering disasters has been exceptionally large. Some of the accidents are such as may be considered inseparable from the risks of high sport, but many others are the outcome of recklessness. The neglect of elementary principles of hygiene, the excessive exertion of untrained bodies, the absolute lack of mountaineering knowledge, lose many a valued life. And warning is needed by all sorts and conditions of men and women. We write from personal knowledge of the ways of the average Englishman and Englishwoman when the keen glacier air has whetted the natural appetite for feats of strength and endurance. Many a teacher and many a student seek recreation among the mountains without a thought or care for their own fitness for the exercise proposed. Ropes are tested and axes examined, but the climber rarely thinks it necessary to wait for a physical examination into his own powers of endurance or ability to meet the stress and strain of prolonged exertion. It is useless to agitate for a study of hygiene in our schools if the teachers neglect the first steps to secure a rational method both of work and of play. The heavy death roll of the mountains during the past few weeks is sufficient argument for our contention that a thorough medical examination should be made of everyone who intends to woo the delights and dangers of prolonged exertion among the beautiful evil Alps.

#### The Treatment of the Summer Diarrhoea of Infants.

THAT veritable scourge among the infantile population, summer diarrhoea, has once more appeared in our midst coincidentally with the fall of the atmospheric temperature. In many localities, it is already alarmingly prevalent, while in certain districts of the metropolis it seems to be of an unusually virulent type. One curious point about the disease is its deceptive character, for many severe cases are discharged from hospital as convalescent, only to undergo a sudden and rapidly fatal collapse. The reason for this is somewhat obscure. Of all the methods adopted for the treatment of this complaint, none can be considered truly specific. The administration of drugs must be influenced by the clinical features that predominate in a given case. In those which present a parched skin, hyperpyrexia, and much restlessness, small doses of opium in the form of the aromatic chalk powder are indicated, but as the whole system is suffering from the effects of loss of fluid, rectal or subcutaneous injections

of normal saline or fresh sheep's serum are often of signal benefit. Warm baths are useful in almost all cases. Many physicians pin their faith to an initial dose of castor oil or grey powder followed up by such intestinal astringents as tannic acid or bismuth. Others prefer to administer intestinal antiseptics, such as the sulphocarbolate of zinc or the salicylate of bismuth. Alcohol is generally given as a stimulant, though it is questionable if minute doses of strychnine would not be more beneficial. Lavage of the bowel is one of the most important of the more modern therapeutic methods. Milk feeding is better dispensed with altogether from the first, its place being taken by albumen-water or whey. When the acute condition has subsided, small quantities of raw meat-juice may be given with advantage, a gradual return being made to milk.

#### Concerning Quacks.

"THERE be three things which are too wonderful for me—yea, four which I know not." If the wisest of men had lived in modern days he would have found it necessary to extend his list considerably, for even he could not have comprehended the infinite variety of wiles and dodges by which mountebanks manage to prey on the credulous. We suppose it is because the wings of the American eagle are so broad that that land of the free has become the special home of quackery and charlatanism. At any rate we think there is no other country in the world which could boast such a variety of gross superstitions at the present day as those to which Professor Osborne of Yale has drawn attention in a recent address. (a) With some of these, such as Eddyism, Dowieism, Osteopathy, we are more or less familiar in these countries, though happily the attempts to gain many converts have been so far unsuccessful. Of others we know less, and it is with some surprise that one finds what a thriving profession that of miraculous healer may be in the States. Thus, one "magnetic healer," who undertook to heal by absent treatment, was for some time in receipt of an income of five hundred pounds a day in fees of one pound per case. Another gentleman, established in Chicago, promises by the exercise of forceful thought addressed to disease germs, to drive them from the bodies of the sick for fees varying from two to fifty dollars a head. We learn, too, from Dr. Osborne, of the existence of a cult called "Ralstonism," which "is the lever that has been designed by the Creator for the work of uplifting the world." The Ralstonites are, however, an exclusive sect, and keep their positive doctrines secret. Among the more weird cults are mentioned many at whose tenets or methods we cannot even guess—Phenopathists and Venopathists, Cereopathists and Chiroprathics, Viticulturists and Vitaphysicists, Somatotherapists and Esoteric Vibrationists, the Koreshan

Universology, the Fire-Baptized Holiness Association, and, lastly, The Holy Rollers.

#### Sentimentality Among Guardians.

EVERY year or two notices a sudden outbreak of sentimentality among guardians of the poor with regard to the disposal of the bodies of those who have died while under their care. One does not notice an equal anxiety as to the comfort of those who have not yet died. From time to time, however, some guardian discovers with a feeling of pained surprise that the bodies of the unclaimed poor are made serviceable for anatomical purposes, and he immediately exerts himself to prevent such a "scandal." It is only a few months since an attempt of this sort was made in Dublin, and the other day there was a warm debate among the Hull guardians following on the discovery by one of their number that unclaimed bodies were occasionally sent to Cambridge for dissection. It is curious how difficult it is to convince people that the supply of bodies is a necessity of medical education, and that the ultimate object of medical education is the treatment of the sick and not the aggrandisement of the physician. And if medical education of proper sort be lacking, it is not the rich but the poor who will inevitably suffer. The rich can obtain the best medical advice, wherever it has to be brought from, but the poor must be content with what is at hand. Guardians of the poor have surely enough serious business with which to occupy their time without devoting themselves to the resuscitation of injurious and meaningless superstitions.

#### Physical Deterioration Committee.

THE appendix just issued to the report of the Committee on Physical Deterioration contains much valuable information, and though some of the returns therein presented are more imaginary than one had been led to expect, others give cause for grave anxiety. Thus one finds that at St. George's Barracks, London, where nearly one-third of all recruits are examined medically before enlistment, 374 per 1,000 are rejected as unfit, while in Manchester the proportion is even higher, namely, 490 per 1,000. The standard for recruits is not a high one, and it is significant that in two of the largest centres of industry nearly a third of presumably healthy young men cannot attain to it. Curiously enough, in Birmingham and Edinburgh the returns were much more favourable, only 192 failing in the former town, and 173 in the latter. Whilst in Edinburgh it is comprehensible that a large number of countrymen may present themselves for army service, and thereby raise the general level of fitness among the applicants, it is difficult to understand the marked difference between Birmingham and Manchester, unless it depends on the personal equation of the medical officer. The effect of good hygienic conditions on the physique of children is well shown in a set of tables prepared by Dr. Eichholtz, in which he compares the elementary school children of

(a) *Journ. Amer. Med. Assoc.*, July 2nd, 1904.

the open, healthy suburb of Wandsworth with those of the slum district of Lambeth. At four years of age the Lambeth children are on an average about seven inches shorter than the Wandsworth ones, and at fourteen years, three and a half inches. The lamentable fact is brought out, the poorest class of Lambeth child is worse developed than similar children in other large towns, such as Manchester and Leeds, and the difference between the poorer and richer classes is marked indeed. There is, however, one comforting fact, namely, that from photographs taken of children attending Lant Street Board School in the Borough in 1875-78, evidence is forthcoming to show that the physique of the poorest class of children is somewhat better to-day than it was twenty-five years ago. The whole of this appendix tells one decisive lesson—physical development depends on hygienic conditions of life.

#### Infantile Alcoholism.

THE gradual spread of the temperance movement in this country and the consequent lessening of disease due to alcoholism are matters for universal satisfaction. It is somewhat disquieting, however, to learn that in certain quarters parents are so little alive to their responsibilities as to give alcohol to babes and sucklings. For instance, the evidence at a recent inquest upon a boy of four showed that he had a regular allowance of beer. This child ultimately died of alcoholic poisoning as a result of drinking a mixture of rum and beer. It is well known that gin, or other strong spirits, is sometimes given to infants at the breast to "settle the milk," as it is thought, but really for the purpose of pacifying fretfulness. Can it be wondered that serious internal mischief is produced, to say nothing of damage to the nervous system which at this period of life is particularly susceptible? According to the *Alliance News*, the children of Normandy are in a very bad way. At a tender age they are given eau-de-vie, or "calvados," a spirituous liquor allied to gin, while brandy is frequently included in the daily rations of school children. The writer has there seen little girls intoxicated in the afternoon, utterly unfit to pursue their studies. We are glad to think that such a disgraceful state of affairs is not permitted in this country, though among the poor it is to be feared that infantile alcoholism is prevalent to a greater extent than is usually believed. More beer is drunk, unfortunately, than milk, and this latter commodity is often so diluted with water as to be of little real nutritive value. There is still much scope for tactful visitation by ladies and other workers who, by simple and kindly precept, will convince parents of the folly and wickedness of giving strong drink to their offspring.

#### Pneumonia and Public Health.

THE appointment by the New York Board of Health of a Commission of Experts to inquire into the prevalence of pneumonia in that city draws public attention to the ravages made by that

disease. We are so accustomed to regard tuberculosis as the principal foe which attacks the chest, that it comes on us as a shock to find that in several large American cities the deaths from pneumonia during the winter half of the year are more than double those from phthisis. In considering this proportion, however, it is to be remembered that the death-rate from phthisis is much lower than it was some years ago, owing to the success of preventive measures, and the question at present is whether pneumonia can be tackled with equal success. The case of the two diseases is very similar. Each is dependent on a special organism, which for its growth and multiplication requires a particular soil. *A priori*, there are two methods of attacking such a disease. We may either attempt to produce a soil where the organism cannot grow or we may attempt to eradicate the organism itself. In neither of the two diseases we are discussing can we apply the first method further than by developing a state of general good health. Our principal attack must be directed, therefore, against the organism itself, and the means adopted will be similar in the case of pneumonia to those that have been so far successful in the case of tuberculosis. Every attempt must be made to prevent the spread of infection by destroying with rigour all material where the *contagium vivum* may lurk. Nor will it be necessary to destroy the sputum of the obviously sick, but strictest regulations against expectoration in public places must be enforced. This is impressed on us all the more by the fact that many minor ailments, such as rhinitis and tonsillitis, are in causation pneumococcal, and infection from them may start a typical pneumonia in other persons.

#### Stature and Sickness.

AMONG physical characters there are few, perhaps, which influence the incidence of disease to such an extent as the stature of the individual. Those folk who quarrel with their height and devise some fresh means for altering it hardly realise the system of compensation which may be traced everywhere in Nature. In attempting to add cubits to their stature they ignore the fact that the balance of the whole being may be endangered by so doing. An interesting paper upon this subject was read before the British Association at Cambridge by Dr. P. C. Shrubbsall, who stated that individuals of high stature were more likely to be affected by heart disease, rheumatism, and tonsillitis, whereas short people were more often found suffering from tuberculosis, cancer and nervous diseases. Such generalisations have not, of course, been made without careful observation and measurement of a large number of patients, though it may not appear at first that there is any special connection between stature and disease-incidence. From the life assurance point of view the height of the proposer may influence considerably the decision of the medical examiner. Most authorities, for instance, are

agreed that if the stature exceeds five feet ten inches there is an increased risk, chiefly from heart affections. More than usual care should, therefore, be taken over the physical examination of the vascular system in a very tall subject, for it is well known that such people do not bear sudden strain or prolonged physical exertion at all well. The proportion between the height and the weight is even more important than the former alone. It may be advantageous at times to be head and shoulders above one's fellows, physically speaking, but a giant's stamina is not commensurate with his stature; indeed, the contrary is more often the case.

#### The Hygiene of Slavery.

EVEN the most rigid of New England moralists has had to admit that the emancipation of the slave has not been an entire success. It is true that in the emancipation a great principle of right triumphed, but principles have often the drawback of being injurious in their application in some of their details. Hence it is that the negro question in the States was by no means settled with the close of the Civil War. It is still the most serious social question in America, as the constant reports of alternate outrages and lynchings show. One of the lesser deleterious effects of the abolition of slavery, but one of particular interest to medical men, is the increased vulnerability of the negro race to certain diseases. Of these the most important is consumption, which has increased among the emancipated population to an extraordinary extent. Under the system of slavery the incidence of consumption on the black and white populations of the South was practically identical. At the present time to quote the figures from Charleston, while the incidence on whites has diminished by about twenty per cent., that on blacks has increased by 230 per cent. As regards insanity, the tale is similar. Previous to emancipation there were, as a rule, about sixty coloured patients in the Eastern Hospital for the Insane, Virginia, whereas now there are over 1,000. The cause of these changes is obvious enough. As slaves the negroes had to live regular, methodical, and, on the whole, healthy lives. Their houses were comfortable, their food good, their clothing sufficient. If sick, they had prompt medical attendance. They were, in fact, valuable living chattels, and as such their owners took care that their lives were rendered as sound and useful as possible. Now-a-days, however, they must shift for themselves. They are in the midst of a civilisation which they cannot understand, for which they are quite unfit. Overcrowded, lazy, dissipated, drunken, and ignorant of the evils resulting from such habits they are rendered an easy prey to tubercle. Formerly the negro had no need to think for the morrow—all was provided for him. Now his mind is subjected to the stress of competition in the most advanced civilisation of the world, a civilisation alien to him, and yet in which, if he is

to survive, he must take his place. It is no wonder that such conditions have conduced to the fearful increase of insanity above noted.

#### The "Live" Rail Peril.

THE convenience of rapid transit nowadays is not without its drawbacks, especially where electricity is concerned. It is, no doubt, an immense advantage to be conveyed swiftly from the suburbs to the city and *vice versa*, but with fresh forces fresh dangers have arisen. Several fatalities have lately occurred owing to contact with the so-called "live" rails upon railway lines, and the inquiry instituted by the Board of Trade has shown that the danger is by no means a theoretical one. It has been stated that the voltage of current upon the Metropolitan "tube" railway is not sufficiently high to produce a fatal result through mere contact. Death from shock ensues only when the body completes the circuit between the "live" and the running rail, and even then it would be necessary for the current to pass for an appreciable space of time. The fatal cases examined by Dr. Oliver and reported in the *Lancet* show that the burns inflicted by contact with the current-bearing rail are deep in extent, and of an unusually necrotic type. The question of protection of "live" rails is one which must be considered seriously by the railway companies and municipal authorities, and though it is impossible to cover in the rail throughout its whole length, yet adequate protection should be secured for the public at all accessible points. It is satisfactory to learn that guard rails are now being affixed upon the Underground Railway wherever a "live" rail, which is placed at the side of the track, is exposed to view. Another danger exists in the case of the electric tramways from the risk of the overhead "live" or trolley wire breaking. When such an event occurs, which happily, is not frequent, it is again necessary for the circuit to be completed *via* the human body before unpleasant consequences ensue.

#### PERSONAL.

It is not generally known among the medical profession that the speaker of the House of Commons is the son of a medical man, the late Mr. James Manby Gully, M.D., of Great Malvern.

THE new rector of Berlin University for the coming year is a member of the medical profession, namely, Professor Oscar Hertwig, Director of Medicine and of Philosophy, and Director of the Anatomico-Biological Institute, and member of the Academy of Science of Berlin.

THE British Association is going somewhat far afield for its next meeting, which is to be held at Capetown, under the Presidency of Professor George Darwin, of Cambridge.

MAJOR RONALD ROSS, C.B., F.R.S., has received the distinction of being elected Foreign Corresponding Member of the Paris Academy of Medicine.

A SIMILAR recognition of professional eminence has been conferred by the Academy upon Dr. Weir Mitchell, of Philadelphia.

PROFESSOR TILLAUX, President of the Paris Academy of Medicine, has been created *Grand Officier* of the Legion of Honour, by the President of the French Republic, who is himself a medical man.

THE appointment of Dr. J. E. M. Brown to be a District Surgeon in the service of the Federated Malay States has been confirmed.

DR. C. G. CASSIDY succeeds Dr. A. Bain, who has been transferred as Medical Officer in Charge of the Empanyana Leper Asylum, Cape of Good Hope.

MR. C. M. TUKE has been elected President of the West London Medico-Chirurgical Society for 1904-5.

THE resignation by Dr. Boyd of the Medical officership of South Shields, has created a vacancy for which there are now six selected candidates.

Miss McCaul and Miss Elaine St. Aubyn who, under the personal sanction of the Queen, went out last March to Japan to inspect and report upon the Japanese military nursing both in the field and at the base hospitals, are returning to England in the P. and O. steamship *Sardinia*, which is due at Tilbury on September 5.

### Special Correspondence.

[FROM OUR SPECIAL CORRESPONDENTS.]

#### SCOTLAND.

A GOVERNMENT CAUTION AS TO VACCINATION CERTIFICATES.—A memorandum as to the granting of certificates of successful vaccination has been issued by the Local Government Board, in which it is stated that the Board have had their attention drawn to the statements made in the reports of medical officers of health regarding cases of small-pox in children who presented no evidence of successful vaccination, either in the presence of local scars or in modification of the disease, although said by the parents to have been vaccinated. Similar cases have been observed in the course of inspection of contacts. Further inquiry showed that in many such cases a certificate of successful vaccination had been lodged with the registrar. The Board are satisfied that considerable laxity exists in the granting of such certificates, in respect that they are not always founded on personal inspection of the child after a sufficient interval, and occasionally have even been signed at the time of the operation, when its result was unknown, and when subsequent inspection would have disclosed failure. The certificate bears that the operation was performed by the person who signed it, and that it has succeeded, and if in either respect the certificate is false the signatory is liable to a criminal prosecution. A case which occurred in 1872 is quoted in which a sentence of four months' imprisonment was imposed on a practitioner who granted certificates of successful vaccination, though the vaccination had not taken effect, and the Board desire to make it publicly known that if in future any case of this nature comes to their knowledge, it will be their duty to report it to the Crown with a view to proceedings being taken.

#### BELFAST.

PUBLIC SANATORIA FOR PHTHISIS.—The question of consumptive sanatoria is much before the Belfast public just now, being discussed in the Municipal Council, in the Board of Guardians, and in the local

press. The Corporation has already decided to provide a sanatorium, and sites are being examined for the purpose at present. The Guardians have now decided that they also will provide a sanatorium, if the Local Government Board will permit, and have asked leave to purchase a house and grounds known as the "Abbey," at Whitehouse, some four miles from the city, on the north side of the Lough. Two strong objections have been raised to their proposed action: First, that they ought to combine forces with the Corporation and not attempt to run a separate sanatorium; and second, that if they do decide on a sanatorium of their own, the proposed site is unsuitable. As regards the first point, there can be no doubt that two sanatoria will cost more than one, and the ratepayers must find the difference. The Corporation propose to start with a scheme for 100 patients, and are willing to take patients from the workhouse at a fixed rate of payment, provided they are considered curable. The Guardians say that the Corporation scheme is too small to be of use, as they themselves have usually 200 to 300 consumptives in the workhouse infirmary. Further, they say that they must make provision for all cases, curable or otherwise, and difficulties would arise in selecting those for treatment in the Corporation sanatorium. As regards the question of site, if it is decided to provide a workhouse sanatorium, the "Abbey," though not an ideal site, is probably as good as could be found. It is true that it is on a cold clay soil, not well drained and near the muddy shore of Belfast Lough, but it is 160 feet above the sea, has a south aspect, some trees to shelter it on the north, and it is cheap.

THE SMALL-POX OUTBREAK.—The general outbreak of small pox which threatened Ulster a fortnight ago seems to be passing off without doing much damage, due no doubt to the very vigorous means which were adopted to combat the disease in every town in which it appeared. After Belfast, the worst outbreak was in Armagh, where twenty-one cases occurred, five being severe confluent cases, eleven discrete, and five modified. As the accommodation was insufficient, a shed divided into two wards each to contain fifteen patients, was built at a cost of £200. No fresh cases have appeared in Omagh, Monaghan, or Enniskillen. Three severe cases are under treatment in Castleblaney workhouse. As is always the case, the scare is having some excellent results. For one thing, the inhabitants of the districts where small-pox has occurred are flocking in hundreds to be vaccinated. Then it has led the Guardians in many of the country towns to set their houses in order, and carefully consider the accommodation available if cases should occur in their district, for whatever shortcomings the ratepayers may overlook, they will certainly not forgive any slackness in dealing with small-pox. It is extraordinary how strong the dread of this disease remains, in spite of the fact that generations have passed away since it devastated the country.

#### THE DIMINISHING BIRTH-RATE.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—While weighing the gage thrown down by Dr. Taylor with a view to testing the justice or otherwise of his challenge, up rushes LL.D. with lance pointed and vizor down. This anonymous champion straightway assails me fiercely, not as a neutral critic, but as Dr. Taylor's sworn foe. Let us see what wounds he has inflicted.

On p. 33 of your issue of July 13th, I said, "In 1884 the total birth-rate (of the United Kingdom) stood at 31." It should have read: The average of the five-yearly period, 1884-1888, stood at 31.2. To refute my figures for the United Kingdom Dr. Taylor quoted the returns for England and Wales in 1884. That error is rendered none the less

grotesque by LL.D.'s showing that my figure of 31 for the total birth-rate of 1884 is wrong. LL.D. strikes wide, however, when he says that my argument "founded on the assumption that the birth-rate in 1884 was only 31, therefore falls to pieces." That is true so far as it goes, but the main argument of that part of the article is independent of the figures 31. Accepting LL.D.'s correction, I see no reason to alter my very mild and moderate conclusion as stated in the following passage: "My figures, I am aware, may not be absolutely accurate but I think it may be safely concluded that the fall in the *married* birth-rate is much less than that shown by Dr. Taylor. In a word, his figures are vitiated at the outset by his failure to consider the facts of the extra-marital condition of illegitimacy. It is impossible, therefore, to accept his (Dr. Taylor's) fundamental proposition that 'we may take the birth-loss in the United Kingdom as due to causes operating in the married life of its inhabitants.'" Let LL.D. justify Dr. Taylor's logical blunder if he can; it will not be done by pointing to a fortunately non-essential blunder that has crept into my article.

Dr. Taylor shows an equal misconception of what I say when he wrote on August 10th, that I "build my main argument on the 1884 rate being 31." I do nothing of the kind. I assure both him and LL.D. that the single one of my various arguments concerned is so little affected by the figures that I am willing to cut out of the passage in my article (p. 32 MEDICAL PRESS AND CIRCULAR.), from "his figures," down to "condition of illegitimacy."

My abandonment of these figures disposes of LL.D.'s further attack on my estimate of what would happen had there been no decline in the rate of illegitimacy. I am not an advocate on one side or the other, and am open to correction. The fallacy is self-evident of Dr. Taylor's assumption that the decline in the birth-rate is due to causes affecting married life, when he fails to consider the illegitimacy included in the total rates.

Lastly, the social and economic conditions are so absolutely different in New South Wales that conclusions founded on an investigation there would have little application to the United Kingdom. In New South Wales, for instance, there is universal suffrage, and members of Parliament are paid for their services. These two facts alone will show the vast gulf between the two countries, which I still maintain may be described by the homely comparison, familiar enough in my own Western county, of the difference between chalk and cheese. I have often noted how the simple directness of hobnailed philosophy nettles those who love subtleties and sweeping generalities rather than rigid logical analysis.

Why does not LL.D. come into the light of day and let us know who he is? Surely he is not afraid of injury to some great reputation and authority? To my mind no man, without signing his name, has any right to pen such a sentence as that of LL.D.'s when he says: "The loose way in which Dr. Walsh handles figures puts him almost outside the pale of statistical controversy." The question naturally arises, who put LL.D. inside that pale? There is only his letter to judge by, and at the end of it we find our old, old friend, the *petitio principii*. In accusing me of favouring a policy of "smug complacency," LL.D. simply calls names where he should furnish formal proof. This question-begging shows that whatever his years and experience he does not always observe the rules of sound argument. If he can produce a "crushing refutation" to my "fallacies" such as he says is to be found in the Report of the New South Wales Commission, I shall be the first to welcome his exposure, provided it stands the tests of formal critical examination.

I am, Sir, yours truly,  
DAVID WALSH.

Hanover Street, London, W.  
August 26th, 1904.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.  
SIR,—Will you allow me to answer the questions submitted by your correspondent "Qualified Assistant?" On consideration, it must be obvious to him that the special question whether "A" or "B" did right to marry, must depend on many reasons—on their age, education, characters, habits, and circumstances, and in the cases before us I have altogether insufficient data on which to form an opinion. But whether married or not, I do hold that strict temperance in all allowable sensual gratification, and abstinence from that which is inallowable, is right and good, not only for the individual, but for his or her future progeny.

Such principles carried out in practice will not result in too early marriage nor in the production of the greatest possible number of children, but should result, I believe, in the moral growth of the individual, and, if married and fertile, in vigorous, healthy, and sufficiently numerous offspring.

Applying such principles to the particular cases cited, I hold that even a country practitioner and a poor curate cannot be justified in using artificial means to prevent conception.

Particular cases may labour under unjust disabilities which demand redress, but two wrongs will not make a right.

The common labourer, in our great cities (as Mr. Rowntree has shown), is too often not paid a living wage, sufficient for himself, his wife and a family of four children, but is underfed, under-housed, and underclothed. This is sad and shameful, but (if it were possible) it would be a poor remedy to sterilise the labourer or limit his family to one. The injustice of insufficiently paid labour would be thereby perpetuated.

Similarly, in many cases the stipends of the clergy, and especially of curates, are deplorably and disgracefully inadequate. As the world is at present constituted, the practical philanthropist must hope that all these cases of injustice will force themselves more and more on the notice of the people until they refuse to grow rich or comfortable or instructed on the enforced charity of those that serve them.

It is no true remedy for the clergy to sit down under their grievances, and to practise and encourage an unnatural sexual life which must be more or less degrading and carries with it no real element of cure.

Such a course will only perpetuate injustice and lower the general ideal of religious life among both clergy and laity.

Exactly the same principles, I believe, apply to the nation as to the cases I have considered. Let us admit that England is too small for the genuine natural increase of its population. It is the coward at heart who, because of this, will resort to methods of sexual congress "habitually adjusted to a certainty of imperfection." Rather should he busy himself in establishing schools of emigration in which his children shall be fitted for pioneer life—in finding new markets for his goods, and in bringing reliable knowledge and assistance to the very doors of the youthful and enterprising. It may well be doubted whether the higher ideals I am striving to preach do not demand some alteration in present economic conditions—a change in the direction of greater equality in the distribution of wealth. If so, let us attack the problem bravely and seriously. To fold our hands and avoid present pain at the cost of future decadence, is a miserable and destructive policy for the nation as well as for the family.

I am, Sir, yours truly,  
JOHN W. TAYLOR.

22, Newhall Street, Birmingham.  
August 25th, 1904.

#### MEDICAL GEOLOGY.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.  
SIR,—Geology is a wide science. To some the various strata of our earth's cortex is of interest, and

their relation to each other, and the forces that have disturbed them. The chemist, the mineralogist, and the engineer may have to study some branch of geology; and there is no doubt but that some knowledge of geology should be possessed by the members of the medical profession. When we are analysing the climatic character of any country or locality, the first thing to look to is the nature of the soil. In England the differences are great. We may find two places on parts of our coast where temperature, rainfall, sunshine, and other external influences are much the same, but where the conditions of the atmosphere differ much. Now that the question of open-air treatment of lung diseases is of interest, it would be well to be careful to study the soil, as upon that so much depends. It would be well for doctors to know the differences between clay, chalk, greensand, and Silurian, geologically, chemically, and medically. Without such knowledge, we are not competent to deal properly with the wide question of climate.

I am, Sir, yours truly,

R. L.

## Obituary.

SURGEON-MAJOR FRENCH, M.B.ED.,  
M.R.C.S.ENG., L.R.C.P.

MAJOR GEORGE BROOKE FRENCH, of the Indian Medical Service, who died last week at Tunbridge Wells, was a graduate of the University of Edinburgh. He obtained his M.B. in 1894, and was prizeman in a number of subjects and took first-class honours in many others. He was also gold medallist in medical jurisprudence and prizeman in surgery in the Edinburgh School of Medicine. He qualified as a member of the Royal College of Surgeons, England, in 1885, and as a licentiate of the Royal College of Physicians, London, the following year, in which he joined the Indian Medical Service. In 1891 he took part in the expedition to Manipur, for which he had the medal with clasp; and in September, 1898, became a Major.

## Literature.

### PHYSICAL DETERIORATION.(a)

It is a significant fact that the progress of civilisation is fraught with disadvantages to the lower strata of society, which, it is to be feared, more than compensate for the ethical evolution and enhanced comfort of the more favourably situated members of the community. In spite of philanthropic and municipal efforts overcrowding proceeds apace, and the sanitary condition of our slums is the despair of sanitary experts. Here and there one perceives a ray of light, authorising the hope of better times ahead, such, for instance, as the spread of the sanitary gospel of fresh air, the importance of cleanliness and so on. But we are confronted with the fact that a large proportion of our labouring population live and move and have their being under conditions which render fresh air and personal cleanliness physical impossibilities. It is estimated that 3,250,000 persons in the British Isles live in overcrowded dwellings, that is to say, with an average of three persons in a bedroom; we are told that in York, for instance, 228 houses have between them only 33 closets, while 442 have only 30 water-taps, the tap often being placed in the wall of the w.c. How are people to get fresh air in a climate like ours with an average air-space of only 200 cubic feet per individual.

These lamentable conditions are notorious, so notorious that it is unnecessary to allege concrete examples, since every city furnishes a parallel. The physical deterioration which such conditions engender, as set forth in detail on a bed-rock of personal observation by the author, is but what one must expect. Moreover, the effects of unhygienic surroundings are enhanced by the carelessness and ignorance of mothers in respect of the alimentation and general care of

their offspring, resulting in a lamentable waste of infant life.

But the remedy! Obviously many of the conditions are the consequence of a social system which presses hardly on the wage-earning classes, and admit of but slow and uncertain amelioration. It is idle to promulgate laws and enforce measures for the prevention of overcrowding when every rookery razed to the ground intensifies the overcrowding in the neighbouring area, when rapacious and unscrupulous landlords are allowed to exact rents which, in amount, are inversely to the healthiness of the tenements.

Nevertheless, the author, who has gone very thoroughly into the subject, is enabled to make various practical suggestions to attenuate, if not to arrest, the progress of physical deterioration. The medical inspection and physical culture of school children, their better alimentation, the training of mothers, and the dissemination of a knowledge of elementary hygiene—these are measures which would certainly tend to prolong life and to raise the physical standard of the rising generation. Then, too, the alimentation of the adult population is a question of the greatest importance, both from physiological and economical points of view. If we can enlarge the dietetic horizon, if we can impart a knowledge of how to choose good food and how to cook it, we shall improve the physical condition and increase the comfort of the labourer's existence, and *pro tanto* lessen the temptation to alcoholic indulgence. We are, however, inclined to agree with the author that no great progress can be hoped for unless the matter be taken in hand from the earliest stage of child life, beginning by securing an adequate supply of clean milk for hand-fed infants. In towns, at any rate, it must be difficult to make up for shortcomings during infancy.

It is generally assumed that the tendency of the rural population to aggregate in towns is the result of a natural law which we are powerless to circumvent. But in reality it is nothing of the kind. Farm labourers leave the land because they are inadequately paid, and because of the wearisome monotony of their lives. They have to live in tumbledown cottages, when they are fortunate enough to find one in which to lay their heads, and their living is of the plainest. In old age they have only the workhouse to look forward to. Were there a system which would enable them to live in humble comfort, with a cottage and a garden of their own, if their employers only took the trouble to provide some sort of amusement for their scanty hours of leisure, no such wholesale emigration to the towns would occur. The system of "small holdings" is the one great inducement that can be offered to the farm labourer to remain in the country.

The author has discussed these points, and many others, in a magisterial manner, validating the statements by copious references to Blue Books and official reports. She establishes the existence of a wide-spread evil which threatens to sap the virility of the race, she studies its etiological factors, and she proposes the appropriate remedies. Truly the task is a heavy one, but it is not beyond the power of man to compass its ultimate achievement. The author has no panacea to offer us, but she makes it clear that we have the remedy in our own hands. It is a matter for individual effort in the main, laws being inoperative as against ignorance and indifference. We would appeal to all who are in earnest in this crusade against disease and racial decadence to read this eloquent indictment and to co-operate in the endeavour to inaugurate a happier future.

### SWAFFIELD ON LAPAROTOMY WOUNDS.(a)

In this most original little work Dr. Swaffield has collected the detailed methods adopted by some fifty of the leading Continental surgeons in closing the

(a) "The Closure of Laparotomy Wounds as Practised in Germany and Austria; including Detailed Methods and Views Communicated by over Fifty Leading Surgeons." Edited and translated by W. H. Swaffield, F.R.C.S., M.D. London: J. and A. Churchill. Pp. 72. 1904.

(n) "Physical Deterioration: its Causes and the Cure." By A. Watt Smith. London: John Murray. 1904. Price 6s.

incision made in abdominal cœliotomy. The different methods enumerated may be roughly divided into two groups:—Those in which a simple through-and-through suture is adopted, and those in which some method of suture in layers is adopted. We note that eleven alone of the fifty operators, whose views are given, are in favour of the former method, and that the majority of these, while they are all names of great weight, still represent the older, rather than the younger, school of surgeons. This coincides very closely with our own views on the subject, and we doubt that there is any future before the simpler method. To believe that a through-and-through suture can be made to bring about the same natural restitution of the parts that can be obtained by suture in layers is to us impossible. It may be, and we do not doubt it in this case, that an exceptional operator can obtain excellent results by the through-and-through suture, but even if he does do so, it is beside the question. What is required is the method which will give the best results in the hands of the ordinary surgeon, without demanding the expenditure of an undue amount of time. We are sorry that Howard Kelly's method of suturing has not found a place in this little *brochure*, as it has always appeared to us to be one of the best, if not the best of methods.

#### "THE EDINBURGH MEDICAL JOURNAL. (a)

The present volume (No. XV) of the *Edinburgh Medical Journal* maintains the high standard of excellence attained by its predecessors. The original contributions are twenty-seven in number, and the majority of them are of a practical character. We need do no more than quote some of the titles to show how helpful the literature of the volume must be to men in active practice. "Strangulated Hernia," "The Cardiac Muscle," "The Stools of Dysentery," "The Treatment of Bronchiectasis," "Cæsarean Section for Contracted Pelvis," "Fibrinous Bronchitis," and "The Neural Factor in Heart Disease." Besides all this the volume contains a series of articles on "The Insanities and Criminal Responsibility," by Sir John Batty Tuke, and Mr. C. R. A. Howden, Advocate, which is of permanent value, and giving, as it does, the ripe experience of such a distinguished alienist as Sir John Batty Tuke, cannot be overlooked by those specially concerned with the study of mental diseases and social reforms. Under the heading "Recent Advances in Medical Science," the different provinces of medical science are passed under review in each monthly number: Medicine, surgery, obstetrics, gynaecology, therapeutics, pathology, diseases of the ear, nose and throat, and public health; this last section is edited by Dr. J. Buchanan Young, and is one of the most interesting summaries of the progress of preventive medicine with which we are acquainted. We have occupied an unusual amount of space in this notice, but we feel that we could not otherwise have given our readers a true picture of the wealth of information the journal contains. Well-selected matter of a practical character, conveniently arranged and excellently designed to meet the requirements of the student and the busy practitioner. The printing, illustrations, and paper are all good, and the volume reflects credit on all concerned in its publication.

#### BLAND-SUTTON ON TUMOURS. (b)

In the third edition of this admirable work the author has made some important alterations and additions. The term "epithelioma" has been abandoned and replaced by the phrase "squamous-celled cancer." We regard this change as a good one, on the ground that it places the nomenclature and classification of these tumours on a more satisfactory basis. Another marked step in advance is the separation of ovarian fibroids and myelomata from the sarcoma group, and

their recognition as separate entities. We think it probable that in a later edition the author will deal similarly with "deciduoma malignum," which he provisionally places, in this edition, among the sarcomata. We should have liked to see a fuller account of these tumours, with some illustrations; but no doubt the reason of the brief description given is to be found in the uncertainty which the author regards as still prevailing as to the true nature of "deciduoma." As a matter of fact, a very important contribution to the subject was made soon after this volume was published. Mr. Bland-Sutton has amplified the section on uterine fibroids, and has done excellent service to the sufferers from these tumours by demonstrating the modes in which fibroids imperil life. In the second edition the section on echinococcus colonies was omitted, but, yielding to representations from readers who regretted the omission, the section has been restored with additions, which render it a valuable feature of the book.

It is not necessary to enter upon a detailed criticism of a book which is so well known, and which may be ranked as a classic. This third edition is a worthy successor to the previous ones, and fully maintains the author's high reputation as an authority on the subject. To any of our readers who may not previously have made the acquaintance of "Tumours" we cordially recommend it as a book from which they will derive a vast amount both of pleasure and of profit.

#### RIDDELL'S MANUAL OF AMBULANCE. (a)

In revising this well-known ambulance hand-book the author has taken the opportunity of extending its already recognised utility by making certain material additions to it. We would particularly note the excellent new series of full-page illustrations of stretcher drill which are extremely well reproduced. He has also added a chapter on electrical accidents, while that on the organisation of ambulance classes has been considerably amplified, and, we think, improved. The chapter on anatomy and physiology contains some very good plates, while the explanatory text treats the subject in a very lucid manner. In dealing with ambulance transport and stretcher drill, the author gives what is perhaps one of the best accounts of these subjects which can be obtained. It is not only clear and to the point, but it is so well illustrated that the student should have no difficulty in mastering the details of this very important branch of ambulance work.

It is a pity that the author should have inserted a chapter on the after-treatment of ambulance cases. Surely the principles of first aid do not come into operation once that aid has been given. Therefore we think more harm than good is likely to ensue from the insertion of temperature charts and figures of Leiter's tubes. In a subsequent edition we should certainly advise the withdrawal of this chapter altogether. Apart from this, we can thoroughly endorse all the good things that have been said regarding previous editions of this work. This, the latest, edition will be found not only an admirable guide for students, but a useful work of reference for teachers.

#### GOWERS' MEDICAL OPHTHALMOSCOPY. (b)

It is now twenty-five years since this important work was first issued. Since then the science of ophthalmoscopy has undergone many changes, and improvements in the instruments used in its study, together with advance of knowledge of the morbid

(a) "The Edinburgh Medical Journal." Edited by G. A. Gibson, M.D., F.R.C.P. Ed., and Alexis Thomson, M.D., F.R.C.S. Ed. New Series. Vol. XV. Edinburgh and London: Young J. Pentland, 1904.  
(b) "Tumours, Innocent and Malignant." By J. Bland-Sutton, F.R.C.S. Third edition, with 312 illustrations. 556 pp. Cassell and Co., Ltd. 1903.

(a) "A Manual of Ambulance." By J. Scott Riddell, C.M., M.B., M.A., Senior Surgeon and Lecturer on Clinical Surgery, Aberdeen Royal Infirmary, &c. Fifth Edition. Revised and Enlarged. 4s. London: Chas. Griffin and Co., Ltd. 1904.

(b) "A Manual and Atlas of Medical Ophthalmoscopy." By S. Wm. B. Gowers, M.D., F.R.C.P., F.R.S., Hon. Fellow, Royal College of Physicians of Ireland, Consulting Physician to University College Hospital, &c. Fourth Edition. Edited by the Author and Marcus Gunn, M.B., F.R.C.S., Surgeon to the Royal London Ophthalmic Hospital, Ophthalmic Surgeon to the National Hospital for the Paralysed and Epileptic, 14a, net. London: J. and A. Churchill, 1904.

conditions observed, have made it incumbent upon the author to call in the aid of an ophthalmic surgeon, so as to bring the work thoroughly up to date. He has been fortunate in obtaining the services of Mr. Marcus Gunn, "whose experience," as the author aptly remarks, "has been wide in range and wisely used."

The general plan of the work is so well known that we need hardly do more than refer to it here. In the first portion retinal and optic nerve changes are dealt with *seriatim*, the condition of optic neuritis being treated of in a particularly exhaustive and complete manner. The second portion, however, is the one which is most useful to the physician, as in it the ophthalmoscopic changes occurring in special diseases are fully gone into. In speaking of tuberculous meningitis, Gowers points out that tubercles of the choroid are less frequently found than in general tuberculosis without meningitis. He gives 65 as the percentage of cases of locomotor ataxia associated with optic atrophy, and incidentally mentions that "tabes must be ascribed to the action on the nervous system of a post-syphilitic toxin."

The appendix consists of a series of valuable autotypes which have been somewhat improved in this edition. They are certainly beautiful reproductions, and illustrate in a singularly clear way the various morbid conditions met with in ophthalmoscopic examination. While they can never replace practical work, these plates are of the greatest possible service for reference by those who have difficulty in making a diagram of the ophthalmoscopic appearances presented on the examination of any particular case.

There is no work in any language to compare with the one under review. It has hitherto been regarded as a standard work of reference on medical ophthalmology. This new edition is certain to increase its popularity not only in this country, but also abroad, and it must for many years to come remain the authoritative expression of all that is best in British and foreign teaching on the subject.

## Medical News.

### The Plague.

THE following telegram from Sir Cavendish Boyle, Governor of Mauritius, has been received at the Colonial Office:—For week ending August 25th, ten cases of plague, five fatal.

### Allen Lunatics.

A RETURN was recently presented at the Lancashire Asylums Board meeting at Preston showing the number and nationality of alien patients in the asylums. The total numbers were 88 males and 46 females. Of these six were Americans, two Arabs, two Austrians, one Belgian, one British St. Vincent, one Dane, two Dutchmen, five Frenchmen, 28 Germans, 11 German Jews, one German Pole, one Greek, 12 Italians, five Norwegians, one North American negro, seven Poles, one Portuguese, two Roumanians, seven Russians, four Russian Jews, one Russian Pole, one South African, two South Americans, two Spaniards, 13 Swedes, one Morocco Jew, and 14 whose nationalities were unknown.

### Röntgen Rays for the Russian Army.

It is stated that the Russian hospital which is being sent to the seat of War by the citizens of Moscow will have a first-rate Röntgen ray outfit. From the report, it would almost seem as if the advantages of that method of diagnosis had not yet been widely adopted by the medical profession in Moscow.

### Bequests to Medical Charities.

Under the will of Mrs. Jane Bowron, of Hove, who died on July 17th last, the sum of £2,000 is bequeathed to the Sussex County Hospital; £1,500 to Lady Kinnaird Memorial Hospital for Women, at Benares; £1,500 to the Agra Medical Missionary Training Institute, affiliated to the Medical Missionary Society, at Morning-side Park, Edinburgh; and £1,000 to the Brighton, Hove, and Preston Medical Dispensary.

## PASS LISTS. University of London.

At the general intermediate examination in medicine for internal students held in July, the following candidates were successful:—

Ella Mabel Barker, Charles Anthony Basker, Harold Garfield Bennett, Sylvia Rose M. Blackstone, Mary Alice Blair, Harry Blakeway, Gerald Tyler Burke, Thomas W. Higgins Burne, Angel Camacho, Thomas E. Ashdown Carr, Henry Joseph Cates, Herbert Stanley Chate, Bertram Walter Cherrett, Arthur Beauchamp Coomber, Herbert Rees Davies, Kenelm Hutchinson Digby, Reginald Lionel Ernest Downer, Sheldon Francis Dudley, Robert Cecil Turle Evans, Marmaduke Fawkes, Allan Bains Fearnley, William Stephen Fenwick, Janet Marcia Fische, Alexander Fleming, Sidney Frank Fouracre, Ernest William Giesen, Sidney Wilfred Grimwade, Edith Mary Guest, John Hadwen, Eric Henry Rhys Harries, Henry John Henderson, Tom Shadick Higgins, John Ernest Hodson, Hendrik Houwink, Douglas Walter Hume, Mary Sophia Jevons, Elizabeth Herdman Lepper, Clifford Antony L. Mayer, Marian Mayfield, Minnie Merrifield, Ethel Mary Morgan, William Poole Henley Munden, Frederic Miller Nield, Henry John Nightingale, Humphrey Nockolds, Edgar Lionel Robert Norton, Charles Aubrey Pannett, Walter Patey, Catherine Payne, August Frederick Perl, Arthur John Scott Pinchin, Edward John Price, Mona Dew Roberts, Richard Cadwaladr Roberts, Henry Charles Samuels, William Octavius Sankey, Marie Simpson, Eliza Macdonald Smith, Henry Joste Smith, George French Stebbing, Alfred K. B. R. W. Taylor, Douglas Compton Taylor, Alfred Charles Foster Turner, James Richard Henry Turton, Winifred Emmeline Watts, Harry Gordon Webb, Leonard Henry Wootton, and Carl Ernst Zundel.

At the intermediate examination in medicine for external students held in July, the following candidates were successful:—

Laurence Ball, Sydney Herbert Booth, Ernest Frederick Finch, Robert Applegarth Hendry, James Ernest Middlemiss, Edward Selby Phipson, Harry Richardson Rawlings, Arthur Toulmin, Arthur Henry Turner, and Joseph W. James Willcox.

## University of Oxford

THE following degrees in medicine were conferred during the summer term:—

*Doctors of Medicine.*—Thomas E. C. Cole, Edgar W. Willett, William A. P. Waters, Gustav J. Schorstein, and Arthur E. Boycott and John D. Rolleston.

*Bachelors of Medicine and Surgery.*—W. B. Billinghurst, A. C. Inman, A. F. Hertz, A. E. A. Loosely, J. H. Thomas, R. D. MacGregor, and P. A. Mansfield.

Degree days are announced as follows for the coming term:—Thursday, October 20th; Thursday, November 10th; and Saturday, December 17th. Examinations for scholarships offered in natural science will be held on December 6th, at Balliol College, Christ Church, and Trinity College; on December 13th, at Lincoln and Magdalen Colleges; on January 17th, 1905, at Jesus College; and on March 14th, 1905, at Keble College.

## Society of Apothecaries of London.

At the examinations held in August, the following candidates passed in the subjects indicated:—

*Surgery.*—R. H. Cooper (Section II.), A. W. S. De Vine (Sections I. and II.), E. F. W. Hoare (Sections I. and II.), A. C. Story (Sections I. and II.), and R. H. Terry (Section I.).

*Medicine.*—G. B. Messenger (Section I.), C. S. Scott (Section II.), I. C. Thorburn (Sections I. and II.), A. B. S. Todd (Section II.), and S. H. R. Welch (Sections I. and II.).

*Forensic Medicine.*—C. W. S. Boggs, E. F. W. Hoare, J. E. Jones, I. C. Thorburn, and H. M. Waller.

*Midwifery.*—W. G. H. Cable, and W. R. Elliott. The diploma of the Society was granted to the following candidates entitling them to practise medicine, surgery, and midwifery:—R. H. Cooper, A. C. Story, A. B. S. Todd, and S. H. R. Welch.

## Notices to Correspondents, Short Letters, &c.

**CORRESPONDENTS** requiring a reply in this column are particularly requested to make use of a *distinctive Signature or Initial*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

**ORIGINAL ARTICLES** or **LETTERS** intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

**CONTRIBUTORS** are kindly requested to send their communications, if resident in England or the Colonies, to the Editor at the London office; if resident in Ireland, to the Dublin office, in order to save time in re-forwarding from office to office. When sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

**REPRINTS.**—Reprints of articles appearing in this journal can be had at a reduced rate providing authors give notice to the publisher or printer before the type has been distributed. This should be done when returning proofs.

**M. D. CANTAB.**—The only way of protecting yourself against such an unpleasant contingency in future is to refuse to give evidence before being paid your fee. It is open to you to refuse this in the witness-box *before* you are sworn.

### THE PRESERVATION OF RUBBER CATHETERS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

**SIR.**—Can any of your readers tell me how to keep red rubber (flexible) catheters from becoming "sticky." I find if they have been in constant use for about a month they swell and lose their gloss I have tried boiling, etc., but all to no use.

Yours truly, F. WINDER.

A correspondent writes:

**SIR.**—Perhaps some of your readers can give me some advice in the following case: An officer, age 45, still serving in militia, of good general health, applies for insurance. He has served through various arduous campaigns but escaped serious illness or injury except on one occasion. He was then shot through the thigh with a low velocity bullet, and had a septic wound that caused extensive damage to the leg. He lost two stones in weight, and which he has not regained after ten years interval. He is organically sound, so far as one can tell, except that the specific gravity of urine is 1006, but not excessive in quantity. This life is clearly not first-rate. Is it insurable?

Yours faithfully, C. F.

### THE DIMINISHING BIRTH-RATE.

Vide THE MEDICAL PRESS and the Bishop of Ripon.

I thank the foresight, commonsense,  
Which on my birth have smiled  
And made me in this crowded world  
An only healthy child.

The Psalmist, had he lived to-day  
In truth would not be able  
To call him blessed who has swarms  
Of children round his table.

My bishop and my doctor both  
Quote dimly statistics,  
The Politician, on his side  
Quotes overcrowded districts.

My mother knows were she to aid  
A still decreasing birth-rate  
A fight would come to keep paid up  
The gas bill and the poor rate.

I thank (as I remarked before),  
Although I'm rather lonely  
That commonsense which keeps me still,  
My parents "one and only."—ONLOOKER.

**SYLVANUS** writes that he has received a letter from a consultant physician under the following circumstances. A patient came under his care with secondary syphilis. It appears that this patient was sent to the consultant by a mutual friend who paid the first fee, but was not prepared to pay for a course of treatment. The patient then came under our correspondent's care. A few days later a note came from the consultant recommending the administration of iodide of potassium, together with mercury, on account of the high temperature, and saying how the case had come under his notice. Our correspondent asks what he should do.

[In our opinion, as the consultant has gone out of his way to prevent any misunderstanding, it would be only courteous of our correspondent to write a detailed answer, and if he does not agree with the suggested plan of treatment to state briefly his views on the point.—Ed. M. P. & C.]

### A HOSPITAL CURIOSITY.

When pulling down the old Waterloo Hospital for Children for the new building, a discovery was made under the foundation stone of a glass tablet, with the names of the founders and date, &c., encrusted therein. Also a small copper coin, and copy of the Annual Report of the Hospital for the year 1822, contained in a bottle, and all in an excellent state of preservation. Among the Patrons and Vice Patrons of the Institution were the following interesting names:—The Duchesses of Kent, Northumberland, and Princess Augusta,

the Dukes of York, Sussex, Grafton, Rutland, Beaufort, &c., the Rt. Hon. Robt. Peel, Sir Humphry Davy, and other well known People.

## Vacancies.

**Bradford Poor-Law Union.**—Medical Officer of Sanatorium.—Resident Medical Officer. Salary £100 per annum, with rations, apartments, and washing. Applications to George M. Crowther, Clerk to the Guardians, 22 Manor Row, Bradford.

**Cardiff Union.**—Assistant Medical Officer. Salary £120 per annum, with rations, apartments, attendance, and washing. Applications to Arthur J. Harris, Clerk, Union Offices, Queen's Chambers, Cardiff.

**The Zanzibar Government.**—Medical Officer for the Island of Pemba. Salary £280 per annum. (Applications to W. S. W. N., care of Streets, 30 Cornhill, E.C.)

**Down District Lunatic Asylum, Downpatrick.**—Junior Male Assistant Medical Officer. Salary £100 per annum, with furnished apartments, board, washing, fuel, light, and attendance. Applications to the Resident Medical Superintendent.

**Wandsworth Union.**—District Medical Officer. Salary £100 per annum. Applications to F. W. Piper, Clerk, Union Offices, St. John's Hill, Wandsworth.

**Great Yarmouth Hospital.**—House Surgeon. Salary £90 per annum, with board, lodging, and washing. Applications to Richard F. F. Ferrier, Hon. Secretary, 33 Hall Plain, Great Yarmouth.

**Hamstead General Hospital.**—Resident Medical Officer. Salary £120 per annum, with rooms, coals, and gas. Applications to George Watts, Secretary.

**Boothle General Hospital, Liverpool.**—Junior Resident. Salary £80 per annum, with board and laundry. Applications to the Secretary, Boothle Hospital, Derby Road, Boothle.

**Ballinasloe District Asylum.**—Second Assistant Medical Officer. Salary £140 per annum, with cash allowance of £25 in lieu of rations, &c. Immediate application to the Resident Medical Superintendent, James St. L. Kirwan. (See Advt.)

**Open-air Sanatorium for Consumptives, Limley Stoke, near Bath.**—Resident Medical Officer. Salary £200 per annum. Applications to "Chairman," N.A.P.C., 84 Park Street, Bristol.

## Appointments.

**GREENE, ARNOLD J.,** M.B.O.S.Eng., L.R.C.P.Lond., Honorary Assistant Medical Officer to the Royal Albert Edward Infirmary, Wigan.

**JACKSON, F. W.,** L.R.C.P.Lond., M.B.C.S., Certifying Surgeon under the Factory Act for the Market Basen District of the county of Lincoln.

## Births.

**BISSHOPP.**—On August 26th, at Parham House, Tunbridge Wells, the wife of Francis E. B. Bishopp, M.A., M.D.Cantab., M.R.C.P. Lond., of a daughter.

**O'DWYER.**—On August 17th, at Sunnyside, Tipperary, the wife of Dr. Joseph O'Dwyer, of a son.

**RADFORD.**—On August 3rd, at Nairobi, East Africa Protectorate, the wife of William J. Radford, F.R.C.S., of a son.

**SWAIN.**—On August 25th, at 4 Victoria Square, Clifton, Bristol, the wife of James Swain, M.B., M.D.Lond., F.R.C.S., of a daughter.

## Marriages.

**BRONHALL—DRAKE.**—On August 24th, at St. Peter's Church, Mount-sorrel, Loughborough, Ernest Bronhall, M.B.O.S.Eng., L.R.C.P. Lond., Raw'entall, to Beatrice, only daughter of the late Rev. Thomas Drake, M.A., vicar of St. Peter's, Mountsorrel.

**DANIEL—WELSH.**—On August 23rd, at All Saints', Ennismore Gardens, S.W., Augusta Moore Daniel, son of the late Edward M. Daniel L.R.C.S. (Ireland), and of Mrs. Daniel, Saxifield, Scarborough, to Margery Katherine, elder daughter of William Welsh, of Bifrons, Fleet, Hants.

**EDMONDS—FLOYD.**—On August 27th, at the Superintendent Registrar's Office, Westminster, Percy J. Edmonds, M.B., B.Sc., M.R.C.S., of 5 Great Marlborough Street, London, W., to Clara E. Edmonds, third daughter of the late William Floyd, of Weybridge.

**EWART—BERNEY.**—On August 24th, at St. Thomas's Church of England, Edinburgh, E. W. T. Ewart, M.B., eldest son of Lieut-Colonel Ewart, of Allerahaw, Lanarkshire, to Catherine Ann, youngest daughter of Sir Henry H. Berney, Bart., of Barton Bendish, Norfolk.

**GRIFFITH—ROBERTS.**—On August 23rd, at Llanystumdwy Church, Cardarvonshire, Idwal Griffith, Moria f Nevin, younger son of Samuel Griffith, M.D., J.P., of Portmadoc, to Lilian Gaynor, elder daughter of John Roberts, M.D., Talarvon, Cricieth.

## Deaths.

**CLARKE.**—On August 14th, at Villa Choisy, Interlaken, Switzerland, Thomas Clarke, M.D., in his 78th year.

**WHIDBORNE.**—On August 24th, at Warwick House, St David's, Exeter, Catherine S. W. Whidborne, widow of George Ferris Whidborne, M.D., ag d 81.

## Original Communications.

### THE PREVENTIVE TREATMENT OF SCARLET FEVER

BY ISOLATION (AGGREGATION) HOSPITALS.

By HUBERT E. J. BISS, M.A., M.D. Cantab., D.P.H.,  
Eastbourne;  
Late Assistant Medical Officer, Metropolitan Asylums Board.

#### PART II.

IN the last issue of THE MEDICAL PRESS AND CIRCULAR I spoke of the difficulty attending the diagnosis of the mild varieties of scarlet fever, and of how this fact seemed to me to be fatal to any consistent system for extirpating, or even largely reducing, the incidence of the disease by isolation. These mild cases occur even in the most severe epidemics, but with the change of form that scarlet fever has undergone during the last twenty-five or thirty years, they are much more frequently met with than formerly. Indeed, the whole character of scarlet fever to-day is so benign that it is a matter for consideration whether the disease is of sufficient moment to the community to warrant large expenditure of money to combat it. As I said earlier in this paper, scarlet fever was a dreaded, and justly dreaded, foe during the middle of the nineteenth century. Its reign was capricious, autocratic, and arbitrary, and its death-rate appalling. Independent of any human effort, however, it gradually changed its form, and before the aggregation hospital had been established as a recognised institution, it had become, like the scarlet fever of Sydenham's day, a disease in name only. There are, of course, still a proportion of severe and fatal cases, but the death-rate is now so low, some 3 per cent. on an average, that the importance of scarlet fever as an epidemic disease is greatly discounted. Measles and whooping-cough are far more dangerous and fatal, but the general opinion is that isolation is not worth trying as a means of controlling either of them; and with that opinion most people who are acquainted with these diseases, and have thought over the subject, will be disposed to agree. Supposing it be admitted that by the aggregation hospital system a certain proportion of attacks of scarlet fever are prevented, the question has to be faced as to whether it is a good investment of the money available for preventive medicine, to spend the enormous sums in sparing a few persons the trifling discomfort entailed by the disease in its modern form. For it must be remembered that by keeping up the present contributions a hundred and one useful sanitary measures are handicapped or rendered impracticable. The matter from this point of view has a commercial aspect that deserves careful attention. If the investment is justifiable, let it be retained; if it is not returning its value in security and relief to the population, let it be exchanged for some more profitable one. This scarlet fever expenditure is no small matter. In London three-fifths of the fever patients of the Metropolitan

Asylums Board are admitted for scarlet fever, and one may therefore reckon three-fifths of the Board's expenditure as incurred on account of that disease. Taking the year 1902 one finds that three-fifths of the fever hospital expenses amounted to no less than £222,000, and three-fifths of the fever ambulance service to £21,000. Without reckoning the proportionate part of the central office expenses, one arrives at the conclusion that scarlet fever aggregation costs London some quarter of a million pounds annually—the amount produced by a penny-halfpenny rate. If one turns to capital account and takes three-fifths of the amount sunk in fever hospital construction and equipment, one finds £1,333,000 incurred under this head, and £36,000 for capital expenditure on ambulance stations. In these figures I have not included the cost of Gore Farm Upper Hospital, which is frequently used for scarlet fever, nor the amount proposed to be spent on the new hospital of 800 beds at Carshalton. Here, again, one ought to add three-fifths of the capital expenditure on the central office, but leaving these items and interest on borrowed money out of account, the bill amounts to practically one and a half million pounds. It is difficult to escape from the reflection that a disease which causes only some five or six hundred deaths a year in London—deaths that would by no means be averted were the hospital service suspended to-morrow—is hardly worth so much expense. Without advocating unreservedly the use of these hospitals for the treatment of tuberculosis, I cannot but think that far greater relief would be accorded to suffering humanity if they were so employed. At the moment three-quarters at least of their accommodation is devoted to sustenance of healthy, able-bodied persons whose only sin against their fellows lies in the possession of a little shaggy skin on their hands and feet. If they were all let loose to-morrow there would probably be no rise in the scarlet fever notifications; the experiment has been tried elsewhere, and no adverse results followed.

When speaking of the records of epidemics of scarlet fever in the past, I referred to the constant confusion of that disease with other throat affections, especially diphtheria, and I ventured to express my impression that the two diseases often prevailed side by side. Nowadays, when we have a standard of reference for the diagnosis of that which we call diphtheria, we find that the old clinical distinctions are not of the value that they were once thought to be. If "diphtheria" gains in distinctiveness by the possession of its own bacillus, its borders are broadened to include a number of cases that have only that bacillus as their credential to the term. Nor is this all. Many a case that formerly gave the diagnostician no hesitation, no *arrière-pensée* of any kind, is now looked upon with a suspicion which can be dispelled only by the bacteriologist. A proportion of scarlet fever cases, varying according to circumstances, always contain Klebs-Löffler bacilli, in combination with other organisms, in the throat-exudation. Now, although these cases may present clinically no symptoms of diphtheria, they are potent to infect with the diphtheria organism, not only their neighbours in a ward or house, but even themselves at a later (convalescent) stage of their own illness. Consequently the scarlet fever wards of a hospital are seldom long

without diphtheria breaking out in them, and it is difficult to see how this can be avoided. Were all cases on admission subjected to bacteriological examination, and detained in wards separate from the other scarlet fever patients during their residence in hospital, it might be that post-scarlatinal diphtheria would become less frequent. But the administrative difficulties of arranging for such isolation are great, and till they are overcome it must be anticipated that scarlet fever patients will suffer from the evils of indiscriminate aggregation, and diphtheria be a common-place incident among scarlet fever convalescents. Aggregation of human beings is a non-rational device and always finds its reflection in disease outbreaks; this is true of every form of aggregation that has ever been brought about—camps, towns, schools, prisons, and what-not. Hospitals have shared this tendency in the past, and they continue to exhibit it even under modern regulation. Even in well-planned buildings in which every precaution that sanitary science can suggest is adopted, the mere accumulation of human beings under one roof has been shown to be essentially vicious. Thus, Dr. Sykes in his Milroy Lectures to the College of Physicians in 1901, speaking of the Peabody and Model buildings in St. Giles's, pointed out that whereas in these dwellings (which contain a good class of tenant, well supervised) the general and infant mortality is much below that of London generally, nevertheless the death-rate from certain infectious diseases is in excess—a result he attributed to nothing but the aggregation of numbers of people in a limited space.

Without amounting to alarming proportions post-scarlatinal diphtheria is still common enough to give cause for serious misgiving, though, happily, its mortality is enormously reduced by early diagnosis and serum treatment from what it was in pre-antitoxin days. If one takes the records of the last five-year period (1898-1902) of the Metropolitan Asylums Board Hospitals, one finds that 2,562 patients admitted for scarlet fever contracted diphtheria in hospital, and of these 105 died. Nor was this result accomplished by any particular epidemic; it was due to the day-in and day-out sequence of little groups of infections in different hospitals and different wards. The regularity of the appearance of diphtheria may to a certain extent be gauged by the yearly figures. Thus:

Year.	No. of Cases.	Deaths.	Mortality p.c.
1898	661	24	3'6
1899	692	25	3'6
1900	405	12	2'96
1901	380	23	6'05
1902	424	21	4'95

Here it will be seen that except for slight fluctuations the average of post-scarlatinal diphtheria was well maintained in each year, and it seems likely to continue to be so under prevailing conditions. Thinking that diphtheria infection of scarlet fever patients was perhaps the result of receiving patients suffering from the two diseases into the same hospitals, the managers of the Metropolitan Asylums Board arranged in 1901 to use for their separate treatment two neighbouring hospitals—the Grove and the Fountain—the former being reserved for diphtheria, the latter for scarlet fever. One year's experience sufficed to show that this method was not of any avail for the purpose, and the old arrangement was consequently reverted to. Not only is diphtheria a constant occurrence in scarlet fever wards, but scarlet fever is equally a feature of diphtheria wards, and though figures under this head are not available for citation, I should give it as my general impression that post-diphtheritic scarlet fever is about as common as post-scarlatinal diphtheria. It may safely be said, at any rate, that scarlet fever is a very usual feature of diphtheria wards. But scarlet fever in diphtheria wards and diphtheria in scarlet fever wards are not the only banes of the fever medical officer's life, for measles, whooping-cough, rōtheln, and chicken-pox are daily events, and frequently two or more of these maladies occur synchronously. The number of beds available for hospital purposes is practically always gravely curtailed by various wards being placed

*hors de combat* from outbreaks of one or other of these diseases, and it is idle to say that such occurrences are not a serious blot on the efficiency of the institutions, not to mention the opprobrium they bring on the administration. A fever hospital has been wittily described as "a place where you go in with one disease and catch all the others." Like most epigrammatic sayings, this is more *ben trovato* than exact, but it contains a germ of truth. Under present circumstances, and without enormously increasing the expenditure on these hospitals, I fail to see how things are to be otherwise.

Another danger of the fever hospital—likewise to a great extent unavoidable—is that of wrong primary diagnosis of the disease from which the patient is suffering. If protection is to be afforded by the hospital, prompt and early removal of the patient is essential to success. Medicine, however, does not lend sufficient aid to its followers to ensure this being always done, and one is not surprised that a large number of patients are annually sent in certified to be suffering from scarlet fever who, in fact, are not. During the same five-year period (1898-1902) that I have before referred to, I find that into the Metropolitan Asylums Board Hospital, 3,118 persons were admitted for scarlet fever who were the subject of other maladies. The proportion they bore to the total admissions was as follows:—1898, 4'7 per cent.; 1899, 3'9 per cent.; 1900, 5'8 per cent.; 1901, 5'9 per cent.; 1902, 4'8 per cent. It is one thing to say that a person has scarlet fever, but quite another thing to say that he certainly has not, so that in practice the usual course is to retain patients so certified till the diagnosis can be confirmed or refuted. Thus many persons are detained in hospital for a fortnight or three weeks, and as isolation accommodation is not always available, a certain number of them disprove the original diagnosis by catching scarlet fever while under observation. For a reduction of these mistaken primary diagnoses one cannot look. If scarlet fever is to be dealt with vigorously under any isolation plan, it will become necessary to certify and remove on suspicion a vastly larger proportion of doubtful cases than at present. Little as one may like the prospect, I can see no alternative if this preventive measure is to be thoroughly tried and pushed to its logical conclusion.

But even if all these difficulties and disabilities could be removed, there remains one further circumstance which, like the fly in the 'pothecary's ointment, is like to spoil the whole of the roseate scheme. This mild disease has proved hitherto as little susceptible to the wooings of the clinician as to the big guns of the municipal sanitary department. It is neither charmed by the one nor frightened by the other. Like a coy girl, scarlet fever grudgingly reveals its secrets to those who pay it attention, and only those whose information is derived solely from text-books can think they have any knowledge of the vagaries of the disease. It must have been supposed by those responsible for inaugurating the aggregation hospital that scarlet fever was an acute infectious disease that ran a fairly definite course, and left the patient at the end of a fixed period free to mingle with his fellow-men without endangering their health by his proximity. If there is one thing that the aggregation hospital has done, it has been to demonstrate its own ineptitude as a safeguard against scarlatinal infection. Clinical knowledge of scarlet fever has been wrung little by little from studying the disease at close quarters under hospital conditions, and, though it be not yet generally admitted, there can now, I think, be no reasonable doubt that the lengthened infectivity of scarlet fever is due to certain local lesions produced by the disease tending to run a subacute or chronic course in certain constitutions. The chief of the lesions are inflammations affecting the pharynx, nasopharynx, ear and nose. The class of case in which these events occur must surely have been overlooked by the founders of the hospital system, for it invalidates and renders nugatory no inconsiderable proportion of the benefit that might otherwise accrue to the community from the preventive influence of the system.

Inflammatory lesions of the pharynx in scarlet fever are almost invariably characterised by a persistence that contrasts markedly with the course of like lesions in diphtheria. A few days after even a severe attack of diphtheria will generally find a patient's throat-tissues pale, not swollen, clean and white. With scarlet fever, even if ulceration does not occur, nearly always one finds the throat reddened for a long time, the tissues more or less œdematous, the submaxillary lymph glands hard and knotty. A similar intensity marks inflammations of the naso-pharynx and nasal tissues when these are affected, and the otitis media of the disease is usually a persistent one. Moreover, for a long time after apparent convalescence, any slight chill or similar adverse circumstance is apt to convert these subacute conditions into active ones, and recrudescence of the pharyngitis, rhinitis, or otitis media results. Especially in children with hypertrophy of the adenoid tissues of the naso-pharynx and obstruction to the free passage of air through the nose, does this happen. These inflammatory lesions of the upper air passages may directly follow the primary attacks of scarlet fever, or they may remain quiescent for a long time. Frequently they subside; not infrequently they persist. The subjects of these manifestations suffer at intervals from tonsillitis or pharyngitis; submaxillary lymph-adenitis, leading perhaps to abscess; chronic otitis media, with, sometimes, infection of the cells of the temporal bone, lateral sinus or brain; chronic rhinitis with nasal discharge. The more serious of these affections naturally detain the patient in hospital till death or cure release him, but a quiescent otitis media or rhinitis, offering as they both do no external sign of their presence, allow many a patient to be sent home in a potentially infectious state. It is impossible to attribute blame to the medical officer. So common are these chronic lesions that if one waited till all sign of inflammatory trouble had disappeared from throat, nose, and ear, a good half of the patients would be detained for many months. Practically this is impossible, and the rule is to send home those cases which do not exhibit, after a period of weeks, any sign of active disease. The general result is that the conditions gradually disappear, but unfortunately this is not always so. Some tangible or intangible influence resuscitates the lurking poison, and discharge from the nose or ear appears from the revived inflammation; the child is then at least as infectious as he was on the day he came to hospital. Every fever hospital has its "return" cases, as they are called, no matter how careful its administration. No one can tell which of a hundred discharged cases will prove to be infectious afterwards, but one knows that three, four, or five of them will infect their relations or playfellows, sooner or later. In fact, as a medium for disseminating scarlet fever, it is difficult to conceive of anything more appropriate than a healthy youngster, who has no worse trouble than a running nose, attending school, gambolling with his mates, and daubing their toys with the secretions of his infected nasal mucous membranes. Mere retention of these cases with chronic lesions of the upper air passages in hospital does not suffice to emasculate the infection; one patient of the Metropolitan Asylums Board was kept for eight months on account of a nasal discharge, but returning home, apparently cured, he conveyed scarlet fever to his brothers and sisters. Various devices—none very promising, perhaps—have been resorted to to obviate the slur which the return case is supposed to cast on hospital administration, but so far none have achieved even a modicum of success. The liability to discharge cases that prove afterwards to be infectious lies in the facts that scarlet fever is a disease with subacute and chronic tendencies; that we have but poor means of diagnosing in which case these tendencies will be displayed; and that the hospital system is impotent to provide means to control them. There is one minor reform that might accomplish some good: I mean abandonment of the traditional practice of giving children a hot bath immediately before sending them out of the hospital gates. Any measure better calculated to stir into activity the smouldering inflammations in the upper respiratory passage it is hard to imagine.

But this really is a side issue; the whole question is far deeper and broader and more far-reaching. The point is that the hospital system and clinical knowledge and methods are inadequate to cope with the demands made on their resources by scarlet fever, and that while return cases continue in fair abundance one cannot regard the hospital—apart from every other objection—as fulfilling a function of much service to the community. When we add to this disability the positive evils resulting from aggregation, the lack of any diminution in the mortality and prevalence of the disease, the mistakes—unavoidable mistakes, if isolation is to continue—in certification, and the inability of medical science to distinguish mild cases of scarlet fever, and to sift single infections from complicated ones, we are driven to the conclusion that the present system is but ill-adapted to the end for which it was designed. With these grave faults and shortcomings, is it worth while continuing the enormous expenditure on our aggregation hospitals? Is it worth while, in any case, when scarlet fever is now so benign in its incidence that 80 per cent. of its victims are but little more than out of sorts for a few days? These questions deserve, I think, serious consideration, and if they are kept at the level of scientific reasoning that their interest and importance entitle them to, they are ripe for free discussion among sanitarians. I trust they may be preserved from the hurly-burly of municipal politics with which they have no primary concern, and that a full and authoritative inquiry under medical auspices may be instituted to resolve them.

### THE EARLY MANIFESTATIONS OF INSULAR SCLEROSIS,

WITH A TABLE SHOWING THE MODES OF ONSET IN FIFTY CASES, TAKEN FROM NOTES MADE AT THE NATIONAL HOSPITAL, IN QUEEN SQUARE, BY THE KIND PERMISSION OF THE MEDICAL STAFF.

By FREDERICK S. PALMER, M.D., M.R.C.P.,  
Assistant Physician to the West End Hospital for Diseases of the Nervous System.

IN the seventh of Charcot's classical lectures delivered at La Salpêtrière in 1858, portraying the disease, justly designated disseminated or multilocular sclerosis, he maintained that "nothing is simpler than to diagnose the affection in question by the bedside of the patient, at least when it has reached its typical period of perfect development."

The paragraph read according to its literal construction is probably not far from the truth. The clinical tableau so accurately sketched by the distinguished French neurologist remains after an interval of thirty-six years a faithful representation of what is known as the classical type. Nor would it be easy, in confrontation of such complete evolution of the symptomatology as he described, to mistake its significance. It did not, however, escape Charcot's notice that the disease may be encountered under a variety of masks—in all sorts of disguises—and that in these aberrant or imperfect forms the recognition of the primary indicia is by no means a simple proceeding. That these atypical varieties undoubtedly exist, and are not of very rare occurrence, constituting the class known as *formes frustes*, is now commonly admitted. Such cases not infrequently run a protracted course of years from start to finish, presenting few of the salient features of the typical disease until an advanced stage has been reached, and sometimes (though more rarely) none that can be called absolutely characteristic. The importance of recognising the manifestations of these irregular types has been strongly insisted on by Dr. Buzzard, who, from long experience and careful study of the subject, has made it in a peculiar sense his own. It is impossible to question the accuracy of his assertion, "that of all organic diseases of the nervous system, disseminated sclerosis is that which is commonly mistaken for hysteria."

The polymorphic nature of the malady, its variable periods of remission or intermission, and the frequent

association of emotional symptoms often render the differential diagnosis a task of considerable difficulty in the absence of pronounced hysterical stigmata. It is true that much has been done recently to unravel some of the complicated problems which these atypical cases present, but there remains still a large field for clinical investigation. Presumably, as our knowledge of neuro-pathology increases, and, it may be, as Dr. Ashley Mackintosh has suggested, by the adoption of more liberal views concerning the accepted cardinal signs, many conditions regarded as examples of psychoneurosis due to disturbance of the highest nervous centres will be referred to the initial stages of insular sclerosis.

In reviewing the multiformity and irregularity of the primary manifestations, it is indispensable to remember the anatomical lesions which constitute the malady; nor is it less important to bear in mind the fact, insisted on by Dr. J. S. Risien Russell, that from the standpoint of the nervous system the disease is, as a rule, a general one, affecting the whole of the cerebro-spinal axis from the cerebral cortex to the filum terminale, involving the ganglia, cranial and spinal nerves with their roots, and invading their peripheral branches. The sclerotic islets obey no fixed law, either in development or distribution; hence departures from the typical form are not uncommon. No two cases can be said to resemble each other exactly in their modes of onset or progress. As all parts of the nervous mechanism are open to attack, it is not difficult to understand the first blow of the disease will fall upon the locality which the morbid process has selected. The division of the malady into three recognised types, distinguished by Charcot and followed by nearly all the other writers on the subject, is, as Marie remarks in his tenth lecture, merely an artificial arrangement employed for the convenience of description, and the terms cephalic, spinal, and mixed or cerebro-spinal apply chiefly to the character of the predominating symptoms. Anatomically there is no such limitation to the morbid process. The four types constructed by Marie, based on the modes of onset and rate of progress, need not detain us; many, if not the majority, of chronic nervous diseases could be similarly subdivided. Far more important than any distinction of types seems to be a clear understanding that in insular sclerosis many departures are seen from the classical forms described by Charcot, and that the disease has remarkable periods of remission.

During the twelve months I acted as clinical clerk to Dr. Ferrier at the National Hospital, and had the advantage of his teaching, several examples of irregular type came under my notice. At his suggestion, with the kind permission of the medical staff, whose invariable courtesy I desire gratefully to acknowledge, and with the assistance of the house physicians, I have collected notes of the early manifestations in fifty cases recently under treatment in the wards, arranged in the form of a table, which may be considered a sequel to the interesting article of Dr. Mackintosh in the "Review of Neurology and Psychiatry" for February, 1903. From an analysis of the Table the following results are obtained:—

*Sex.*—There were 23 males and 27 females, which agrees with the view of Marie and others that in this disease the sexes are equally affected.

*Age.*—The incidence of age at the time of admission to the hospital is given in the decennial periods below—

Between 10—20	20—30	30—40	40—50	50—60
2	14	26	6	2 = 50

From these figures, the interval between the commencement of the symptoms to the date of admission must be subtracted. In the main the facts are in accordance with the experience of all neurological writers, that the majority of the cases occur in early adult life. The disease is rarely seen in children or after fifty years of age.

*Condition.*—In the 50 cases, 27 were married and 23 single.

*Occupation.*—The only circumstance worth recording is that 23 of the patients (nearly half) were engaged in domestic pursuits. There was nothing that could be

traced to the influence of toxic agents from certain trade occupations insisted on by Oppenheim.

*Causation.*—Although no definite cause could be discovered in the majority of the cases, it is interesting to note that the symptoms commenced either during pregnancy or soon after delivery in 6, after trauma in 5, after epidemic influenza in 5, after diphtheria 1, after sore throat (variety not known) 1, and in one case the patient referred his illness to a severe attack of gonorrhoea, which he said preyed on his mind to a great extent. Emotional causes were suggested in four of the cases, but these did not appear to be very definite. Sir William Gowers has called attention to the connection between disseminated sclerosis and the puerperium, beginning during pregnancy, remaining in abeyance until the next, and then becoming progressive. In the other cases the condition could not be traced to any antecedent illness or other known cause of the disease.

*Duration.*—In this calculation care was taken to ascertain as nearly as possible the actual time when nervous instability first appeared in a definite form. The result, taken from the statements of the patients, is given below.

Under 1 year, 6;	between 1 and 2 years, 11;	2 and 3 years, 3;	3 and 4 years, 7;	4 and 5 years, 9;	6 years 3;	7 years, 3;	8 years, 4;	9 years, 1;	10 years, 1;	13 years, 1;	14 years, 1=50.
------------------	----------------------------	-------------------	-------------------	-------------------	------------	-------------	-------------	-------------	--------------	--------------	-----------------

The longest period was 14 years, and the shortest about a month. The cases deserving of comment from their long duration are numbers 42, 5, 22, and 31 recorded in the Table.

In Case 42, the illness commenced with tenderness of the plantar surface of both feet, followed by difficulty in walking. At first the motor weakness was transient or intermittent in character. After a few months the disability became more pronounced, but although he had experienced several periods of partial remission, the paresis had been steadily progressive.

In Case 5, the patient first noticed difficulty in walking with staggering and girdle pain round the waist during her first pregnancy. After her confinement, she appeared to recover the power of walking completely, but three months later the same symptoms returned. She had four similar attacks subsequently with partial recovery on each occasion. For the last two years her gait has been so unsteady that she has never ventured out alone.

In Case 22, the primary symptom observed was weakness of the right leg and stumbling. Her right foot seemed to strike against any object higher than the surface. After treatment in the National Hospital she improved a good deal, but always noticed some degree of weakness in the same foot. She was, however, able to nurse her husband through a long illness, and after his death supported herself by her own industry. Subsequently her right arm and hand became affected.

In Case 31, a labourer first experienced difficulty in rising from his chair with staggering on attempting to walk. The symptoms were not at first continuous, but lasted several months at a time. He had tried several occupations, but had to give them all up one after another on account of his illness, and for the last seven months he has been unable to walk without assistance.

In Dr. Buzzard's interesting lecture on Insular Sclerosis, delivered at the National Hospital on February 9th, he described the details of four cases under his care which had existed with varying periods of remissions, two for 13 years, and the other two for 8 and 9 years respectively.

*Onset.*—The onset was sudden in 12 of the cases, and marked by a gradual invasion in 38.

The number of the former is relatively high compared with Dr. Mackintosh's series, 24 against 12½ per cent.

In the arrangement of the Table, the first symptom mentioned is that which the patients gave, as the earliest indication of their nervous disease. Divided into groups according to the usual classification the result obtained is—

TABLE REPRESENTING THE MODES OF ONSET IN FIFTY CASES OF MULTIPLE SCLEROSIS.

No.	Sex, Age, Condition.	Occupation.	Interval from Onset.	Onset: S. Sudden. G. Gradual.	Primary Indications of Nervous Instability.	Gait.	Deep Tendon Reflexes.	Plantar Reflexes.	Sphincters.	Cardinal Symptom
1	M 40 M	Clothier	3 yrs	S	Apoplectiform attack followed by stiffness of legs	Spastic	Exag. ankle clonus	Extensor	Precip. mict.	Nystag., vol. tremor, some dysarthria.
2	M 21 S	Porter	14 mos.	G	Unsteadiness of gait, fatigue in walking	Reeling and tottering	Exag. ankle clonus	Extensor	Precip. mict., inconst. constip.	Int. and head trem., blurred speech, pallor of opt. discs.
3	M 32 S	Blacksmith	4½ yrs.	G	Vomiting for 7 days followed by dysarthria	Ataxic	Exag. ankle clonus	Extensor	Precip. mict. constip.	Vol. tremor, scanning speech.
4	M 26 S	Hostler	18 mos.	G	Giddiness, staggering, sacral pain, amblyopia (transient)	Ataxic and staggering	Exag. ankle clonus	Extensor	Hesitating mict.	Nystag., vol. tremor, syllabic speech.
5	F 50 M	Domestic	13 yrs.	G	Difficulty in walking, staggering, girdle pain	Spastic and dragging	Exaggerated	Extensor	Precip. mict.	Nystag. vol. tremor.
6	F 20 S	Vocalist	3 yrs.	S	Headache, giddiness, transient amblyopia	Spastic and dragging	Exag. ankle clonus	Extensor	Normal	Nystag., pallor of opt. disc.
7	F 35 M	Domestic	5 yrs.	S	Diplopia with loss of power in R. leg	Spastic and staggering	Exaggerated	Extensor	Some inconst.	Vol. tremor R. arm and leg.
8	M 29 M	Hawker	6 yrs.	G	Difficulty in lifting R. foot, staggering	Ataxic and reeling	Exaggerated	Extensor	Inconst. of urine and faeces	Nystag., slow scanning speech.
9	F 21 S	Domestic	6 yrs.	G	L. leg gave way in walking, 3 epileptiform attacks	Spastic slightly	Exaggerated	Extensor	Some inconst. of urine	Nystag., scanning speech, opt. atrophy.
10	F 36 M	Domestic	5 yrs.	G	Weakness of L. arm and leg during pregnancy	Unable to stand	Exag. ankle clonus R. side	Extensor	Inconst. and retention of urine.	Pallor of opt. discs.
11	M 41 M	Chemist	18 mos.	G	Stiffness and fatigue in legs, chiefly left	Spastic and tottering	Exag. ankle clonus	Extensor	Precip. mict.	Nystag., syll. speech, L. opt. atrophy.
12	M 30 S	Clerk	1 yr.	S	Dysarthria, weakness of legs, giddiness	Unable to stand	Exag. ankle clonus	Extensor	Loss of control over blad. & rect.	Nystag., vol. tremor, syllabic speech.
13	M 37 M	Clerk	5 yrs.	S	Loss of power in legs, diplopia, inconst. of urine	Spastic and ataxic	Exag. ankle clonus R. side	Extensor	Diff. in starting mict.	Nystag. on upward movement.
14	F 38 M	Domestic	8 yrs.	G	Weakness of the legs, chiefly of the left	Unable to stand	Exag. ankle and knee clonus	Extensor	Normal	Nystag., vol. tremor, opt. atrophy.
15	M 28 M	Surveyor	2 yrs.	G	Dragging of R. leg, difficulty and delay in mict.	Ataxic and staggering	Exaggerated	Extensor	Difficulty in starting mict.	Nystag. on lateral deviation.
16	F 36 M	Domestic	5 yrs.	G	Weakness of L. leg during pregnancy, inconst. of urine.	Hemiplegic	Exag. ankle clonus R. side	Extensor	Inconst. of urine	Syllabic speech.
17	M 37 M	Labourer	2 yrs.	G	Weakness of L. leg after a fall	Ataxic	Exag. ankle clonus L. side	Extensor	Inconst. of urine and faeces	Nystag., slowness of speech.
18	F 32 M	Domestic	6 yrs.	S	Fatigue in R. leg, staggering, numbness of L. leg and inconst. of urine	Spastic and dragging	Exag. ankle clonus	Extensor	Precip. mict. and inconst. of faeces	Some int. tremor.
19	M 37 M	Omnibus writer	4 yrs.	G	Dragging of R. foot in walking	Unable to stand	Normal	Extensor R. side	Precip. mict.	Nystag. on lateral deviation, pallor of opt. discs.
20	M 32 S	Pianoforte worker	8 yrs.	G	Staggering gait, fatigue in walking	Unable to stand	Exag. ankle clonus	Extensor	Precip. mict.	Nystag. on lateral deviation.
21	F 20 S	Domestic	7 yrs.	G	Numbness and tingling of L. foot, dragging	Spastic and shuffling	Exag. ankle and knee clonus	Extensor	Inconst. of urine	Nystag. pallor of L. optic disc.
22	F 45 W	Domestic	10 yrs.	G	Dragging of R. foot, stumbling	Dragging and shuffling	Exag. ankle clonus R. side	Extensor	Normal	Slight nystagmoid movements on lateral deviation.
23	F 35 S	Domestic	3 yrs.	G	L. leg gave way in walking, followed by weakness of both legs	Spastic and dragging	Exag. ankle clonus	Extensor	Precip. mict.	Vol. tremor, opt. atrophy.
24	F 32 M	Domestic	3½ yrs.	G	Weakness of legs in walking, stumbling	Spastic, cannot walk	Exag. ankle clonus	Extensor	Inconst. of urine	Nystag. volitional tremor.
25	F 55 M	Domestic	4 yrs.	G	Stiffness of R. leg, sacral pain	Dragging, slightly spastic.	Exaggerated	Extensor	Inconst. of urine and faeces	Nystag. (fine oscillations).
26	M 46 M	Labourer	5 yrs.	G	Pain in sacral region, followed by staggering.	Shuffling, cannot walk	Exag. ankle clonus	Extensor R. side	Inconst. of urine	Nystag. syllabic speech, opt. atrophy, vol. tremor.
27	F 34 S	Charwoman	2 yrs.	G	Numbness in L. leg, difficulty in walking	Spastic dragging of L. leg	Exag. ankle and knee clonus	Extensor L. side	Normal	Nystag. in all directions.
28	F 36 S	Housekeeper	3 yrs.	G	Trembling of R. hand, inability to write	Spastic and reeling	Knee-jerks brisk	Extensor	Normal	Nystag. vol. tremor.
29	F 27 S	Packing-case maker	3 mos.	G	Numbness of both feet diff. in walking, staggering	Ataxic slightly	Knee-jerks brisk	Indefinite inconst. to ext.	Normal	Nystag., vol. tremor, l. arm.
30	M 33 M	Warehouseman	5 mos.	S	Stumbling of R. foot, trembling and weakness in both legs	Unable to walk	Exag. ankle and knee clonus	Extensor	Retention, constipation	Nystag. on lateral deviation.
31	M 30 M	Labourer	9 yrs.	G	Difficulty in rising from chair, staggering	Ataxic and reeling	Normal jaw-jerk present	Extensor	Normal	Nystag., vol. tremor, syllabic speech.
32	F 28 S	Domestic	8 yrs.	G	Numbness and weakness in both legs	Spastic dragging	Brisk ankle clonus L. side	Extensor	Delay in mict. constipation	Nystag., vol. tremor R. arm, pallor of R. opt. disc.
33	F 19 S	Domestic	4 yrs.	S	Giddiness, diplopia, numbness of three fingers R. hand	Dragging of L. leg	Brisk	Extensor L. side	Normal	Nystag. (fine oscillations).
34	M 28 M	Stableman	7 yrs.	S	Numbness, followed by weakness of both legs	Spastic and dragging	Brisk ankle clonus on R. side	Extensor	Precip. mict.	Nystag. syll. speech, opt. atrophy.
35	M 29 M	French polisher	2 yrs.	G	Dysarthria, diplopia, weakness and numbness of R. leg.	Ataxic and slightly spastic	Brisk ankle clonus on R. side	Extensor R. side	Precip. mict. constipation	Nystag., vol. tremor, syllabic speech.
36	F 26 S	Domestic	2 yrs.	G	Weakness of L. leg with dragging of foot	Unable to stand	Brisk ankle clonus	Extensor	Inconst. of urine	Vol. tremor.
37	F 24 S	Domestic	2 yrs.	S	R. facial paralysis, dysarthria and numbness of R. leg	Ataxic. ten. to fall to R. side	Brisk knee clon.	Extensor R. side	Normal	Nystag. on upward and lateral deviation.
38	M 34 M	Labourer	4 yrs.	G	Shaking of R. hand, fatigue in walking, staggering	Spastic and staggering	Brisk ankle clonus	Extensor	Diff. in starting mict. and constipation	Nystag. vol. tremor, staccato speech, pallor of opt. disc.

No.	Sex, Age, Condition.	Occupation.	Interval from Onset.	Onset: S. Sudden, G. Gradual.	Primary Indications of Nervous Instability.	Gait.	Deep Tendon Reflexes.	Plantar Reflexes.	Sphincters.	Cardinal Symptoms.
39	M 35 M	Stableman	4 yrs.	G	Trembling and dragging of L. foot in walking	Ataxic and spastic	Brisk ankle clonus	Extensor	Diff. in starting mict. and constipation	Nystag., pallor of R. opt. disc.
40	M 30 M	Butler	5 yrs.	G	Unsteadiness of gait, staggering	Staggering, dragging of L. foot	Brisk ankle clonus R. side	Extensor	Diff. in starting mict. and constipation	Nystag., pallor of opt. discs.
41	M 37 S	Engine driver	18 mos.	G	Diff. in lifting feet from the ground, chiefly left	Spastic	Brisk ankle clonus L. side	Extensor	Incont. of urine	Nystag., vol. tremor, slow syllabic speech.
42	M 35 S	Labourer	14 yrs.	G	Tenderness of both feet, increasing difficulty in walking	Spastic titubation	Brisk ankle clonus	Extensor	Normal	Scanning speech, vol. tremor, opt. atrophy.
43	F 15 S	None	6 mos.	S	Vomiting for 7 days, followed by weakness of legs	Unable stand	Brisk ankle clonus	Extensor	Precip. mict.	Nystag., vol. tremor.
44	F 45 M	Domestic	5 yrs.	G	Weakness of legs and staggering	Spastic and ataxic	Brisk ankle clonus	Extensor	Diff. in starting mict.	Nystag., vol. tremor, syllabic speech.
45	F 35 S	Domestic	4 1/2 yrs.	G	Scraping of L. leg. in walking, staggering	Unable stand	Brisk ankle clonus	Extensor	Precip. mict.	Nystag., vol. tremor, syllabic speech.
46	F 31 S	Domestic	7 yrs.	G	Unsteadiness in both hands, diff. in walking	Reel and staggering	Brisk ankle clonus	Extensor	Precip. mict.	Nystag., vol. tremor, syllabic speech.
47	F 47 S	Milliner	1 mo.	S	Numbness of left side, diff. in walking, diplopia	Tottering	Exaggerated	Extensor L. side	Incont. of urine	Nystag., vol. tremor.
48	F 38 M	Domestic	8 yrs.	G	Numbness of R. leg following abortion	Unable stand	Exaggerated	Extensor	Precip. mict.	Nystag.
49	F 30 S	Hospital nurse	4 yrs.	G	Loss of sensation in R. arm and numbness in both legs	Unable stand	Exaggerated	Extensor	Some incont. of urine	Nystag., vol. tremor, staccato speech.
50	M 25 M	Roadsweeper	8 mos.	G	Fatigue of L. leg, vertigo, staggering	Ataxic	Normal	Extensor	Some incont. of urine	Nystag., vol. tremor, syllabic speech, opt. atrophy.

- A—with cerebral or bulbar symptoms leading .. .. . 10
- B—with motor and sensory (combined) symptoms leading .. .. . 9
- C—with motor symptoms leading .. .. . 26
- D—with sensory symptoms leading .. .. . 5

It will be noticed that onset with motor weakness was observed in more than half the number of the cases, or at the rate of 52 per cent.

In the cerebral and bulbar group (A) are included—

- Onset with apoplectiform attack .. .. . 1
- Vomiting .. .. . 2
- Vertigo .. .. . 2
- Diplopia .. .. . 1
- Dysarthria .. .. . 1
- Dysarthria and diplopia .. .. . 1
- Headache (occipital) .. .. . 1
- Facial paralysis .. .. . 1

In the motor and sensory group (combined) (B)—

- Onset with numbness and weakness of both lower limbs .. .. . 2
- Numbness and weakness of one lower limb .. .. . 3
- Weakness of both legs and girdle pain .. .. . 1
- Weakness of both legs and numbness of one arm .. .. . 1
- Numbness and weakness of one arm and leg .. .. . 2

In the motor group (C)—

- Onset with weakness of both lower limbs .. .. . 0
- Weakness of one lower limb .. .. . 13
- Weakness of both upper limbs .. .. . 7
- Weakness of one upper limb .. .. . 2
- Weakness of one arm and leg (hemiparesis) .. .. . 1

- In the sensory group (D) —
- Onset with numbness followed by weakness of both lower limbs .. .. . 1
- Numbness of one leg after abortion .. .. . 1
- Tenderness of both feet, followed by progressive paresis of legs .. .. . 1
- Anæsthesia of right arm followed by numbness of both legs .. .. . 1
- Pain in sacral region, followed by staggering gait .. .. . 1

Remissions of the symptoms occurred in 26 of the cases, or at the rate of 52 per cent. In this estimate every admission of apparent improvement has been taken into consideration. The intervals and degrees of recovery were most variable, from slight amelioration to almost complete intermission, but in none of the cases did all the symptoms entirely disappear. Some amount of motor weakness or paresthesia remained. In one of the cases there were four remissions, in another three. Two remissions were described in eight, and one each in sixteen of the cases.

**Gait.**—At the time of admission to the hospital the various forms of gait noticed were, cerebello-spastic, 21, ataxic, 9; spastic and ataxic, 4; hemiplegic, 1; tottering, shuffling, and dragging, 4; unable to stand or walk, 11 = 50.

These figures agree with the text-books, that although almost every variety of gait is said to occur, the cerebello-spastic is the one most frequently encountered.

**Tendon Reflexes.**—The knee-jerks were brisk or exaggerated in 47 and normal in three, but the jaw-jerk was definitely obtained in one of the latter. Ankle-clonus was marked in 22 on both sides, in 12 on one side, and knee-clonus was present in 5 of the cases.

**Plantar Reflexes.**—Babinski's phenomenon was present in 41 of the cases on both sides, and in eight on one side only. In the other, the response was indefinite, but inclining to the extensor type.

**Sphincters.**—The organic reflexes were affected in 40 and normal in 10, but in the latter number one of the patients had suffered from incontinence of urine before admission, and had recovered control. The details given were as follows:—Precipitate micturition, 16

hesitating micturition, 8; incontinence of urine, 11; incontinence of urine and feces, 4; retention of urine and constipation, 1. In a large number of the cases the sphincter affection was a comparatively early feature of the disease.

*Accepted Cardinal Signs.*—The inconstancy of the so-called classical symptoms is illustrated by the figures given below:—

In the 50 cases now recorded—

Nystagmus, volitional tremor, and speech defects were observed in .. .. .	12
Nystagmus and volitional tremor in .. .. .	10
Nystagmus and speech defects in .. .. .	5
Nystagmus, or nystagmoid movements alone, in ..	14
Volitional tremor and speech defects in .. .. .	3
Volitional tremor alone in .. .. .	4
Speech defects alone in .. .. .	1
Pallor of optic discs alone in .. .. .	1

It will be noticed from these figures that nystagmus, or nystagmoid oscillations (chiefly on lateral deviation), were present in 41 of the cases, or at the rate of 82 per cent., and were the most constant of the so-called classical signs. The rate appears high compared with Charcot's estimate of 50, Uhtoff's of 58, and Marie's of 70 per cent., but in the present series the finer movements have been included. Volitional tremor and speech defects were observed in 21, or 42 per cent. According to Sachs all forms of dysarthria are seen, from what he described as "a speech tremor not unlike that observed in the early stages of general paralysis" to the ordinary scanning, staccato, or syllabic utterance. I have therefore grouped all forms of abnormal articulation under this head. In one of the cases pallor of the temporal halves of the optic discs was the only classical sign present.

Changes in the fundus oculi were noticed in 13 cases, at the rate of 26 per cent.

Optic atrophy on both sides .. .. .	7
Optic atrophy on one side .. .. .	1
Pallor of both discs (temporal halves) .. .. .	4
Pallor of one disc (temporal half) .. .. .	1

There is great variation in the figures given by the different writers on these changes. Those quoted by Ross are at the rate of 30, Buzzard 43, Uhtoff 45, and Mackintosh 47.5 per cent.

Uhtoff found complete optic atrophy in only 3 of the 100 cases on which he based his observations.

*Facies.*—The peculiar facies mentioned by Charcot—a certain vagueness of expression or stolid indifference to present surroundings, with some degree of mental enfeeblement, were noticeable in 17 of the cases.

*Sensory Symptoms.*—The researches of Hoffman, Erb, Freund, F. von Gebhardt, Oppenheim, and others have proved beyond all dispute that disturbances of common sensibility are of very frequent occurrence in disseminated sclerosis. Charcot qualified his remark, that they do not form a part of the clinical picture, by the admission "that formication and numbness in the enfeebled limbs of a transient nature were sometimes complained of." With the exception of the Babinski phenomenon they were probably the most constant of all the symptoms in the present series of cases. Thus, in the 50 now recorded no less than 42 referred to some kind of sensory disturbance (chiefly subjective in character) as a part of their illness, and in 8 only were the sensations perfectly normal. The paræsthesiæ comprised headache, pain over the sacral region, girdle sensations, cramp, numbness, tingling, and a feeling of what was described as deadness in the affected members. Objective symptoms were noticed in 7—analgesia, hyperalgesia, anæsthesia, and loss of muscle sense. In two of the cases trophic changes were observed—atrophy of limited groups of muscles. In 100 cases of insular sclerosis quoted by Hoffman, he found paræsthesiæ in 66 and objective sensory symptoms in 28, or together at the rate of 94 per cent., which correspond very closely with my figures. These observations support Dr. Mackintosh's view that disturbances of sensation are valuable aids to diagnosis in insular sclerosis.

*Conclusions.*—The inferences to be drawn from a study of the preceding notes are, I venture to think—

1. That the primary indicia of multilocular sclerosis are exceedingly variable both in distribution and degree.
2. The onset may be either gradual or sudden in character.
3. The most common mode of onset is with motor weakness of the lower limbs, more frequently at first limited to one leg; but that onset with cerebral, bulbar, or sensory symptoms forms a considerable proportion of the cases.
4. Pregnancy and the puerperal state, trauma, and the acute infections are not infrequent antecedents.
5. Remissions and intermissions of the symptoms of variable grades, and for indefinite periods, occur in a large number of the cases.
6. Many varieties of gait are observed in the disease, but the most common is the cerebello-spastic type.
7. The Babinski phenomenon is the most trustworthy and constant of all the symptoms.
8. The tendon reflexes are, as a rule, exaggerated, but in a certain number of the cases may be normal.
9. The organic reflexes are usually affected, and constitute an early feature of the disease.
10. Sensory symptoms (chiefly paræsthesiæ) are commonly complained of, either early or during the progress of the malady, and are of considerable diagnostic value.
11. Emotional symptoms, the peculiar facies, and some degree of mental enfeeblement (loss of memory) are not infrequently observed.
12. Of the so-called classical signs, nystagmus or the finer nystagmoid oscillations are the most frequent. Volitional tremor and defects of articulation are less commonly seen.
13. Optic atrophy and pallor of the optic discs are very frequent but variable symptoms.

## THE DYSPEPTIC ORIGIN OF THE MINOR SYMPTOMS OF BRIGHT'S DISEASE.

By DR. N. CHRYSOVERGIS,  
Of the Faculty of Medicine of Beyrouth.

WE are indebted to Professor Dieulafoy for having grouped under the common head of "the minor complications of Bright's disease" a series of manifestations not in themselves of any great importance and variously distributed which, he says, are frequently observed at the onset and in the course of Bright's disease; so much so indeed that from his point of view their recognition should place the practitioner on his guard and lead him to suspect the existence of chronic nephritis.

Speaking generally, these symptoms are attributed to the accumulation in the blood of toxic substances as the result of inadequate renal elimination. "Almost all the minor complications of Bright's disease," says Dieulafoy—"the cryæsthesia, the electric shocks, the cramp of the calf-muscles, and the itching—appear to me to be the consequence of a slight degree of uræmia. Graver complications, such as headache, attacks of oppression, gastric disturbances, and fugitive prostration, are due to a more marked degree of uræmic intoxication." This opinion, first brought forward by Professor Dieulafoy upwards of ten years since, does not seem to have attracted much adverse criticism. Moreover, it is indisputable that these minor symptoms of Bright's disease are, as a matter of fact, observed at the onset and in the course of chronic nephritis, and I agree with Lancereaux and Germain Sée that they are by no means solely the attributes of this affection. They are met with in subjects whose kidneys were, and have remained, intact, that is to say, although we are agreed in attributing them to a state of intoxication, I decline to attribute the origin of this intoxication to renal inadequacy. The title "minor dyspeptic complications" seems to describe them more accurately, indeed their pathogenesis is essentially due to excessive production of

toxins in the digestive tract and to the superabundance of gaseous formation in the gastro-intestinal canal.

In support of this hypothesis it must be premised that the symptoms in question are met with in dyspeptic subjects just as frequently, if not more so, as in the subjects of nephritis. The best plan will, no doubt, be to scrutinise them *seriatim*, at any rate the more important among them.

We will start with headache, vertigo, visual troubles, noises in the ears and lumbar pain. But does not every dyspeptic complain of these symptoms, not now and then, at distant intervals, but daily, in fact, almost constantly? These various malaises may be present in various affections of the digestive tract, either singly or variously associated, without it being open to us to elicit any sign that would justify our suspecting the existence of a renal affection. Even more significant is the fact that these symptoms get worse or improve coincidentally with modifications of the digestive troubles. Lastly, with regard to their duration, it is true that in most instances they are ephemeral, the generally-received view, but they may, under certain circumstances, last for several hours at a time, even for days, and recur every day for weeks together, so long as the digestive disturbances continue sufficiently pronounced.

Melancholia and prostration, which are also grouped among the minor symptoms of Bright's disease, are also very frequent in dyspeptics, in whom—a matter of daily experience—the temper is usually changed and depression is the rule.

With regard to the itching, it is far from uncommon in these subjects and it is often easy to demonstrate its non-dependence on renal insufficiency by putting the patient on a milk diet, that almost specific treatment of renal manifestations. Not only is the itching not relieved thereby, but in some cases the very treatment causes it to supervene. It has fallen to my lot to meet with a certain number of cases of this kind in persons suffering from gastro-intestinal atony, an affection which has the disastrous effect of depressing the motor activity of the digestive tract, thus promoting stasis, itself the proximal cause of auto-intoxication. I remember one case in particular; that of a man, *æt.* 45, dyspeptic and neurasthenic, who complained of general pruritus. His medical man, having erroneously diagnosed diabetes, he had been put on strict milk diet for ten days, and under its influence the dyspeptic troubles and itching had got worse. The urine, examined on two different occasions, was normal save for an excess of uric acid. I put this patient on a tonic and eupeptic regimen and in five days the itching had quite subsided.

With regard to the "electric shocks" which are assumed to be the initial signs of an attack of uræmia, it is well to note that the victims of this symptom have been so from their youth upwards. They are for the most part congenital neurasthenics, and, as we know, dyspepsia and neurasthenia are intimately associated. The symptom in question is due to spinal hyperæsthesia, a common symptom in neurasthenics. The slightest contact, even certain positions of the body, suffices to determine a reflex contraction of the dorso-lumbar muscles; moreover, one can determine these electric shocks in all neurasthenics simply by rubbing the spine.

Epistaxis, again, is a symptom not infrequently met with in dyspeptics, especially in elderly individuals in whom sclerosis has reduced the resistance of the walls of the blood-vessels, this moreover, being associated with heightened intra-vascular tension, due to the unsatisfactory state of the digestive tract. I remember in particular three dyspeptics (two of whom were also emphysematous) who suffered from frequent epistaxis, and I found myself unable to explain this circumstance on any other ground than a change for the worse in the gastro-intestinal troubles.

These remarks in respect of the minor troubles apply equally to those of a graver kind, and the latter are vastly more significant—*viz.*, symptoms involving the respiratory and circulatory functions—dyspnœa,

palpitations, œdema, polyuria, and pollakiuria, merely to mention the principal ones.

Whenever in a patient whose heart and lungs are sound we witness the supervention of repeated attacks of dyspnœa, we naturally think first of all of renal inadequacy (pre-nephritic dyspnœa), especially if these respiratory disturbances are associated with other minor symptoms of Bright's disease. Now, in my opinion, this dyspnœa is attributable to two different factors, both, however, arising from a common cause—*viz.*, the existence of digestive disturbances. We have, in the first place, the mechanical disturbance caused by gaseous distension of the stomach and intestines, in the second place there is the reflex contraction of the capillaries to which Potain called attention upwards of twenty-five years since, in connection with acute affections of the biliary canals and especially in gall-stone jaundice. To these two principal factors must occasionally be added spasm of the bronchioles and asthenia of the inspiratory muscles, which may play an adjuvant rôle.

I need not insist upon the various forms of this so-called pre-nephritic dyspnœa, for that would take me far from my subject. Suffice it to say that it may affect the form of Cheyne Stokes respiration or occur in a paroxysmal form suggestive of an attack of asthma, the form called by Max Einhorn "dyspeptic asthma." I have seen the latter form in two dyspeptics whose urine showed nothing abnormal.

The dyspeptic troubles do not fail to make themselves felt in respect of the cardiac function. Its influence is seen clinically by cardiac erethism, characterised by frequency of beat and increased force of the systolic contraction, in such wise that the first sound often acquires a vibratory quality. This cardiac erethism is complained of by the patients, who state that they can feel the beating of their heart and even suffer from time to time from attacks of palpitation with præcordial distress. The accentuation of the closure sound of the sigmoid valves is also almost constantly present in dyspeptics, especially when they are passing through one of the acute crises which are, after all, only an intensification of the habitual condition. It indicates an exaggeration of arterial tension caused by spasm of the peripheral arterioles or the vaso-constriction of the vascular system of one or several viscera which may, in the long run, determine cardiac hypertrophy. Auscultation also often reveals in these subjects the *bruit de galop*, a sign formerly regarded as pathognomonic of the prodromal period of chronic nephritis. Is not this exactly what have been described as the cardiac phenomena of the pre-nephritic period?

This cardiac erethism is usually associated with a similar erethism of the vascular system which is productive of certain phenomena of less significance, such as deadness of the fingers, pallor of the face, &c.

If now we pass on to the consideration of a symptom which is generally regarded as a sign of urinary inadequacy, *viz.*, the so-called pre-nephritic œdema, it is impossible not to be struck by the absolute similarity of this œdema and that seen in persons suffering from nervous exhaustion, who also suffer from dyspepsia; in both cases the œdema is usually insignificant in degree and fugitive in duration, limited to the eyelids, the face, to the malleoli, occasionally involving an entire limb, or it may be symmetrical. Even so, the cause is some vaso-motor disturbance, caused, no doubt, by toxic phenomena, but quite independently of the kidneys. These œdemata are characterised by vaso-dilatation of the affected region, following more or less marked and durable paralysis of the local vaso-motor apparatus consequent upon asthenia or inadequacy of motor innervation of the vessel walls. The slowing down of the circulation thus caused promotes serous exudation and constitutes the principal cause of this pre-nephritic œdema, which may be aggravated by the retention of chlorides when this takes place.

During the last few months I have collected notes of three cases of slight œdema, two of them in young females, *æt.* 36 and 26 respectively, and one in an old man, *æt.* 70. In all three cases the analysis of the urine

demonstrated the absolute integrity of the renal functions, and in one the excretion of chlorides was not in excess of the average. On the other hand, it was easy to satisfy oneself in all three cases as to the existence of dyspepsia and neurasthenia, and, as a matter of fact, the œdema disappeared under the influence of a merely antidyseptic and reconstituent treatment.

When circulatory troubles, with a tendency to congestion of the kidneys, predominate in certain dyspeptic subjects, as the result of fatigue or other excess, they are manifested by more or less copious polyuria, which lasts just as long as the acute dyspeptic crisis that started it. This view is confirmed by the fact that all the patients who are able to take careful note of themselves declare that the urinary secretion, independently of any other cause, is never as copious as on days when the dyspeptic condition is worse or when gaseous distension attains an excessive degree.

As to the pollakiuria, according to Dieulafoy it is due to exaggerated excitability of the mucous or muscular walls of the bladder. When, he says, the muscles of the body of the bladder alone are concerned the pollakiuria, early or late, is manifested by more or less pressing and frequent desire to micturate; whereas when the vesical sphincter is affected micturition is often followed by painful spasm. My own view also is that the pollakiuria is due to hyperæsthesia of the vesical mucous membrane, this, however, being caused by active congestion thereof. This state is strictly comparable with the condition of the gastric mucosa met with in the same group of affections which is manifested by vomiting occurring after the ingestion of a certain quantity of food or liquid. In the same way the bladder, of which the congested and consequently hyperæsthetic mucosa cannot tolerate any accumulation of urine, whence frequent and urgent calls to micturition.

To conclude this review of the principal so-called "minor signs" of Bright's disease, we need only refer to the cræsthesia. The excessive sensitiveness of neurasthenics to slight variations of temperature is well known, indeed, even the contraction of the flexor muscles of the fingers and the epileptiform attacks—these major accidents of Bright's disease—may take origin in the self-same order of things. Bouchard has witnessed their occurrence in the subjects of gastro-ectasis and he does not hesitate to attribute them to the absorption of toxic substances resulting from irregular fermentations in the dilated organ.

It is evident, therefore, that all the so-called minor accidents of Bright's disease may be, and often are, met with in dyspeptics. And let us not jump to the conclusion that we are dealing with an association of nephritis and gastro-intestinal trouble. We have often—and I wish to insist on this point—witnessed these accidents in persons who not only never afford any indication of renal disease but who never did so throughout their life's history and whose antecedents, moreover, failed to suggest any plausible cause of nephritis.

I will go even farther, for I do not hesitate to assert my belief that if a patient who has previously suffered from these accidents ultimately becomes the subject of genuine Bright's disease it would be rash to assume that the symptoms in question pointed to the existence of actual renal disease and to refer the onset of the latter to the date of these symptoms. On the contrary, I feel convinced that the etiological factors of these "minor signs" may, in the long run, act on the kidneys, so that these accidents prove not the existence of nephritis, but of a general auto-intoxication, which, later, gave rise to nephritis as an epiphenomenon, so to speak. What remains for me to say with respect to the "minor accidents of Bright's disease" will, I think, justify the views I have expressed.

I have pointed out that two principal factors give rise to these symptoms, one toxic (due to excessive production of toxins within the organism, and especially in the digestive tract), the other mechanical (excessive production of intestinal gases). These we will discuss separately.

It is more particularly in the digestive tract of dys-

peptics that the toxic substances are elaborated, consequent upon irregular fermentations. But to this source of auto-intoxication we must add another, which reinforces the action of the former—*viz.*, the disorganisation of metabolism. This has for result the production of numerous incompletely oxidised and therefore toxic principles; among them we may mention particularly the urinary pigments, regarded by Thudichum as extremely poisonous.

We must bear in mind, too, that this excessive production of toxic elements is further aggravated by the functional shortcomings of the antitoxic organs (liver, thyroid gland, suprarenal capsules, &c.), whence incomplete destruction of these very elements already in excess. The kidney, moreover, is to some extent an antitoxic organ, so that from this point of view it may be conceded to be occasionally in a state of meioptasia without on that account becoming impermeable. Far from being the cause of the auto-intoxication, the renal disturbance, under these conditions, is purely and simply the consequence. But if this double-barrelled toxæmia—excessive production and inadequate destruction of the toxic principles—is allowed to persist, structural changes will often result, either in the kidney or in some other organ which happens to be a *locus minoris resistentiæ*. In this way the patient may ultimately develop genuine renal disease, but it would none the less be an error to regard these minor symptoms as initial manifestations of nephritis, since they only supervene later. Consequently, if in a patient suffering from chronic renal disease we elicit the history, ten, fifteen or twenty years previously, of some of these signs, we shall be justified in referring them to a previously existing dyspeptic state and not to renal inadequacy, since the dyspeptic factor, by the gases and toxins to which it gives rise in excess, has, in the long run, exerted a powerful prejudicial action more powerful even than partial urinary insufficiency, the outcome of hypothetical renal lesions, in the production of the morbid phenomena.

Another argument which militates in favour of the dyspeptic origin of these troubles is the early period at which they make their appearance—*i.e.*, in young persons free from any history of infective influences capable of impairing the integrity of the renal apparatus as may, indeed, be demonstrated by the repeated analysis of the urine, which is shown to be free from any abnormal constituent.

Lastly, it seems to me that the statements of the patients themselves are worthy of attention when they affirm that these disturbances are more marked and severe when their chronic dyspepsia is from any cause intensified, becoming less aggressive, and even disappearing for a time, when the digestive function is discharged more satisfactorily. How often have I not been told that the passage of considerable quantities of flatus, freeing the digestive canal, has been immediately followed by relief of the headache, vertigo, visual troubles and the indescribable *malaise*, from which they had been suffering for several hours?

The action of intestinal flatus is double: first of all it is toxic when absorbed by the intestinal mucosa, and from this point of view the effects are common with those of the other toxic substances of digestive origin. Then, too, they exert a disastrous mechanical action, the distension of the gastro-intestinal canal inducing, through the reflexes, a series of disturbances which react on the circulation.

In view of these two factors—toxæmia and distension of the gastro-intestinal tract—we need only assume a more or less selective action on the vaso-motor centres (an action which may be promoted by a "vaso-motor diathesis") to explain readily enough the pathogenesis of these so-called minor troubles of Bright's disease, since they are attributable *en dernier ressort* to circulatory disturbances. In this respect we are in agreement with the classic writers, the point which I have undertaken to discuss being, not the pathological mechanism of these accidents, but the primary source of the intoxication which gives rise to them.

It is unnecessary to insist at length on the practical importance of the facts which we have brought forward. It cannot but possess an important practical bearing on the prognosis and treatment for us to know whether a patient who, for instance, presents crvæsthesia, pollakiuria or fugitive œdema is really a nephritic subject or is merely suffering from chronic dyspepsia. From this standpoint my opinion is clear enough: the symptoms in question do not justify the assumption of nephritis so long as the methodical examination of the renal functions fails to reveal any evidence of actual disease, such, for instance, as persistent albuminuria, oliguria, the presence of casts or other manifestation of the kind.

### Clinical Records.

#### THE DAVID LEWIS NORTHERN HOSPITAL, LIVERPOOL.

##### *Double Empyæma with Pulmonary Abscess.*

By K. W. MONSARRAT, C.M., F.R.C.S.E.,  
Surgeon, the David Lewis Northern Hospital, Liverpool.

THE patient whose case I wish to shortly relate was a dock labourer, æt. 26. He was admitted to the Northern Hospital on April 2nd, 1902, under the care of my colleague, Dr. Bushby, to whom I am indebted for the notes which were taken before he was transferred to the surgical side.

His illness commenced with headache, malaise, shivering, and pain in the left side of the chest, and on admission he had the usual signs of left basal pneumonia. This subsequently affected the whole of the left lung. For the first fortnight after admission he had irregular pyrexia, varying between 103.8° and 99°; albumin and blood were present in the urine. On April 16th the physical signs in his chest were, dullness over the left back, with diminished breath sounds and impaired vocal resonance; percussion dullness also at the left apex, with a few soft medium râles; the left pleural cavity was explored with a needle, with negative result.

At the end of this fortnight the temperature became regular, in that it rose constantly in the evening to about 102°, and fell in the morning to approximately normal.

On April 20th, he was transferred to my ward, as a second exploration at the left base had revealed pus. On the same day I removed 2 in. of the 8th rib behind, and evacuated about 20 oz. of inodorous pus, inserting a drainage-tube of large calibre.

In spite of this, his general condition did not improve; two days later the temperature reached 104° in the afternoon and continued to rise at night. The local condition at the left base improved, however; the lung advanced and the discharge decreased.

On May 20th the region of the left upper lobe was investigated with an exploring needle; the physical signs here had remained much the same—impaired resonance, diminished vocal fremitus, and indistinct breath sounds. Pus was withdrawn at the depth of an inch, and 1½ in. from the sternal margin.

The next day I removed a portion of the second rib; on palpation the underlying pleura and lung felt hard, dense, and indurated, and the exploring needle again withdrew pus. On incising this area an abscess cavity was opened, lined by broken-down lung tissue, and containing about 2 oz. of pus.

As I was not satisfied that this accounted for the dullness of the whole of the upper part of this side of the thorax, I passed the exploring needle in a direction upwards towards the apex and at once came upon a second collection of pus. On exploration this proved to be an apical empyæma, containing about 15 oz. The abscess cavity in the lung was packed with sterile gauze and a large drainage-tube was passed into the empyæma cavity from the front wound.

For the first week after this operation he still had a considerable rise of temperature at night, attributable to the fact that the upper empyæma cavity did not drain satisfactorily. The man was kept as far as possible on the left side, almost on his face, but he was

stupid or refractory, and turned on his back whenever he thought he was unnoticed. After the ninth day, however, his chart became satisfactory. The abscess cavity in the lung rapidly contracted. On June 7th the tube at the base was discarded, and a week later that in the anterior wound also. When discharged on July 12th his general condition was excellent and the wounds satisfactorily healed.

The interest of the case lies in the combination of conditions present. When, after the first operation, his condition showed no considerable improvement, Dr. Bushby formed the opinion that this was to be ascribed to an inflammatory process in the lung, and before the second operation foretold the probable presence of the abscess which was found.

With regard to the treatment, I followed my usual practice in removing about two inches of rib, in retaining a drainage-tube of large calibre from beginning to end, with no particular device for aspirating the cavity, in refraining from irrigation except under exceptional circumstances, and in getting the patient out of bed at the earliest possible moment, which in the average case is about a week after operation, but which was here delayed by the complexity of the conditions present.

### British Health Resorts.

#### IX.—NEWQUAY (CORNWALL).

[BY OUR SPECIAL MEDICAL COMMISSIONER.]

THE much indented coastline of the Cornish peninsula furnishes numerous natural features desirable for a health station and a holiday resort. Within a comparatively small area great variety exists, but much discretion is needed in selecting suitable places for given cases. The south coast provides many sheltered and picturesque hamlets, admirably fitted for the requirements of the chronic invalid, which are deservedly growing in popularity as winter havens for the aged, delicate children and the subjects of respiratory affections. But of recent years the bold and rugged scenery of the northern portion of the peninsula with its rolling seas, rock-lined coast, and bracing climatic conditions, has become well known to the discerning few as an almost ideal resort, during summer days at least, for the convalescent, and particularly for the overworked in body and overwrought in mind.

Newquay is the best known of the North Cornwall health resorts. It is delightfully situated, and while open to invigorating sea-breezes nevertheless along the banks of the river Gannel admirable shelter may be obtained. Already the place is rapidly assuming the proportions of a small town, and several large, modern, palatial hotels are available for the luxury-loving visitor, while apartments of every description abound.

The immediate neighbourhood is rich in attractions and provides endless opportunities for the artist and naturalist. (a)

Dr. Arthur Hardwick, the Medical Officer of Health, has kindly furnished us with copies of his recent reports, from which we gather the following data:—The population is estimated at 3,300. The true death-rate is returned at 6.06 per 1,000. The birth-rate for 1903 was 13.6 per 1,000.

The mean temperature for last year was 51.3, the mean daily range being only 7.7. The number of days of bright sunshine is given as 286, the sunless days 79.

During the last eleven years, the mean humidity has been 84, the mean maximum temperature 55.9, the mean minimum temperature 47.2, the mean range 8.7, and the mean temperature 51.4. The daily average of bright sunshine is recorded as 4.8 hours. The mean barometric pressure was 29.94 inches.

We have carefully studied during a recent visit the right of Newquay to claim distinction as a desirable

(a) Consult the excellent manual, "Newquay: the Vale of Lanherne and Perranzabuloe," by Fannie Goddard, published by "The Homeland Association"; also Messrs. Ward, Lock and Co.'s convenient guide.

health resort. Nature has well fitted it for such a purpose and although art has done much to secure amusements and interests for the vigorous, pleasure-loving visitor we are of opinion that local enterprise might do much more to preserve and provide those characteristics and requirements peculiarly desirable for many lacking in robust health and absolutely essential for the ailing.

In the immediate neighbourhood of Newquay there are places which might well be made veritable sanatoria for those with phthisical proclivities or actually the subjects of tuberculosis.

We are strongly of opinion that Newquay would prove very serviceable for those conditions so commonly met with in children which a passing pathology termed strumous.

Newquay can be reached by the L.S.W. Railway or by means of the G.W. Railway. It is 266 miles from Waterloo and 297 from Paddington. By the former route Newquay can be reached in about 8½ hours, the latter portion of the journey being by coach from Wadebridge, a distance of 16 miles. Through carriages to Newquay are run by the G.W.R. on their excellent "Cornishman" corridor express trains.

## France.

[FROM OUR OWN CORRESPONDENT.]

PARIS, September 4th, 1904.

### CRYOGENINE AND PYRAMIDON.

In typhoid fever, cold baths constitute the best treatment, and each time the temperature reaches 102°, and every three hours night and day, the patient is placed in a bath of from 82° to 71°.

Nevertheless, an antithermic agent is sometimes useful. Sulphate of quinine is a very familiar remedy, more as a general tonic, however, than an antipyretic.

Two drugs are recommended to take the place of quinine—cryogenine and pyramidon; the former has been put on the therapeutic market by Lumière of Lyons, and has been favourably received by the profession. In a recent pamphlet, Dr. Boutheville indicated the advantages of the drug: complete innocuity, producing no congestion of the kidneys, nor diminishing the quantity of the urine.

On the other hand, its antithermic action is remarkable attaining a fall of nearly two degrees, but its action lasts only a few hours. The first day he gives 15 grs., the second 12, and the third 8, after which daily doses of 8 or 4 grs. according to the effect produced.

In Germany, pyramidon is preferred. Professor Valentin prefers to substitute the treatment by pyramidon for the cold baths.

In twenty-four hours he obtains almost complete suppression of the fever and delirium, while the frequency of the pulse diminishes. The dose he gives is very small, almost homœopathic—half a grain every two hours night and day; in severe cases he gives one grain, while in children he does not exceed one-fifth of a grain. The remedy is administered during the whole course of the malady. These fractional doses are also recommended by Dr. Byk, who has treated in this manner several cases, with invariable success.

### PAIN IN THE EAR.

Hydrochlorate of morphia, grs. vj; sulphate of atropine, grs. ij; water, ℥ss. Six drops in the ear at night.

## Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, September 4th, 1904.

### PSEUDO-HALLUCINATION.

PSYCHOLOGISTS are ready to tell us that all mankind

are living in a state of deception without knowing it. Heveroeh recently brought a boy, æt. 14, before the Bohemian meeting in Prague who knows this, and is quite conscious of the deceit. If he concentrates his mind on some object not immediately before him or connected with the outer world, he can see swarms of fairies with whom he can converse and indulge with them in their pleasures and pastimes. Pain is not mentioned. He is perfectly aware of the duplicity and sometimes has difficulty to shake it off. In straining or making an effort to grasp the meaning of any mundane truth he becomes imperceptibly transformed to a new state, or what psychologists call his "real state." Is this an instaromnium for the deluded? Heveroeh further informs us that this is the son of an alcoholic parent, and fears that this boy is not free from the vice, even at this tender age, which entirely destroys the charm of our philosophy.

### CORRECTING POSITION.

Ostrcil at the same meeting gave a description of a method which he has adopted in converting a face presentation into an occipital presentation. Schatz and Thorn have both promulgated a method of their own which is fundamentally to press the shoulders of the foetus backwards and upwards, inducing the head to rotate forwards and upwards. Ostrcil has modified this, and contends that his methods are better than those of his predecessors, for his can be performed by himself, while the others require an assistant. The whole can be done without any untoward circumstances in the parturition.

### PECULIAR TYPE OF DEGENERATION.

Heveroeh exhibited a girl, æt. 11, with a hereditary form of mental degeneration. The girl often left home and wandered about distant neighbourhoods telling falsehoods of the terror she had of returning to her parents. Her peregrinations were always extended, and her deceit proportionately increased. She always locked herself in her own room, refused to go to school, and at the beginning of her aberrations she was attacked with cramp, becoming pale, with the head turned round and jerking of the foot. She continued sullen and never spoke, but gave signs of great hunger and thirst. These symptoms are uncommon in epileptics, who seldom consciously cover their morbid misfortunes by falsehood. Since the meeting, it is reported that the girl has been found murdered.

### SUBCUTANEOUS INJECTIONS OF GELATINE.

Moll related his experiments on guinea-pigs and dogs with intravenous injections of gelatine. He found that the fibrin of the blood was greatly increased, while the agglutinating power of the red blood corpuscles prevented extravasation. Other albuminoid substances injected, or applied subcutaneously, increased the fibrin, which also favoured coagulation. The action of gelatine declared itself within twelve hours and not beyond twenty-four hours after injection. It is calculated that the blood contains three to four times as much fibrin after this period for three days as is found in the normal condition. Taken by the mouth gelatine has no such effect. It may be mentioned also that sterilisation does not destroy the powers of hæmostasis, thus pointing to the practical application of gelatine as a valuable method of treating obstinate hæmorrhage, although the effects cannot be expected immediately. In practice it may be valued more as a prophylactic than an immediate hæmostatic. It may be noted that the subcutaneous injections and increase of fibrin in the blood do not disturb the digestive organs. He exhibited coagula to the members, which substantiated

his description of agglutination and thickening of the blood. As a general rule, when any albuminous body is injected subcutaneously, leucocytosis is produced along with the increase of fibrin.

In the discussion Imhofer said that he had employed gelatine subcutaneously with the best results for local hæmorrhage, such as in epistaxis. He found it excellent when applied locally with pledgets of carbolised lint to a bleeding surface. Munzer thought that the danger of injecting gelatine should not be under-rated. Besides the weakening effects that usually followed, literature was not without its example in post-mortems, where the *exitus letalis* followed suddenly after the injection of gelatine for aneurysm. Nonne, of Hamburg, has put on record a good example as a warning, where a young man, full-blooded, exhibited a slight pulmonary hæmorrhage which induced the attendant to inject gelatine. The man died suddenly, and in the lung were found a few emboli which had been the cause of death. If every drug and method of treatment has failed, gelatine may be resorted to as a last resource.

### The Operating Theatres.

#### GREAT NORTHERN HOSPITAL.

OPERATION FOR DISTENDED GALL-BLADDER.—Mr. PEYTON BEALE operated on a woman, æt. about 50, whose history was as follows: About five weeks before admission she observed her abdomen becoming larger with a sense of fulness and increased weight. As far as could be ascertained she had had no other symptoms except a slight malaise till a few days before admission, when she was seized with violent pain in the right iliac region, in the epigastrium and in the back; this was accompanied by a rise of temperature to 103°. On admission there was felt in the abdomen a movable tumour, occupying the right iliac region in the position of the cæcum; the tumour was about the size of a foetal head, apparently globular in shape and very hard; it was fairly freely movable and its manipulation gave rise to considerable pain, referred chiefly to the epigastrium and the dorsal spine; the temperature was now normal, but the patient looked and seemed ill. The medical man who sent the case considered it to be a suppurative appendicitis. This, however, was negated by the mobility of the tumour and its globular shape. As it was impossible to make any definite diagnosis, and as the woman's general condition was becoming worse, the following operation was performed: An incision of about three inches was made about two inches anterior and parallel to that usually employed in performing lumbar colotomy. On opening the peritoneum a large globular tumour, very hard to the touch, was felt and it was obviously a very much enlarged gall-bladder. After separating a few adhesions it was without difficulty brought out through the wound, and it was then seen to be a sausage-shaped swelling containing fluid at very great tension. It was then punctured and thick treacly-looking bile escaped. The gall-bladder was next opened freely and four large gall-stones were evacuated, together with about a pint of the inspissated bile. The gall-bladder was washed out with hot, sterilised water, the interior being carefully examined to make sure that there was no stone in the duct. The lumbar incision was then closed with the exception of one inch, to the edges of which the open gall-bladder were stitched. Mr. Beale said that the history of the case was so misleading

that any diagnosis before operation was impossible: the tumour seemed to be globular when felt through the abdominal wall because there were adhesions between it and the liver, stomach, &c., around its upper part; it had dragged the liver down to such an extent that the tumour was lying on the cæcum; as it turned out the incision was in the most favourable position that could have been chosen, though, of course, it was much too far back and too low down to be of use in any ordinary case of enlarged gall-bladder. As it was it allowed the gall-bladder to drain thoroughly well, and Mr. Beale proposed in about a week's time to sew up the opening in the gall-bladder and drop the viscus back into the abdominal cavity. He had come across a good many enlarged gall-bladders which had been mistaken for enlargement of the kidney, but had not before seen one which was resting on the cæcum. He said that he had made the incision so far back because he was in the habit of using this incision for reaching appendix abscesses, and at the time of operation and from the previous history this case was thought not unlikely to be of such a nature.

#### MIDDLESEX HOSPITAL.

OPERATION FOR THYROID CYST.—Mr. KELLOCK operated on a man, æt. 24, who had been admitted for a tumour situated in the right lobe of the thyroid gland, which had been present for some years, and which latterly had somewhat rapidly increased in size, but had given rise to comparatively few symptoms. The patient was a thin, anæmic man. Situated low down in the right lobe of his thyroid gland was a tumour rather larger than a pigeon's egg, which was little noticeable when the patient was at rest, but when he performed the movements of deglutition, it became very evident, rising up, as it were, from the deep parts of the neck behind the clavicle. The growth felt firm and circumscribed, but its situation rendered it difficult to say whether fluctuation could be obtained in it. The rest of the gland appeared unaffected. Except that he was somewhat anæmic the patient's general condition was good. The man having been anæsthetised, a vertical incision, about three inches in length, was made slightly to the right of the middle line, reaching downwards almost to the upper angle of the sternum. A few bleeding vessels in the soft parts having been secured, the right sterno-hyoid and sterno-thyroid muscles were separated and held aside by retractors, and the lobe of the thyroid containing the tumour exposed. A slight incision having been made in this, the tumour itself came into view. It proved to be a somewhat thin-walled cyst, and on an attempt being made to shell it out from the substance of the gland, the wall ruptured, and the contents, which consisted of about two or three drachms of fluid glistening with cholesterin crystals, escaped. The edges of the opening in the cyst were then taken hold of, and the entire cyst wall easily detached and removed. The hæmorrhage from the cavity was slight, and easily controlled by plugging for a few minutes with gauze. A small drainage-tube was then inserted into the cavity in the thyroid gland, and the superficial structures and skin closed round this, with fine silk for the superficial structures, and horsehair for the skin. A dressing of cyanide gauze was then lightly applied by means of a bandage passed round the neck and under the arms. Mr.

Kellock said that unilocular cysts of the thyroid were comparatively rare in men. Before the operation it had been difficult to say whether the tumour was a single cyst or a multilocular cystic adenoma. It was possible that it was of the nature of an adenoma with one large cyst, but the thinness of the wall and the character of the contents, the latter being quite fluid and containing many cholesterin crystals, would suggest that it had some other origin. He further pointed out that formerly the treatment of these cysts consisted in either simple tapping with or without the injection of some slightly irritant fluid, or by incision and drainage, but the operation he had just performed showed how comparatively easy a matter it was to deal with such things in a more radical manner. The drainage-tube which had been left leading down to the cavity in the thyroid was for the purpose of preventing any accumulation of blood, which might be injurious from its pressure, and this tube would be removed, he hoped, in the course of thirty-six or forty-eight hours. It was important, too, in these cases, he thought, to apply a very light dressing for the same reason, and to keep the patient's head and neck quite still, lest any movement might set up fresh bleeding from the damaged surfaces of the gland.

WEDNESDAY, SEPTEMBER 7, 1904.

#### HOSPITAL ISOLATION AND SCARLET FEVER.

THE articles on scarlet fever and its treatment by hospital isolation, contributed to our columns by Dr. Killick Millard and Dr. Hubert Biss, deserve careful study. It would not be wide of the mark to say that until three or four years ago, when Dr. Dean Marriott, of Nottingham, and Dr. Killick Millard raised the question of the utility of fever hospitals as controlling factors in the spread of infectious diseases, no serious doubt on the subject was entertained by sanitarians. Indeed, it was a prime article of the hygienic creed that isolation hospitals, as they are generally called, formed the chief bulwark

of defence against infection. The opinions of those who at that time courageously attacked this belief were scouted as ridiculous, and with feathers much ruffled at the audacity of their critics medical officers of health endeavoured to treat the onslaughts as frivolous and beneath contempt. But the spirit of the reformer is stimulated by rebuffs, and by dint of in-season and out-of-season efforts to win adherents to their views, Drs. Marriott and Millard gradually gained the ear of an increasing number of medical men. The general attitude of the profession towards the question was reflected in the medical journals, and, one by one, these organs, from showing a front of uncompromising hostility, have come to lend their voice, feebly and hesitatingly it is true, in aid of the demand formulated by Dr. Millard for an intra-professional inquiry into the subject. The question at the moment stands in this position. The critics of the isolation hospital system, or, as they more correctly describe it, the aggregation hospital system, have brought forward good evidence to show, first, that the hospitals have not been a striking success as preventives of scarlet fever incidence, and, secondly, that the hospitals have many grave drawbacks. Does the good of the system outweigh the evil, and, if so, is the amount of good effected commensurate with the enormous sums expended? Since a widespread feeling of dissatisfaction exists, we think that such an inquiry as that suggested ought not to be postponed. For it must be remembered that this agitation is not a hole-and-corner affair. Many medical officers of health have individually and collectively expressed their approval of the proposition; the leading journals of the profession have now given it their support; and lastly, at the Congress of the Royal Institute of Public Health at Folkestone this summer a motion in favour of inquiry was passed by a large majority. The question, then, may be described as a burning one. It will be noticed that Drs. Millard and Biss, and, indeed, most of those who have taken a prominent part in the matter, have confined their attention to the isolation of scarlet fever. In this they are wise, for whatever may be the case with the other infectious diseases, it is in the instance of scarlet fever that the anomalies are most striking. As Dr. Biss showed in the first part of his paper, the prevalent type of scarlet fever to-day is an exceedingly mild one, and it may well be questioned whether so benign a disease deserves the lavish expenditure of money now bestowed upon it. Dr. Biss' present contribution is a particularly valuable one, not only for its erudition and insight, but for the temperate and scientific manner in which he handles a question which, as he justly says, should not be regarded as polemical. The considerations he adduces from the past history and present condition of scarlet fever in this country are exactly those which should possess the mind of anyone who wishes to do justice to this important matter. The evils, he maintains, are inseparable from aggregat-

ing such people, especially when the bulk of those people are young children, and deserve serious attention. The records of post-scarlatinal diphtheria, post-diphtheritic scarlatina, measles, whooping-cough, and chicken-pox, which belong to all fever hospitals, however well managed, have to be weighed against the good that patients may derive from their sojourn in these institutions, and one cannot look to any marked diminution under this head till the present ward system is replaced by the much more expensive cubicle arrangement which is found in some of the Continental hospitals. After all, however, the crux of the whole question is whether there is, or has been, as the result of the wide multiplication of fever hospitals, any marked diminution or restriction in the prevalence of scarlet fever. This, as Dr. Millard observes, is a point that must eventually be decided by statistics, and without a combined inquiry it is difficult to see how far-reaching and authoritative figures are to be obtained. The belief that by separating patients suffering from scarlet fever from their healthy fellows a certain number of attacks must be prevented is a natural one. Dr. Boyd gives in the August number of "Public Health" details of a careful investigation he made at South Shields, which tended to show that scarlet fever has of late years prevailed more largely in the better class districts than in the poorer ones—a result he is inclined to attribute to a larger number of cases of the disease being removed to hospital from the less well-to-do parts of the town. But without general inquiry and free comparison of various towns no final or satisfactory solution of the problem can be expected, and we should strongly urge such an inquiry ourselves. Whatever it may bring to light, we think that opponents of the hospital system will prove to be right in saying that the success of that system has been far from commensurate with the predictions of its founders.

#### EPILEPSY OR DRUNKENNESS?

As members of a scientific profession medical men are closely interested in the question of criminal law administration. At any hour of the day or night the general practitioner is apt to be summoned by the police to attend a sick or injured person, a service for which he is paid a miserably inadequate fee, obtainable only through the medium of circuitous official channels. If the General Medical Council were really a body concerned with the interests of the profession, this small but irritating matter of police attendance fees would long ago have been settled on a satisfactory basis. The duties of the medical man thus summoned are often of a most difficult and responsible nature. He has to determine between the various forms of insensibility, and upon his decision may rest the reputation and sometimes the life of a fellow-citizen. As a rule, in the cases where disaster follows the confusion of various other forms of insensibility with that due to alcohol a surgeon has not been called by the

police. On the whole, the official police surgeons are a highly-trained and experienced body, in whose hands the risk of erroneous diagnosis is reduced to a minimum. The chief effect of the present system is that they are not called often enough, because the police trust their own judgment and do not realise that a drunken man is in a position of more or less imminent danger. The majority of the police throughout the United Kingdom are untrained even in the elementary knowledge of ambulance work, whereby they would be able to recognise many of the conditions of sickness that are commonly mistaken for drunkenness. With a little training, for instance, any constable of ordinary intelligence could learn how to distinguish epilepsy from alcoholism. A modicum of such elementary knowledge would have recently saved a London magistrate a good deal of vexation. An unfortunate epileptic, who is said to be a total abstainer and of irreproachable character, was brought up in custody by the police on a charge of drunkenness. The father of the accused states that he was prevented going into court to give evidence as to his son's liability to epileptic seizures. However, other evidence was forthcoming, and the magistrate, Mr. Plowden, discharged the prisoner with the unfortunate remark that he would give him the benefit of the doubt. It is not clear why a man who has been taken into custody on an unfounded charge, and kept for the night in a police cell, should be dismissed with a "whitewashing" of that dubious and grudging kind. The accused was either drunk or not drunk, he was either an epileptic or not an epileptic, he was either innocent or guilty of the charge of drunkenness. It was perfectly open to the police to ascertain the fact as to the epilepsy, which would have afforded immediate confirmation or otherwise of that part of the defence. Instead of so doing, the police, if we are to take the statement of the father, excluded such evidence from court. The fault appears to lie in the police system, which regards it as a stain on its efficiency if a charge be not substantiated at all hazards. A great deal of the possibility of minor police injustice or tyranny would be avoided by having all sick and insensible persons in custody examined by a medical man. Another safeguard would be the possibility of immediate appeal from any criminal judgment, no matter how trivial the case. It is clearly intolerable that a respectable citizen should be shut up in a police cell because the police have had neither the desirable knowledge to recognise the fact of his being in a state of epileptic seizure nor the sagacity to consult a surgeon as to his condition. Still more intolerable is it that he should be dismissed next morning by the magistrate with a curt remark that left the police charge in doubt. The blind acceptance of police testimony without any attempt to bring corroboratory evidence constitutes a radical defect in minor criminal proceedings. The history of epilepsy, to say nothing of the strictly temperate habits of accused, would have been

confirmed in a few minutes by a couple of friends or relatives in the witness-box. The matter is one of universal importance. At any moment any citizen, no matter what his standing or respectability, may be taken ill in the street and carried off to a police cell. In many cases the error has ended in a tragedy. It is time the whole matter were investigated by an authoritative Royal Commission so that the margin of error in the case of persons taken into police custody in a state of unconsciousness may be reduced to a minimum. Meanwhile, the medical profession, which is brought into direct daily contact with the disastrous defects of the present police system, may do much to educate the public and to indicate the way of reforming a force which, in spite of its errors, we could not do without.

### Notes on Current Topics.

#### Typhoid Infection.

We are always inclined to become somewhat stereotyped in our beliefs and practices, and hence it comes that having learned, quite correctly, that faecal contamination of drinking water is the commonest method of spreading typhoid infection, we proceed in the main as if it were the only possible method. Recent experience has proved, however, that various other means of infection have more than a theoretic interest, and that a pure water supply is not the sum-total of safety. India and South Africa have shown that wind-blown dust is under some circumstances of much greater importance than drainage as a factor in the contamination of water, while its influence affects all foods and drinks as well, unless proper precautions are taken. Various observers have shown, too, that flies may, and do, act as carriers of infection. Much more important, however, than either dust or flies are the deductions that follow from the discovery of typhoid bacilli in the urine. It is now known that not only during the height of the disease, but often for weeks after convalescence, the urine of typhoid patients contains large numbers of live bacilli. There can be but little doubt that this constitutes a serious source of infection which, up to the present, has been entirely overlooked. In the treatment of typhoid fever it has long been the custom to destroy or disinfect the stools, while little care has been taken to deal specially with the urine. In reality, it should be handled with the same extreme caution with which a bacteriological worker treats the virulent cultures in his laboratory. It should be remembered, too, that patients having left hospital as cured may still be passing bacteria in their urine, and may thus become a source of danger to others. Consequently, equal care should be taken to be sure that the urine of typhoid patients is free from bacteria before they leave hospital as is at present taken to make sure that diphtheria patients no longer have diphtheria bacilli in their mouths.

#### Sir Thomas Browne.

THE proposed memorial to Sir Thomas Browne, to which members of the medical profession are asked to subscribe, has drawn a strong protest from Dr. Conolly Norman, of Dublin, who in a contemporary appears in the character of *advocatus diaboli*. "Science and humanity," says Dr. Norman, "are the watchwords of our profession. The author of 'Religio Medici' was neither scientific nor human." These charges he proceeds to prove, we think, with considerable success, by reference to Browne's conduct in the trial of two country women at Bury in 1664, on a charge of witchcraft. The principal count against them was that by their machinations certain children had been afflicted with "fits." Browne, being present in court, and asked by the judge for his advice, "declared that he was clearly of opinion that the fits were natural, but heightened by the devil, co-operating with the malice of the witches, at whose instance he did the villainies." Influenced by this expert opinion, the jury convicted, and the women were executed. It may be argued that belief in witchcraft was universal in Browne's time, but this is by no means true, as it should be remembered that he was contemporary with Hobbes, Butler and Locke. And one of the many points on which he prides himself is that he is neither fanatic nor enthusiast. Dr. Norman makes out a good case on the two charges on which he indicts Sir Thomas Browne, and many lovers of literature who demand thought as well as style in a writer will not be sorry to see this depreciation of one whose reputation is greatest among those who have never opened his works.

#### Serum-therapy.

ONE of the most interesting discussions which took place at the meeting of the British Medical Association a few weeks ago was that on the serum treatment of disease. The Executive acted wisely in inducing the medical and pathological sections to combine for the purposes of discussion, since the subject is at present not merely one of primary practical importance, but has also theoretical bearings of the widest. Discussed, as it is bound to be in such a gathering, from the very different standpoints of clinical and laboratory experience one might have expected greater differences of opinion than actually appeared. In fact, such differences as did appear were rather superficial than real, and on the whole some important results stand out. The main point is that the anti-bacterial sera, of which anti-streptococcus serum is the best known, may definitely be regarded as valueless, while there is a possibility of their being actually deleterious. The clinical evidence has never been decisive, while on theoretic grounds the arguments against them are so strong that, as Dr. Bullock put it, "no respectable laboratory thinks of manufacturing them now." As regards the antitoxic sera, on the other hand, such as the anti-diphtheritic and anti-tetanic preparations, they are now outside the region of

controversy as remedies of established worth. In regard to the method of their use, it is well to remember Dr. Martin's advice, based on experimental grounds, that in urgent cases the serum should be administered intravenously rather than subcutaneously, as a speedier result can thus be obtained.

#### Interrupted Circulation in Treatment.

As long ago as the time of Ambroise Paré, damming of the circulation above a fracture in a limb was recommended as conducive to rapid healing. The treatment never seems to have been widely adopted, though many writers at various times mention it as a successful measure in local lesions. To Dr. Ewart, of St. George's, is due the credit of reviving the method, and applying it with success in cases of rheumatoid arthritis. He empties the veins of blood as far as possible by raising the limb he is about to treat, and by firmly stroking it. He then applies a tourniquet tightly above the affected joint for half a minute or longer, and relaxes it. The application of the tourniquet is, of course, accompanied by blanching of the part, while its removal is immediately followed by a sudden hyperæmia. This alternation of anæmia and hyperæmia is repeated rapidly four or five times. The treatment may be given once or twice a day. In the cases treated by Dr. Ewart he has noticed a rapid decrease of swelling and diminution of stiffness, and he thinks the treatment may have a wide applicability.

#### The Fear of Death.

A WELL-KNOWN writer—we think it was Mr. George Meredith—made the remark some time ago that our profession, in common with the clergy, was injuring the English race by increasing their fear of death. We suppose there is a certain truth in the charge that medical science increases the dread of death, since it makes death appear more avoidable than formerly. While "man is mortal" is as universal a law as ever, yet each man's mortality at a particular moment, being known to be governed by the conjunction of certain natural laws, allows a possible chance of escape. We are not as ready to fold our hands and say "kismet" as formerly in the presence of an epidemic; on the contrary, we are inclined to ask who is responsible, for, as someone has said, for every epidemic of typhoid fever someone should be hanged. If death here and now has thus become less a matter of certainty and less a matter of course than formerly, its very unfamiliarity makes it more feared. Life, too, has a sacredness in our civilisation which is comparatively a new thing, and is bound to make the negation of life seem a greater evil than in old times. But, is it true that there is in reality more dread of death than formerly? We think that this fear of death is in truth a very exaggerated thing. In health one naturally and properly wishes to remain alive, but beyond this we think whatever fear may be present is rather of suffering than of death.

Those who have seen many people die of disease are inclined to the view that dread of death is comparatively rare. Death is natural, and the person meets it as naturally and impassively as at the end of a busy day he meets his night's sleep. Where death is dreaded it is rather for the sake of those left and more for sorrow at breaking a happy career than for anything in the essence of death itself.

#### Hungry School Children.

IT is a self-evident fact that food must be furnished before any mental pabulum can be properly assimilated. The revelations of recent evidence before the English Inter-Departmental Committee on Physical Deterioration certainly seem to show that failure to recognise this principle, either from wanton neglect or abject poverty, is only too prevalent among the poor of our crowded cities. According to the headmaster of one of our Board schools, 12 to 15 per cent. of the children are unable to give their minds to their lessons on account of actual hunger, which condition was proved to exist in several cases by the eagerness with which some children devoured stale crusts of bread given to them as a test. During hard winters the proportion of famished scholars in the poorest schools is stated to be even higher. In some instances it is not so much the want of food as its quality and the irregularity in meal-times that chiefly touch the physical welfare of the children. The matter was more than once fully discussed by the late London School Board, who appointed a Special Committee in 1898 to consider the question. It was then resolved that in case of culpable neglect of a parent to provide food for any child the Board should have power to prosecute for cruelty, but this proposal was defeated by a full Board. Private enterprise and philanthropy have done much to ameliorate the impoverished conditions of school children, and on this account educational authorities have been unwilling to urge that the matter should become an item of public expense. Dr. Macnamara, M.P., has recently drawn attention to the whole subject in the daily press, and he is of the opinion that the support of the great urban educational authorities should be secured before pressing the legislature.

#### The Demoralisation of the Consumptive.

THE view that certain temperaments are peculiarly prone to particular forms of disease was firmly held by physicians of the old school. It is now customary to assume the air of the agnostic in regard to much in medicine which cannot be demonstrated by so-called methods of precision. But every thoughtful physician knows that in his own and his patient's physiological upbuilding, and in the initial action and reaction between them, there are elements altogether beyond the ways of the mere laboratory investigator. Some day, perhaps, we may unfold something of the closely draped mystery of the psychology of the pathological. Meanwhile, much that is of

suggestive value has accumulated in regard to the psychology of the phthisical. We do not intend to describe the various traits so frequently conspicuous in the character of the consumptive patient, but are desirous of urging on all who are in any way responsible for the management of these cases the paramount importance of recognising those psychical features which, if rightly controlled, make for mental and moral development, and if neglected lead to as slow but sure deterioration of moral character. We know, as the result of much personal investigation of so-called sanatorium life, that at the present time in connection with what is known as "open-air" or "hygienic" treatment of consumptives there is often a deplorable ignorance of the psychical requirements of the healthy life, and in many institutions the procedure adopted is such as tends to develop selfish, morbid introspection and moral decadence. In short, there is danger in the eagerness to improve physical condition of altogether forgetting the culture of the psychical side of the patient, and so there is in process much that is making for the demoralisation of the consumptive.

#### Five Abdominal Sections in Four Years.

OUR American brethren have never been reproached with want of courage in the pursuit of surgery, and they have certainly educated their patients to look upon "the knife" with much less horror than our own conservative population usually entertain towards it. A certain Mrs. B., a patient of Dr. Howard Crutcher, appears to have become so much inured to abdominal operations that he had finally to dismiss her from his *clinième* as he assured her that it was against his principles to do half a dozen laparotomies on the same patient. In 1894 Mrs. B. was first seen and operated on for rupture of a large pelvic abscess. Everthing went well, in spite of a gloomy prognosis that Dr. Crutcher felt it his duty to give, but some months after convalescence a ventral hernia developed. A second and completely satisfactory operation was performed for its relief. About a year after this, Dr. Crutcher was called to see her for the third time, and found that she had appendicitis. On opening the abdomen he discovered a gangrenous appendix with two perforations; appendicectomy was done, and the patient again recovered. In 1896 Mrs. B. consulted him again, this time for a growing swelling in the pelvis. After a period of observation, Dr. Crutcher decided to operate, and in doing so he came upon an ovarian cyst, which was duly removed. After an uneventful recovery a period of two years' good health followed, but 1898 found her with another growth in the pelvis. Operation was deferred, as Dr. Crutcher was unwilling to interfere if he could avoid doing so, but the growth increased in size, and laparotomy was performed once more. Two large intra-ligamentous cysts filled the pelvis, each containing forty ounces of fluid, the contents of the left cyst being almost black, those of the right clear and limpid. The cyst-walls were stitched to the peritoneum, and

the cavities packed with gauze. They both closed in a short time. Mrs. B.'s final appearance in Dr. Crutcher's consulting-room was occasioned by another ventral hernia, but, as we have already said, he declined to operate again. The last news that came to hand with regard to her was that she was being cured by the faith-healers.

#### The Functions of the Dental Pulp.

A WIDER knowledge of the extreme delicacy of construction of every part of the body subserving a special purpose would undoubtedly tend to prevent its abuse or neglect. The intricacy of the visual mechanism and the consequences of overstrain are quickly appreciated by the public, but when it comes to the teeth they are simply regarded as bits of bone, able to stand an unlimited amount of wear and tear. The dental pulp itself, with its wonderful fibrils, is at least as delicately fashioned as the retina, though it may not be such a highly specialised tissue. The vital action of this vascular and sensitive substance is by no means sufficiently recognised. Dr. R. R. Andrews, in a paper read before the fifty-fifth Annual Session of the American Medical Association, in the Section of Stomatology, laid particular stress upon the truly vital functions of the dental pulp, the chief of which is the protective influence exerted upon the dentine. By virtue of its odontoblasts, the cells nearest the surface, any weak place in the dentine is speedily repaired, and, indeed, attempts at calcification may be seen under the microscope throughout the whole of the superficial layer. Its great vascularity and the thinness of the walls of the blood-vessels suggest that the leucocytes play an important part in the absorption and destruction of deleterious substances. When the tooth is allowed to decay the vital action of its pulp is then overwhelmed, and it is a well-known clinical fact that the tubercle bacillus may find an entrance into the body through the channel of a carious tooth. The restoration of function of the dental pulp, in other words, conservative dentistry in the highest sense, is the whole aim and object of odontological science. *Conserve quam extrahere.*

#### The Fate of Biliary Calculi.

ONE of the most fascinating chapters in medicine is that which deals with the formation and destiny of the various calculi that are met with in the different organs, glands and ducts of the body. Their origin is frequently shrouded in obscurity, and the complications to which they may give rise are both numerous and sometimes puzzling. Thus, no less than twenty-three possible complications of gall-stones have been described, many of which are absolutely fatal unless the condition be promptly recognised and an immediate operation performed. The relative merits of medical and surgical treatment in cases of cholelithiasis has long proved a favourite theme for discussion at the learned societies, and there can be no doubt that the former method is of great value as a prophylactic. If the formation of calculi can be prevented altogether, so much the better, but when once they are present:

the individual is not free from danger until they have either been removed by operation or passed *per vias naturales*. The most common complication of gall-stones is their impaction within the bile or cystic ducts, perforation of which not infrequently occurs. The fate of a moderately large biliary calculus is interesting to trace. Intestinal obstruction, ulceration, or perforation may occur as the result of a fistulous communication between the gall-bladder and bile-duct and the duodenum. The virulence and activity of the bacillus coli is apt to be much increased under such circumstances, so that septic changes involving the mucous membrane of the passages traversed by the stone may arise. One of the most remarkable complications is the elimination of the calculus directly through the skin of the abdomen, which cannot be regarded as a common event. M. Princeteau (a) has recorded the case of a woman, æt. 59, in which a good-sized gall-stone was ejected spontaneously through the right hypochondrium, a minute sinus having previously existed at the spot.

#### Shakespeare's Grave.

It would be difficult to match the so-called Shakespeare-Bacon controversy in any age of which we have record. If ever an example were needed to illustrate the hold that ingenious sophists can obtain over thoughtful, well-educated minds, the wrangle over the personality of the author of Shakespeare's works would surely furnish one of the most remarkable. When people seriously set themselves to work on iconoclasm, and are prepared to admit evidence of any kind, astonishing results can be obtained. A well-known playwright of his day, whose personality and productions were as well known to his contemporaries as those of Mr. Pinero and Mr. H. A. Jones to us to-day, has been conclusively shown by different parties—(a) to have been somebody else; (b) to have been two people; and (c) not to have existed at all (as an author). Those who are old-fashioned enough to enjoy the greatest dramatic masterpieces of any time, and credulous enough to attribute their authorship to the man who wrote them, stand aghast at the latest proposals of the fanatics, for they are little else, who wish to open the poet's tomb in search of confirmation for their fads. What good could possibly result from such a procedure it is impossible to conceive. Knowledge of personal appearance of Shakespeare is derived principally from the famous "Droeshout" paintings and the bust in Stratford church; each is inartistic, and probably fanciful. They differ greatly the one from the other; indeed, their chief points of resemblance are the fulness of the hair over the ears and the baldness of the crown of the head. All the other portraits are of doubtful authenticity, and even more widely divergent. After a lapse of three hundred years one could not hope to discover from a grave seventeen feet deep any remains that could possibly lead to identification. The cause of science or of justice may occasionally de-

mand the exhumation of a body, but it is sheer stupidity to expect than any useful information could be derived from desecrating Shakespeare's grave. We would be inclined to associate ourselves with the primitive curse contained in the doggerel inscription over the dramatist's tomb on those who wish to disturb his bones.

#### The Sense of Smell.

In civilised man the sense of smell is a faculty undoubtedly much less developed than among his primitive ancestors; indeed, there is anatomical evidence that the olfactory lobe is but a remnant of what it has been in lower animal forms. To those addicted to travel on the Continent this state of things may be advantageous, but there is no doubt that in medicine the sense is often one of great value. Typhus has a characteristic odour, which to those accustomed to deal with the disease is of itself sufficient to establish a diagnosis, and to some, indeed, even typhoid is recognisable on like grounds. Persons suffering from tuberculosis of the lungs are perceived by their attendants to have a stale, sour odour about their bodies, probably from decomposition of sweat, and most doctors and nurses are acquainted with the acid smell of patients with acute rheumatism. These are only some diseases among many in which the nose is a useful aid to diagnosis, and in chemical tests and pathological observation the olfactory sense is often of no little help. The sense of smell can be cultivated, and to medical men may be commended the olfactory exercise which serves the Japanese not only with a means of educating a neglected faculty, but with a pleasant pastime. "Incense snuffing," as it is called, is a ceremonial that has been in vogue for four centuries in the land of the chrysanthemum, and the rules of the game have been elaborated in weighty treatises. The principle on which it is founded is that of competition. The host of the *kiki-ko* party brings in a tray covered with different kinds of incense, to each of which names or numbers are given. These varieties of incense are then burned alone and in combination, and the guest who identifies the largest number by their smell is awarded a prize. An interesting point is that between the smells the competitors are provided with vinegar to sniff, in order to bring the Schneiderian membrane into working order again. By such an education the olfactory acuity of the Japanese is said to increase wonderfully. Perhaps the General Medical Council may see its way to add a course of sniffing to the list of obligatory studies in the medical students' curriculum.

#### The Diagnostic Value of the Strawberry Tongue.

THE anxiety with which the tongue is regarded by the physician in a suspected case of scarlet fever is in itself a sufficient indication of its diagnostic importance. As we all know, a thick white fur speedily develops upon the surface of the tongue through which some of the fungiform papillæ may generally be seen protruding. In three or four days

(a) *La Médecine Moderne*, August 10th, 1904.

this coating disappears, leaving a raw surface studded with injected and enlarged papillæ. The appearance of a ripe strawberry is by this time fairly well imitated. Dr. Foord Caiger states that a renewal of the normal epithelium occurs early in the course of the second week of the disease, when the tongue assumes its usual aspect. In common with most physical signs, however, a too absolute reliance cannot be placed upon the "strawberry tongue," for, according to Dr. J. F. Schamberg, (a) this sign is not present in every case of scarlet fever, indeed, in mild cases the tongue may appear quite normal. Redness of the tip and edges, the remainder being coated with fur, is by no means characteristic of scarlatina alone, for a somewhat similar appearance may be observed in typhoid fever. Again, mere enlargement of the papillæ occurs in some varieties of superficial glossitis, in which the resemblance in question is only a distant one. The healthy tongue may also exhibit considerable variation from time to time in the size of its papillæ, according to the degree of congestion and activity of the mucous membrane of this portion of the alimentary canal. In erythema scarlatiniforme, a disease which, perhaps, simulates scarlet fever more closely than anything else, the "strawberry tongue" has been seen in its most typical form. The appearance of the tongue must therefore be taken in conjunction with other physical signs, such as the sore throat, the rash itself, and the constitutional symptoms, as an aid to diagnosis.

#### The Royal Commission on Extra-Asylum Lunacy.

A MUCH-NEEDED Royal Commission has been at length appointed to inquire into the existing methods of dealing with idiots and epileptics, and the imbecile, feeble-minded, or defective persons not certified under the Lunacy Laws, and to report as to the amendments in law or other measures which should be adopted in respect of their care, training, and control. The following have been appointed by His Majesty the King as members of the Commission:—The Marquis of Bath (Chairman), Mr. William Patrick Byrne, C.B., Dr. Frederick Needham, Mr. Henry David Greene, K.C., M.P., Mr. Charles E. H. Chadwyck-Healey, K.C., Rev. Harold Nelson Burden, Mr. Charles Stewart Loch, Mr. Charles Hobhouse, M.P., Mr. Willoughby H. Dickinson, and Mrs. Pinsent. While recognising the difficulties that inevitably surround the selection of suitable members for a Royal Commission of Inquiry, we cannot help regretting that the medical profession is so inadequately represented. Dr. Needham is, of course, a tower of strength in himself, but in a matter of the kind to be investigated he should have been strengthened by two or three of the most experienced asylum authorities obtainable in the United Kingdom. The proportion of lawyers to medical men on this Commission repeats the traditional legislative attitude with regard to mental disease—namely, law first and medical science afterwards—*magno intervallo*.

(a) *Journ. Amer. Med. Assoc.*, August 6th, 1904.

#### Smoking Without Harm.

FROM Germany comes good news—it is possible to smoke without risk, if proper precautions are taken. Bamberger, who writes on the subject, divides consumers of tobacco into two classes—the dry smokers and the wet smokers. The former consist of those who puff their cigars through mouthpieces, and thus keep the ends dry. It includes also those who prefer the domestic pipe to the allurements of more costly methods of destroying tobacco. Wet smokers are those who chew their cigar ends or keep them constantly moist with saliva. These careless individuals have the mouth constantly filled with saliva in which the tobacco extracts are dissolved, and now that the spitting habit is forbidden they are forced to swallow quantities of this noisome juice. Consequently they suffer far more from the evil effects of tobacco than their "dry" brethren, and if in addition the "wet" smoker is addicted to alcohol his condition is a parlous one indeed. Bamberger would have medical men warn their patients to take to dry methods of smoking, and he suggests that in the stem of the cigar-holder a piece of cotton saturated with perchloride of iron should be placed, as thereby many harmful products of tobacco-smoke are rendered innocuous. It is, however, one thing for the physician to advise and another for the patient to follow the advice. To pack one's cigar-holder with wool would make smoking such hard labour that most men would prefer to forego the pleasure, whilst we fear that the admirable qualities of perchloride of iron do not include that of enhancing the flavour of the finest Havannas. A mouthful of "juice" from a pipe or cigar-holder is sufficiently distasteful without adding thereto the astringent properties of "steel drops." After all, our German friend comes late into the field, for the plan of filtering cigar smoke through a pledget of cotton-wool is as old as the hills. If the wool be lightly packed it may be not intolerable to the inveterate cigar-smoker—poor man!—who has been constrained to cut down his daily allowance—may we say a second time?—poor man!

#### Poplar Workhouse Scandal.

POPLAR Workhouse has long earned an unenviable reputation on account of the maladministration of its lunacy wards. Time after time in the columns of THE MEDICAL PRESS AND CIRCULAR have we called attention to the revelations of incompetency and inadequacy made at inquests. Again and again have we called for a Local Government Board inquiry into the administration of Poplar Workhouse Infirmary, especially as to the quality of the sick nursing and of the attendance and management of the lunatic ward. The latest inquest at Poplar Workhouse shows a laxity of administration that would not be tolerated by public opinion anywhere outside great, overgrown, callous London. From the evidence given before the Coroner on September 3rd, it seems that a paralysed man of thirty-seven was set to clean windows. He fell from some steps, became unconscious,

and was forthwith taken to the padded room and given a dose of salts by an attendant. Death was certified to be due to rupture of a blood-vessel in the brain. This picture is surely painful enough to attract the attention of the Local Government Board. First a partially disabled inmate is put to dangerous and absolutely unsuitable work. He receives a fatal head injury, and while unconscious is carried not to a ward but to a padded room, and salts are administered to him by an attendant. We should like to know by whose orders he was (1) set to window cleaning; (2) taken to a padded room; (3) dosed with salts. What have the Inspectors of that Board to say about the padded room and the single attendant in the lunatic ward? These facts have been brought to their notice by former inquests. In the public interest an accurate list of inquests held in Poplar Workhouse and resulting in censure by juries would be of advantage. Meanwhile, a searching Local Government Board inquiry is, in our opinion, imperative.

## PERSONAL.

THE King has presented his Marienbad physician, Dr. Ott, with a coloured portrait of himself in the uniform of an Austrian General.

SIR RENNELL RODD'S probable succession to the Embassy at Rome has recalled his mission to King Menelik of Abyssinia in the Diamond Jubilee year. The average height of the members of that mission was well over six feet, and that of Dr. Pinchin, the medical officer, was no less than six feet seven inches, while two others reached six feet four inches.

DR. HEGER was President of the International Congress of Physiologists held at Brussels last week, in the absence of Sir Michael Foster, M.P.

DR. G. B. MASON has been gazetted Surgeon-Lieutenant of the Mounted Infantry Company of the Antigua Defence Force.

It is officially announced that Dr. S. J. Steward has been appointed a supernumerary Government Medical Officer of Trinidad, West Indies.

DR. J. A. PICKELS, Medical Officer of Lagos, has arrived in England on leave of absence.

CAPT. A. E. HAMERTON, R.A.M.C., and Capt. C. Hudson, I.M.S., are mentioned in dispatches from Somaliland as having done particularly valuable work.

THE Principal Medical Officer has also brought to notice the merits of Capt. S. de C. O'Grady, R.A.M.C., Capt. F. L. Blenkinsop, I.M.S., and Major F. W. Gee, I.M.S., who are accordingly mentioned in the Somaliland dispatches.

AMONG non-commissioned officers appears the name of Corporal D. Watt, R.A.M.C.

ON the 2nd instant, Miss Blanche Julia Cripps, elder daughter of the well-known surgeon, Mr. William Harrison Cripps, F.R.C.S., of 2, Stratford Place, London, W., and Abbotsford, N.B., was married to Mr. T. Jefferson Faulder, house surgeon at St. Bartholomew's Hospital.

THE Winter Session of Charing Cross Hospital Medical School will commence on Monday, October 3rd, by the delivery of the fifth Biennial Huxley Lecture by Sir William MacEwen, F.R.S., and the Old Students

Dinner will be held on the same evening at the Hotel Métropole.

SIR THOMAS STEVENSON will open the Winter Session of Guy's Hospital Medical School on Monday, October 3rd. A House Dinner will be held the same evening in the College Dining Hall at 7.30 p.m.

THE Winter Session at King's College, London, will begin on Tuesday, October 4th, with an introductory address at 3.30 p.m. by Dr. Thomas Buzzard. In the evening the Old Students' Dinner will be held at the Hotel Cecil at 7 p.m., Dr. Urban Pritchard in the chair.

DR. PERCY KIDD will take the chair at the annual dinner of the London Hospital Medical School, in the College Library, on October 3rd, at 6.30 for 7 p.m., the Winter Session opening the same day.

AT St. Mary's Hospital Medical School the Winter Session will begin on Monday, October 3rd, with an introductory address by Dr. A. E. Wright. The annual dinner will be held at the Whitehall Rooms, Hotel Métropole, on the same evening, Mr. A. Q. Silcock in the chair.

THE annual dinner of past and present students of the Middlesex Hospital will take place on October 3rd, at 7 o'clock, at the Trocadero Restaurant, Dr. Sidney Coupland in the chair. The Winter Session will open on the same date.

THE Winter Session of the Medical Faculty of University College, London, will commence on Monday, October 3rd, with an introductory lecture by Professor J. Norman Collie, Ph.D., F.R.S. The Old Students' Dinner will be held the same evening, at the Hotel Cecil, when the chair will be taken by Mr. John Tweedy, President of the Royal College of Surgeons.

WESTMINSTER HOSPITAL MEDICAL SCHOOL will open on Monday, October 3rd. The annual dinner will take place on the same evening at the Trocadero Restaurant, when the chair will be taken by Dr. W. Rivers Pollock.

ARTHUR THOMSON, M.A.Oxon., M.B.Edin., Professor of Human Anatomy and Regius Professor of Medicine, has been elected a member of the General Medical Council for a period of five years.

SIR ISAMBARD OWEN has been appointed a Governor of the Welsh University of Aberystwyth.

It is announced that Dr. Jameson will return shortly to the Cape, although he has not regained his usual state of health.

DR. FREDERICK NEEDHAM, Commissioner in Lunacy, and ex-President of the Medico-Psychological Association, has been appointed a member of the Royal Commission of Inquiry into existing methods of treating persons of defective mind not certified under the Lunacy Laws.

DR. OTT has been authorised to make the following statement to Reuter's representative regarding his Majesty's cure:—"The King has obtained this year excellent results from his visit and cure in Marienbad. While his Majesty had come in very good health, the cure has had very beneficial effects, and the King leaves Marienbad in the most perfect health in every respect, and declares that he never felt better in his life. The waters, the baths, the exercise, and the diet have agreed wonderfully well with his Majesty, and his sleep is as sound as possible. The King has lost just the proper amount of weight, a fact which is clearly evident in his light and easy step. His Majesty will undergo a slight after-cure for ten days or a fortnight, consisting merely in taking a small quantity

of Marienbad salts. His Majesty has expressed his entire satisfaction with the results of his cure at Marienbad."

### Special Correspondence.

[FROM OUR SPECIAL CORRESPONDENTS.]

#### SCOTLAND.

STATE REGISTRATION OF NURSES.—Miss Isla Stewart, Matron of St. Bartholomew's Hospital, delivered an address on this topic in Edinburgh last week. She said that the prevailing state of affairs was unfair to the public, and also to the trained nurses who had to compete with the half-trained. Two Bills for the registration of nurses were at present before Parliament—one by the State solely for the registration of nurses, and the other by the Royal British Nursing Association. Both Bills provide for a Central Council, whose importance could not be over estimated. In the former Bill the Council would be composed chiefly of nurses elected by and responsible to the body of nurses whom they represented. The institution of public examinations, and the granting of certificates to successful candidates would ensure a minimum standard of technical efficiency. Power was also given to the Council to remove the names of nurses who prove unworthy from the Register. This is the first time that the subject of registration of nurses has been brought prominently before the notice of the public in Scotland, and it cannot be said that hitherto the profession have displayed any great interest in the matter. The meeting was not largely attended, and few of the general public or medical profession were present—to some extent, no doubt, owing to the comparative emptiness of the city at the holiday season.

#### BELFAST.

THE DISTRICT LUNATIC ASYLUM.—The annual report of this institution, just issued by the medical superintendent, Dr. W. Graham, contains a number of matters of interest. The average daily number of patients under treatment was 1,021, and the admissions during the year were 254, a reduction of 13 as compared with the previous year. The cost of provisions was £8 9s. 9d. per head, and the total cost £23 9s. 10d. per head. After deducting receipts from pay patients, profits from the farm, and Government grants, the cost to the city is £13 14s. 5d. per head. Of the 254 cases admitted, hereditary influence is assigned as the probable cause in 29, but, as Dr. Graham points out, these figures are not worth much when we consider the well-known reluctance of families to admit such a cause. As one of the contributory causes to the recent increase in the number of cases, Dr. Graham lays some stress on changes in the dietary of the people. As he says, the labourer and artisan used to make porridge, milk, and potatoes, with an occasional piece of fish, their staple food. Now they use quantities of Indian tea (which they often boil), and stout, and all sorts of cheap tinned foods.

The most remarkable point is the increase of general paralysis of the insane—18 males and one female having been admitted during the year. In the four years 1894-97 there were nine cases admitted, and in the same number of years 1900-03 there were 57 admissions suffering from this disease. Taking this as his text, Dr. Graham gives a very vigorous little sermon on the necessity which he thinks exists for better teaching in matters of morals and hygiene.

THE SMALL-POX OUTBREAK.—A few fresh cases continue to crop up each week in various parts of Ulster, though as a whole the outbreak is certainly dying out. One case was discovered in Belfast last week, and removed to the hospital at Purdysburn. A bad case was admitted to the fever hospital at Irvestown, co. Fermanagh, and died in a few days. Practically all the inhabitants have been re-vaccinated. One case was admitted to Clones fever hospital

last week, and there, too, re-vaccination is general. There are five cases in Cavan fever hospital.

CHAIR OF PATHOLOGY IN QUEEN'S COLLEGE, BELFAST.—A petition has been drawn up and circulated for signature among the members of the hospital staffs in Belfast, in favour of the candidature of Dr. Thomas Houston for this chair. This petition is addressed to the President of Queen's College, and as it has been signed by practically every hospital man in the city, it can hardly fail to carry weight. As has been pointed out, the Chair of Pathology differs from all other chairs in this, that it is a matter of direct moment to the members of the medical profession in the district as to who its occupant is, for they must come into almost daily relation with him in making pathological examinations. Dr. Houston is a man so thoroughly qualified to fill the vacant chair, and such a favourite with the profession generally that the feeling in his favour is very strong. For the purely scientific chairs much may be said for appointing the best-qualified man without respect to local feeling, but in a chair whose occupant is in such intimate relations with the local men in practical work it is felt that a well-qualified local candidate deserves special consideration.

### Correspondence.

[We do not hold ourselves responsible for the opinions of our Correspondents.]

#### THE DIMINISHING BIRTH-RATE.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Dr. Taylor answers, in your last issue, not my letter of August 10th, but my case as pressed on his consideration by "Qualified Assistant." What answer has he given to my query whether, I, a struggling country practitioner, being married, ought to bring into the world an unlimited family? In the most pleasant but 'evasive way Dr. Taylor intimates he has not sufficient grounds to say if I was justified in getting married. That is not the point. Rightly or wrongly, I am married (to a charming gentlewoman, by the way). Ought I to follow Dr. Taylor's proposition and thereby court inevitable starvation in our small home? His general law applies to all married folk, and must, if true, be of universal application. Therefore, I ask Dr. Taylor once more if, with the income of a well-to-do artisan, but with the necessary outward show of a well-to-do member of the middle classes, I am morally constrained to produce an unlimited progeny? Finally, is continence—the highest form of restriction—to be banned as well as methods or artificial prevention? A writer who lays down the law in so decisive a way as Dr. Taylor can surely explain details of application.

I am, Sir, yours truly,

A COUNTRY PRACTITIONER.

Bucks, September 1st, 1904.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—I must express my cordial thanks to Dr. Taylor for his courteous reply to my letter; I am much indebted to him for so kindly dealing with the specific points I raised. But I cannot say that to my mind the difficulty is solved. In the first place I think it is a pity Dr. Taylor avoided a direct reply to the question whether our friends the country doctor and the poor curate did right to marry. No doubt there were many factors to be considered in their cases, but I hoped the issue would be narrowed down to the single point whether a professional man with an income of say, £150 or £200 a year profit, little reasonable prospect of increase, and no expectations should consider himself debarred from the comfort that a good wife would bring to his home, because he absolutely could not afford an unlimited family. Our country practitioner is, let us assume, a well-educated man, pursuing a life of hardship and self-sacrifice for the benefit of his fellow creatures. His home is his only pleasure. Is he to have what every labourer in the country looks to have—a help-

meet and stay, or to be dependent on the caprices of some elderly village body who will come in and "do for" him? And our poor curate, without the least disparagement to him, I can only say that perhaps the greatest benefit of the Reformation lay in abolishing celibacy for the clergy. Dr. Taylor will appreciate what I mean.

"Two wrongs will not make a right." Paraphrased this means—Because society forbids you to be natural, you are wrong in being unnatural. It is a choice of unnaturalnesses. The sexual instinct is natural; you must either abstain, which is unnatural, or take artificial precautions, which is unnatural. You are in a dilemma. The only way out is to marry and abstain, which is probably the most unnatural, as well as the most impracticable.

To young men like myself who look forward to an opening in the near future, bachelorhood is regarded merely as a temporary penalty that one pays for having been born in a certain social stratum, but one cannot be blind to the fact that some day the question of providing for more children than one can afford may present itself in concrete form. I cannot hope that Dr. Taylor's practical philanthropist will have put the world into joint by that time, and I fear it will be but cold comfort I should derive from contemplating how much longer it would be before the hardness of my lot forced an alteration in the economic conditions of the country. All of us have not a Horace's capacity for suiting circumstances to ourselves, and are compelled to suit ourselves to circumstances.

I am, Sir, yours truly,  
QUALIFIED ASSISTANT.

Glasgow, September 3rd, 1904.

#### THE LUNACY QUESTION.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Some years ago there was a discussion at one of the London Medical Societies which was rather amusing. I remember hearing the late Sir Wm. Gull assert that it was easier to calculate the distance between the sun and our earth than explain the phenomena of insanity; in fact, that it was a great deal more difficult to understand the aberrations of the brain than those which astronomy has to consider. Very few at first agreed with Sir William and the specialists in insanity did certainly not agree with him.

Sir William, however, had far the best of them in the discussion, and most of those who heard him came away with the impression that he was right in his views, and that insanity is an incomprehensible matter, and cannot be dealt with in the same way as most maladies of the human system.

To try and define insanity is like trying to define most negatives, and it would be well to define sanity first before dealing with the negative.

It would be well if a law were passed that practitioners should be required to report to some central authority all cases that they attend or advise upon, if in any such cases the mind of the patient is so disturbed or deranged as to require special care to be observed by those in charge of the case, lest any injury might be caused by the patient to himself or others in any way, or the patient might suffer from improper influence personally or in any other way, that is, in respect to disposal of property, &c., &c.

I hope that THE MEDICAL PRESS AND CIRCULAR will assist the Commission appointed to deal with this subject,

I am, Sir, yours truly,  
ROBERT J. LEE.

West Kensington, Sept 5th, 1904.

#### THE POSITION OF MEDICAL OFFICERS OF HEALTH.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—The *Times* has recently published an able and comprehensive account of the Report of the Committee on Physical Deterioration, and a leading article upon it. In this article the difficulty of the position of

medical officers of health is, among other things, discussed. The article points out that the provision of the Act of 1872, by which the post of medical officer of health is created, has been virtually neutralised in many places by the fact that the officer is the servant of a body of men, many of whom obtain seats upon local authorities with the purpose of placing difficulties in the way of active sanitary administration. Enforcement of sanitary laws is not compulsory, and the Local Government Board has no power to coerce the Authority. The medical officer may remonstrate in private when flagrant neglect of duty is displayed, but it is as much as his place is worth to make any public protest or to set himself in open antagonism to his employers. He knows very well that when the Authority is dominated by men of a certain type it is because there exists no public opinion to which an appeal can be effectually made, and that such an appeal would surely lead sooner or later to loss of his position. In most cases the officer, recognising that there is no remedy, is forced to restrict himself within a very limited sphere of activity, much as he may regret and deplore it. In many municipalities, especially in the smaller towns when tradesmen and owners of slum property dominate the Authority, the model bye-laws of the Local Government Board, although adopted in their entirety, are enforced only in so far as they do not interfere with the interests of landlords; the sanitary inspector's department is undermanned and unprovided with disinfecting or even drain-testing apparatus; slum dwellings, displaying all the worst forms of insanitary conditions and over-crowding, abound, whilst in many places no provision is made for isolation of any form of infectious disease, and the Food Adulteration Acts are simply ignored. As the *Times* points out, it is in boroughs where local administration presents this character that the inspectors of the Local Government Board are so often engaged in investigating the causes of outbreaks of disease, and where, after tracing this or that epidemic to its origin they as constantly report that the whole inquiry was but a repetition of one conducted in the same place a few years previously, and that the overcrowding, or the water contamination, or the slum dwellings, to which the attention of the locality was directed on the former occasion, have remained unaltered, if not aggravated by increase of population. Towards remedy of these abuses the Committee on Deterioration recommend that the post of medical officer of health should be made permanent, so that the officer should not be liable to dismissal by the Authority when striving to carry out his duty conscientiously. The *Times* seems to think that such a reform would put an end to the evils it exposes. It avows that modern sanitary legislation "has been practically inoperative in the very places in which it was most required, and has left large sections of the population to live and grow under every conceivable moral and physical disadvantage, while the ratepayers themselves are absolutely without any remedy against their 'representatives.'" No doubt some good would be done by giving the medical officer of health security in his position; but as the Authority would still fix the amount of his remuneration and control its increase when deserved, it is easy to see how uncomfortable the position of an uncompliant man might be made, and how far from independent he must remain. What is most remarkable is the *Times'* suggestion that the ratepayers have no remedy. Their remedy, and the only complete remedy for the abuses which exist more or less throughout the country, is to turn out inferior members of local authorities and replace them by men really imbued with public spirit and not capable of sacrificing the welfare of their poorer fellow-citizens in pursuit of selfish, mean, and sordid ends. This remedy is in the hands of the ratepayers. It is their fault and their shame that it is not applied. The great bulk of the public know little and seem to care less about local government; men of intellect and position refuse to take any part in it; they will not offer themselves as candidates for local boards, nor take active steps in putting fit men on. Even in London not more than

40 per cent. of the burghesses could be induced to vote at the last County Council election, and there prevails an equal lack of local patriotism in this regard throughout the country. Democratic institutions cannot be administered to full advantage unless all intelligent citizens take a due interest in their working. The existing apathy forms a danger to the nation. Rather than allow the present state of things to continue, it would almost be better to revert to bureaucracy and put the whole of the sanitary administration of the nation into the hands of the Local Government Board. The proposed change in the status of the medical officer of health would be a move in that direction; but by diminishing the responsibility of the local authorities, and encouraging the indifference of responsible citizens whose duty it is to guard the interests of the community to which they belong, it would, it seems to me, do even more harm than good to the cause of real reform and advancement.

I am, Sir, yours truly,  
AN ACTIVE SANITARIAN.

### Obituary.

#### INSPECTOR-GENERAL OF FLEETS DUGALD MACEWAN, M.D., R.N.

WE regret to announce the death of Inspector-General Dugald MacEwan, M.D., R.N., at his residence in Bedford, at the age of seventy-eight years. Dr. MacEwan was a native of Lochgilphead, Argyllshire, and he entered the Royal Navy as Surgeon in 1847, became Staff Surgeon in April, 1856, Fleet Surgeon in 1875, Deputy Inspector-General of Hospitals and Fleets in January, 1882, and Inspector-General in January, 1887. He served in China, the East Indies, and Burma, in the Baltic throughout the Russian War, and was present at the bombardment of Sweaborg and Hango, in South America. His decorations included the Burmese and (Russian) Baltic medal, and the Jubilee and Coronation medals. He was awarded the "Sir Gilbert Blanc" medal, and was Honorary Physician to the King and to the late Queen Victoria. At the time of his retirement in 1887 he had for seventeen years been in attendance when her Majesty was travelling on board the Royal yacht, *Victoria and Albert*. He is survived by his widow, four sons, and three daughters.

#### SURGEON-MAJOR JOHN CAMPBELL, C.B., M.D., R.A.M.C.

SURGEON-MAJOR JOHN CAMPBELL, C.B., M.D., late Indian Army, who died on Friday last at Looe, Cornwall, was born in 1817. He was the youngest son of the late Captain Thomas Campbell, R.N., and served in the Afghan War of 1841, in Scinde in 1843, and in the Indian Mutiny in 1857. He was decorated for the services which he rendered during the siege of Lucknow.

### Literature.

#### TAYLOR ON APPLIED ANATOMY. (1)

MR. TAYLOR'S book is undoubtedly one of the most interesting works dealing with anatomy published within recent years. The plan of the book, which the author rightly describes in the preface as "*surgery from the anatomical standpoint*," is excellent. The arrangement of the material and the manner in which it is presented enables the reader to find in the shortest possible time the information which he seeks. The various regions of the body are each first dealt with in a short anatomical description—the more minute details being given in smaller type—and then the bearing of a knowledge of the anatomical facts upon the pathology of the part, and upon the diagnosis and treatment of its morbid conditions, is graphically explained.

This method of presenting anatomical facts and details is undoubtedly one which will excite and hold the interest of the reader.

(1) "A Treatise on Applied Anatomy." By Edward H. Taylor, M.D., F.R.C.S. L., Surgeon to Sir P. Dun's Hospital, Dublin; Examiner in Applied Anatomy, Trinity College, Dublin. Pp. xxvii and 788. With 178 figures and plates, many in colours. London: Charles Griffin and Co. 1904.

The importance of an accurate knowledge of anatomy in surgical work can hardly be over-estimated, and since it is not merely a knowledge of isolated applied facts which is essential, we feel that the author has done well in introducing into his descriptions an accuracy and an amount of anatomical detail often found lacking in works on applied anatomy. In the progress of medicine, surgery and pathology anatomical and embryological observations and discoveries, at first merely of scientific interest, are ever proving themselves of the greatest importance in elucidating and explaining morbid conditions, or in enabling physicians and surgeons to arrive at correct diagnoses and devise new forms of treatment. It is indeed quite useless to attempt sharply to separate the points which are of practical from those of pure theoretical importance in anatomy. The subject is, however, so vast that all parts cannot be treated equally, and selection is, therefore, necessary. We believe that in making his selection Mr. Taylor has been most successful, and that he has produced a work which will be not only of the greatest use to surgeons, but will also prove itself a stimulus to students of anatomy by indicating to them the manner in which a knowledge of this subject is of the highest importance in explaining and elucidating the subjects studied in the later years of the medical curriculum.

In a short notice it would be quite impossible to call attention to the many excellent points presented by the work, but we must not fail to mention the many beautiful illustrations drawn from specially prepared dissections. These are the work of Mr. J. Murray, and are a special feature of the book—indeed, many of them are among the most beautiful anatomical pictures that we know.

Perhaps the most interesting of these figures are those illustrating the relationships of the parts connected with the organ of hearing to the base of the skull, those exhibiting the firm connections and relations of the stomach, and those dealing with the surgery of the rectum.

The general impression left by a survey of Mr. Taylor's book is that it is the right kind of work to place in the hands of the best type of medical student in his final years.

#### BISHOP ON ESSENTIALS OF PELVIC DIAGNOSIS. (a)

THE design of this book is to assist those who have little practical acquaintance with pelvic diagnosis, but whose general training is such as enables them to pick out the salient symptoms of a particular case. Elaborate tables, evidently very carefully considered, have been constructed with the object of conducting the inquirer along settled routes to a definite opinion as to the true nature of the disease which lies at the root of these overt symptoms and signs.

In a fair preface there is, what seems to us, a just appreciation both of the difficulties, dangers, and objections to the making of such a book. We quite agree that as to the value of such each one must judge for himself. But it is undeniable that such a book as this presupposes the existence of very grave gaps in clinical education—of lacunæ which, if often found, could hardly be filled in or bridged by the most elaborately compiled tables. Indeed, while we admire the completeness of these "aids to diagnosis," we question whether their very accuracy and completeness would not prove the most effectual bar to their usefulness. Assuredly, the average text-book would better serve the wants of the average man. The main objection would seem to lie in the very difficulty of utilising the methods. Those who most require assistance are exactly those least fitted to avail themselves of so complex a scheme. We incline to believe that this book will be most liked where least needed.

(a) "The Essentials of Pelvic Diagnosis, with Illustrative Cases." By E. Stanmore Bishop, F.R.C.S., Hon. Surgeon, Ancoats Hospital, Manchester, &c.; and an Appendix on Examination of the Blood, &c. By C. H. Melland, M.D., Hon. Physician, Ancoats Hospital, Bristol; John Wright and Co. London: Simpkin, Marshall, and Co., Ltd.

Perhaps the foregoing general observations do scant justice to the plan of the work. Properly to understand this the Introductory Chapters should be read. These are followed by a few chapters on general methods of examination, these by a particularly interesting discussion of pain as a diagnostic factor in pelvic disease.

The Appendix (Examination of Blood) seems a somewhat needless addition to the work.

#### GALABIN ON DISEASES OF WOMEN. (a)

THE sixth edition of this well-known manual, which we have often favourably noticed in its earlier editions, hardly calls for detailed criticism.

Most of the new material concerns operative technique, and a notable addition and improvement is to be found in Chapter 14, which is devoted to Diseases of the Urethra and Bladder. Such a chapter is indeed inevitably needed in any modern work upon gynaecology.

There are many new illustrations, though we cannot specially commend the illustrations as a whole. The micro-photographs, also a new feature, and twenty-five in number, might in the greater number of cases have been omitted. Take, for example, Fig. 82, which purports to show in section the mucous membrane of a uterus removed by hysterectomy on the first day of menstruation. But there is here no emphasis of the characteristic details—only just enough for a specialist to rely upon. Why not append a description to each micro-photograph which would draw attention to noteworthy points; and why not also give—as is done in some cases—the magnification, or still better a statement of the glasses—eye-pieces and objectives—used. The popularity of the book has been proved and is deserved. It is essentially practical in its scope; and its teaching is clear and unambiguous.

#### CRILE ON BLOOD PRESSURE IN SURGERY. (b)

IT is a considerable time since we have read a work of such interest and of so great practical importance as is the volume before us, containing the account of the researches made by Dr. Crile into causes of altered blood pressure and the deductions which he has been able to draw from these researches. We may say at once that the work he has done appears to us to be of the very greatest value, and to have well deserved the Cartwright Prize which it obtained.

The first 260 pages of the book are occupied by the statistics of 251 experiments made on animals. There is, of course, in this part, a large amount of repetition, but as the experiments were most costly in time and trouble, it was considered well to have a full account of them placed on record. The last 150 pages are occupied with the summary of experimental data, and are of the greatest interest; but even if the busy surgeon has not the time necessary for their close study he will find an admirable *résumé* of Dr. Crile's conclusions in the last ten pages. Dr. Crile recognises that there are two different causes of death during surgical procedures—shock and collapse. Shock is an exhaustion of the vaso-motor centres, in which neither the heart-muscle, the cardiac centres, nor the respiration are other than secondarily affected. Collapse is due to a suspension of the function of the cardiac or of the vaso-motor mechanism, or to hæmorrhage. In the former, the exhaustion of the centres renders stimulants and strychnine of little value; indeed, the latter is, in the writer's opinion, dangerous. Saline infusion is also of slight or no use. On the other hand, adrenalin acts on the heart and the blood-vessels, and raises the blood pressure in every degree of shock, even when the medulla has been cocaineised and in the decapitated animal. It is, however, rapidly oxidised by the tissues and blood, and its effects are fleeting. It consequently must be given continuously, but also

with caution, as it possesses a power of markedly stimulating the cardio-inhibitory mechanism. In collapse, cardiac stimulants and strychnine are both of value as the vaso-motor centres are not exhausted. Saline infusion was also found to be of value. In shock, a contrivance called the pneumatic rubber suit, made with the object of providing an artificial peripheral resistance and so raising the blood pressure, acted successfully. By the combined use of artificial respiration, the infusion of adrenalin, and the application of the rubber suit, a patient who, from fatal injury to the brain, had been conventionally dead for nine minutes, was partially resuscitated for thirty-two minutes, during which time a strong heart beat was noted, and he was able to move his head. We strongly recommend the perusal of this work to our readers.

#### PHYSIOLOGY OF DIGESTION AND DIETETICS. a

THIS privately published but most interesting volume consists of a series of reprints of essays which, during the last nine years, Dr. Robertson has contributed to various journals. They deal principally with the digestion and value of saccharine foods in health and disease, and should prove of interest to the physiologist and of service to clinicians.

### Literary Notes and Gossip.

THE forthcoming publishing season promises to be unusually prolific in new medical books and new editions; it is currently reported that one London house alone has as many as thirty in the press.

\* \* \*

A "HOSPITAL Penny Fund," has been inaugurated by the Editor of our interesting weekly contemporary *Public Opinion*. In his forcible appeal for funds he remarks that the Hospital Sunday and Saturday Funds are but annual affairs, and the man in the street—too often, alas!—thinks he has done his duty if he increases his offering to the collection on that Sunday, or, perchance, puts a piece of silver in the box of the Saturday Fund collector. Correct statistics of those who do and do not give are, of course, difficult of attainment, but the Editor avers that there are 30,000,000 in Great Britain who never give one penny. If each of these gave but a penny, over £130,000 would be realised. The scheme is not to be confined to London alone; but will appeal to the provinces, to Scotland, Ireland, and Wales, and incentives to collection will be offered in the shape of prizes. This philanthropic effort has our heartiest wishes for success.

\* \* \*

DR. H. C. L. MORRIS has written a serviceable little book on "Bognor as a Health Resort."

\* \* \*

DR. R. HENSLÖWE WELLINGTON, Secretary of the Medico-Legal Society has just published a valuable monograph on "The Verdict of Suicide whilst Temporarily Insane."

\* \* \*

WE understand that Dr. Norman Moore is writing a history of St. Bartholomew's Hospital, which will shortly be issued by Messrs. Arthur Pearson & Co. Mr. Howard Penton has drawn some original illustrations for the book, which will also include reproductions of the ancient seals and monuments of the Hospital with many historical reminiscences. The proceeds of the sale of the work will be devoted to the rebuilding fund, and the list of subscribers to the first edition, limited to two thousand copies, will be printed as an appendix. Applications for copies should be addressed to the Honorary Secretary of the Rebuilding Fund, St. Bartholomew's Hospital, London.

\* \* \*

WE have received from Messrs. Mabie, Todd and Bard publishers, and manufacturers of the famous "Swan" Fountain Pens, a well-printed

(a) "Diseases of Women." By A. L. Galabin, M.D., F.R.C.P., late Fellow of Trinity College, Cambridge; Consulting Obstetric Physician, Guy's Hospital, &c. Sixth Edition, much enlarged. London: J. and A. Churchill, 1903.

(b) "Blood Pressure in Surgery. an Experimental and Clinical Research." By George W. Crile, A.M., M.D., Professor of Clinical Surgery, Western Reserve Medical College. London and Philadelphia: J. B. Lippincott and Co. 8vo, pp. 422. 1903.

(a) "Contributions to the Physiology of Digestion and Dietetics" By W. G. Aitchison Robertson, M.D., D.S.O., F.R.C.P.E., F.R.S.E. Edinburgh, 1903.

booklet of fifteen photographic views of the great International Exhibition now being held at St. Louis, which convey a striking impression of the immensity and beauty of the various structures. Messrs. Mabie, Todd, and Bard intimate that they will gladly send a copy of the book free to all readers mentioning this paper, who apply by post-card to them at 93, Cheapside, London, E.C., 95, Regent Street, London, W.; or 3, Exchange Street, Manchester.

WE learn from the editor in chief of the *Index Medicus* (second series), that a circular letter has been extensively distributed signed by the Directeur général de l'Institut de Bibliographie médicale de Paris, 93, Boulevard Saint Germain, in which it is stated that the *Index Medicus* ceased to appear after the issue of the number for January, 1904, and that its publication would probably not be resumed this year. This statement is incorrect, had the writer inquired of the Secretary of the Carnegie Institution, or of the Editor of the *Index Medicus*, he would have been saved making an unfounded and misleading assertion. Its origin is doubtless to be found in the fact that owing to "strikes" in the printing offices of Boston, in which city the journal is printed, the January number was delayed.

### Medical News.

#### Postal Workers' Sanatorium Scheme.

A RECENT conference of representatives of the different branches of the postal service was held in one of the committee-rooms at the General Post Office, London, to consider a proposal for providing sanatorium accommodation for postal employes by affiliation with the National Committee for the Establishment of Sanatoria for Workers Suffering from Tuberculosis. The chair was taken by Mr. J. Fitzgerald (treasurer of the Fawcett Association). Mr. C. H. Garland, in an explanatory statement, said it was proposed to elect a provisional committee to carry out the necessary preliminary arrangements in connection with the movement for securing a sufficient amount of accommodation in sanatoria for all the cases of consumption which were likely to occur among postal servants. The original idea was to establish a sanatorium for themselves exclusively. When, however, the project was launched for providing sanatorium accommodation for the whole of the workers of this country, it was thought desirable to associate themselves with it. The National Committee was formed under the auspices of the Hospital Saturday Fund, and its scheme would have the support of the working classes generally. By allying themselves with those identified with the wider movement they would have placed at their disposal a large amount of expert opinion and advice. The proposal of the National Committee was to erect a sanatorium by public subscriptions, and the beds were to be endowed by friendly societies, trade unions, and other organisations. The object of the postal movement was to create a fund in order to reserve for the use of postal employes in that sanatorium a certain number of beds. The Postmaster-General had practically given his consent to their scheme, which included a voluntary payment by members of the postal staffs of 2s. per annum. He was told by the chief medical officer of the Post Office that a subscription of 2s. a year would produce a sufficient sum to provide all the accommodation required for Post Office cases, and would probably leave a surplus to pay the travelling expenses of those coming from a distance. There was no intention on their part to appeal for subscriptions outside the postal staffs. There would be a public appeal made by the National Committee for funds with which to build the sanatorium. The beds would be under the control of the organisations which endowed them. He could not say definitely where the sanatorium would be erected, but negotiations were going on for the acquisition of a site about seventeen miles from Hastings. The more hopeful members of the National Committee considered that building operations would be started early next year, while others thought that they would

not be started till the middle of the year. The subscription of 2s. a year by postal workers would entitle them to accommodation at the sanatorium free of all charge, and in addition their sick pay would be continued for six months. After further discussion, a provisional committee was elected to carry out the necessary preliminary arrangements.

#### St. Thomas's Hospital House Appointments.

THE following have been appointed House Officers from yesterday (Tuesday), Sept. 6th.—*Resident House Physicians*: B. Higham, M.R.C.S., L.R.C.P.; W. Haward, M.B., B.S.Dur., M.R.C.S., L.R.C.P.; H. C. Lecky, M.A., M.B., B.Ch.Oxon. (extn.); C. H. Latham, M.R.C.S., L.R.C.P. (extn.). *House Physicians to Out-Patients*: A. G. Gibson, B.A., M.B., B.Ch.Oxon., B.Sc.Lond.; K. Takaki, M.R.C.S., L.R.C.P. *Resident House Surgeons*: H. S. Bennett, M.R.C.S., L.R.C.P.; N. C. Carver, B.A., B.C.Cantab., M.R.C.S., L.R.C.P.; A. C. Birt, M.R.C.S., L.R.C.P.; G. T. Birks, M.A., M.B., B.C.Cantab. *House Surgeons to Out-Patients*: H. A. Kisch, M.R.C.S., L.R.C.P.; G. R. Footner, B.A.Cantab., M.R.C.S., L.R.C.P.; R. E. G. Gray, M.A.Cantab., M.R.C.S., L.R.C.P.; J. C. F. D. Vaughan, M.R.C.S., L.R.C.P.; *Obstetric House Physicians*: Senior, J. P. Hedley, M.A., M.B., B.C.Cantab., M.R.C.S., L.R.C.P.; Junior, H. I. Pinches, M.A., M.B., B.Cantab., M.R.C.S., L.R.C.P. *Ophthalmic House Surgeons*: Senior, H. S. Stannus, M.B., Lond., M.R.C.S., L.R.C.P. *Throat Department*: T. B. Henderson, M.A., M.B., B.Ch.Oxon. R. E. Whitting, B.A., B.C.Cantab. *Skin Department*: W. L. Harnett, M.A., M.B., B.C.Cantab., M.R.C.S., L.R.C.P.; F. M. Bulley, B.A.Cantab., M.R.C.S., L.R.C.P. *Ear Department*: T. Guthrie, M.A., M.B., B.C.Cantab., M.R.C.S., L.R.C.P.

#### Idiots and Imbeciles.—A Royal Commission.

THE King has been pleased to appoint a Royal Commission to consider the existing methods of dealing with idiots and epileptics and with imbecile, feeble-minded or defective persons not certified under the Lunacy Laws, and to report as to the amendments in the law or other measures which should be adopted in respect of their care, training and control. The members of the commission are as follows: The Marquis of Bath (chairman); Mr. William Patrick Byrne, C.B.; Mr. Charles Hobhouse, M.P.; Dr. Frederick Needham; Mr. Henry David Greene, K.C., M.P. Mr. Charles E. H. Chadwyck-Heale, K.C.; Rev. Harold Nelson Burden; Mr. Willoughby H. Dickinson; Mr. Charles Stewart Loch; and Mrs. Pinsent. Dr. Needham is a Commissioner in Lunacy and an ex-president of the Medico-Psychological Association.

#### International Congress of Physiologists.

THE International Congress of Physiologists met on August 31st at the Solvay Institute in Brussels and will continue in a series of similar meetings to be held at Turin, Cambridge, Berne, and Basle. The President, Dr. Heger, in his opening address, expressed regret for the absence through reasons of health of the Honorary President, Sir Michael Foster, M.P. The proceedings of the congress are private.

#### Killed by Swallowing a Wasp.

A COACHMAN named Fisher, who worked for Mr. Compton Rickett, M.P. for Scarborough, has just died at his employer's country seat at East Hoathly, near Lewes, as the result of a wasp sting. He swallowed the insect with some beer, and his throat was so badly stung that he was suffocated.

#### Sanitary Institute.

THE thirty-eighth course of lectures and demonstrations for sanitary officers which will commence at the Sanitary Institute, Parke's Museum, London, on Monday, September 12th, will embrace lectures on Municipal Hygiene and on Meat and Food Inspection, including the taking of samples of water, food, and drugs for analysis, with practical demonstrations of meat inspection.

#### Liverpool Mortality.

THE death-rate in Liverpool, which for some weeks has been very high, reaching 39.2 per thousand per annum a fortnight ago, fell during the past week to 29 per thousand. The decrease is due to the cooler weather, and the consequent fall in diarrhoea mortality.

## Notices to Correspondents, Short Letters, &c.

**CORRESPONDENTS** requiring a reply in this column are particularly requested to make use of a *distinctive Signature or Initial*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

**ORIGINAL ARTICLES** or **LETTERS** intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

**CONTRIBUTORS** are kindly requested to send their communications, if resident in England or the Colonies, to the Editor at the London office; if resident in Ireland, to the Dublin office, in order to save time in re-forwarding from office to office. When sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

**REPRINTS**.—Reprints of articles appearing in this journal can be had at a reduced rate providing authors give notice to the publisher or printer before the type has been distributed. This should be done when returning proofs.

### LIFE INSURANCE QUERY.

F.R.C.P. writes in answer to query as to the proposal for life insurance from "O.F." in our last week's issue:—"This life may be insurable at hazardous rates in some offices. In that case it would be well for the medical examiner to state the case most clearly to the office, and to suggest a limitation of period covered by insurance. The non-recovery of applicant's weight, together with the low specific gravity of the urine, render the life undesirable from the insurance point of view. If the low specific gravity is permanent the case should, in my opinion, be rejected on any terms—this I suggest as a general view on data so far as available.—

Dr. E. N. P.—Antipyrine is credited with powerful anti-galactagogue properties and is sometimes employed to arrest the lacteal secretion. Under these circumstances it is by no means improbable that the administration of large doses of this antipyretic in cases of mild puerperal infection may explain the sudden cessation of the secretion in your patient. At the same time it has to be borne in mind that the secretion often ceases spontaneously, especially when there has been fever. In any case the administration of drugs of this class in puerperal infections is of much less therapeutical importance than measures aimed at removing the source of the infection.

### THE PRESERVATION OF RUBBER CATHETERS.

To the Editor of THE MEDICAL PRESS AND OBITUARY.

Sir,—In reply to the letter of your correspondent with reference to the "preservation of Rubber Catheters," we do not find that a good quality Red Rubber Catheter becomes "sticky" and swells after so short a use unless same has been treated with grease or oil in the place of glycerine. If this is the case the evil may be remedied by washing in warm water and soda immediately after use.

London, E.C., Sept. 2, 1904.

S. MAW, SON & SONS.

Mr. S. E. ATKINSON.—The report reached us as we were at press. We hope to utilise it in an early number.

Mr. B. BART.—We have seen it stated that such is the case but we have had no direct or official intimation of the fact.

S. E. V.—The Transactions of a Medical Congress are, so to speak, public property, and it is open to anyone to make use of them for literary purposes though it is customary and desirable in so doing to give the source of the information in order that readers may, if so disposed, verify their references.

Dr. Ross.—No, it would be decidedly improper for your correspondent to consent to attend a patient whose acquaintance he had made as deputy for a sick *colleague*, at any rate in respect of the particular illness.

### THE FREEDOM OF THE SOCIETY OF APOTHECARIES OF LONDON.

By an announcement in another column it will be seen that the governing body propose to admit ten members of the medical profession already holding the L.S.A. Diploma, to the freedom of the Society which we understand includes also the freedom of the city of London. Full particulars may be obtained on application to Mr. A. Mowbray Upton, Clerk to the Society, Apothecaries Hall, London.

Dr. HULFIELD (Malta).—The English Authorities do not recognise French degrees in our colonies, although facilities are offered for passing the Final Examinations to those possessing the degrees of a known university in France.

Mr. WARSON.—The latest information is being collected concerning the various Educational Institutions and will be published in *resumes* in our next number, including the query put by you.

Dr. J. E. HARBURY.—Communication to hand is hereby acknowledged.

### Vacancies.

Down District Lunatic Asylum, Downpatrick.—Junior Male Assistant Medical Officer. Salary £100 per annum, with furnished apartments, board, washing fuel, light, and attendance. Applications to the Resident Medical Superintendent.

Cardiff Union.—Assistant Medical Officer. Salary £130 per annum, with rations, apartments, attendance, and washing. Applications to Arthur J. Harris, Clerk, Union Offices, Queen's Chambers, Cardiff.

Resident Medical Officer for the Sanatorium for Consumptives at Eastby, near Skipton. Salary £100 per annum, with rations, apartments, and washing. Applications to George M. Crowther, Clerk to the Guardians, 22 Manor Row, Bradford.

London Open-air Sanatorium, Pinewood, near Wokingham, Berks.—Resident Assistant Medical Officer. Salary £100 a year, with board. Applications to the Secretary, London Open-air Sanatorium, 20 Hanover Square, W.

Rotherham Hospital and Dispensary.—Senior House Surgeon. Salary £110 per annum, with rooms, commons, and washing. Applications to the Secretary, E. S. Baylis, 19 Moorgate Street, Rotherham.

Metropolitan Hospital.—Casualty Officer. Salary £150 per annum. Applications to Charles E. Byers, Secretary.

Brighton, Hove, and Preston Dispensary (Northern Branch).—House Surgeon. Salary £160 per annum, with furnished rooms, coal, gas, and attendance. Applications to C. Somers Clarke, Hon. Secretary, 115 Queen's Road, Brighton.

Bath Royal United Hospital.—House Surgeon. Salary £80 per annum, with board, lodging, and washing. Applications to J. M. Sheppard, Secretary.

Birmingham General Dispensary.—Resident Surgeon. Salary £170 per annum, with furnished rooms, fire, lights, and attendance. Applications to Ernest W. Forrest, Secretary.

Township of Toxteth Park.—Resident Medical Officer. Salary £100 per annum, with board, washing, and apartments. Applications to J. Moulding, Clerk to the Guardians, 15 High Park Street, Liverpool.

Cheltenham General Hospital.—Assistant House Surgeon. Salary £92 per annum, with board, lodging, and washing. Applications to the Honorary Secretary, General Hospital, Cheltenham.

## Appointments.

ATTWOOD, RICHARD D. M.R.C.S., L.R.C.P.Lond., Second Assistant Medical Officer at the Southwark Infirmary.

BROSTER, W. B., M.B., C.M.Edin., Medical Officer of the White Lead Works, Burry Port.

## Births.

O'BRIEN.—On August 29th, at 29 Merrion Square, North, Dublin, the wife of C. M. O'Brien, M.D., of a son.

## Marriages.

FAULDER—CRIPPS.—On September 2nd, at the Marylebone Parish Church, London, Thomas Jefferson Faulder, son of the late E. B. Faulder, of Thursty, Carlisle, to Blanche Julie, elder daughter of W. Harrison Cripps, F.R.C.S., of 2 Stratford Place, London, W., and Abbotsford, Melrose, N.B.

GARRISH—JUDGE.—On September 3rd, at St. Giles's Church, Camberwell, Harold John Garrish, eldest son of J. T. Garrish, of Grove Lane, Denmark Hill, to Ethel Maud, daughter of E. W. W. Judge of Camberwell.

GOULD—PAPE.—On September 3rd, at St. Thomas's Telford Avenue, Stratham Hill, Valentine E. J. Gould, of Llanelly, son of J. E. Gould, M.D., of Bolton, to Maude Mary, only daughter of Geo. Pape, of Thornton Avenue, Streatham Hill.

LEADING—RICHARD.—On August 24th, Robert Craike Leaning, M.B., B.S., second son of the late Harry Leaning, Esq., of Chantry, Colchester, to Mary Gladys, youngest daughter of the late William Richards, Esq., of Talyceod, Monmouthshire.

WILSON—GRATTAN.—On Sept. 1st, Geoffrey Remington Wilson, M.A., M.B.Cantab., eldest son of Mr. Thomas Wilson, of Harpenden, Herts., to Eileen Margaret Georgina Grattan, youngest daughter of Dr. M. H. Grattan, of Ongar.

## Deaths.

BENNETT.—On September 2nd, at Amersham, Bucks, Ellen Selte Bennett, of 3 Marlborough Place, N.W., youngest daughter of the late Rev. Henry Page, and widow of the late Sir J. Eason Bennett, M.D., F.R.C.P.Lond., LL.D., F.R.S.

BURTON.—On September 2nd, at Southsea, Annie Margaret, widow of the late Rev. Richard Burton, of Alverstoke, and daughter of the late W. H. Allchin, surgeon, of East Malling, Kent, aged 76.

COCK.—On August 30th, at 147 Queen's Road, Peckham, Herbert Edgecombe, M.B.C.S., L.R.C.P., aged 33, eldest son of Dr. and Mrs. Cock.

COLLINGS.—On August 31st, at Spaxton Rectory, near Bridgwater, in her 84th year, Georgina, widow of the late Adolphus Collings, M.D., of Guernsey, and daughter of the late Honourable J. Nurse, of Ashbury, Barbados, West Indies.

CROSSMAN.—On September 1st, at White's Hill, Hambrook, Bristol, Edward Crossman, M.D. in his 72nd year.

WOODS.—On August 30th, at Inglewood, The Avenue, Bushey, Herts., Emily Rosamond Woods, daughter of the late Captain John Kulpe, formerly 5th Dragoon Guards, of Spring Hill, Borris in Ossory, Queen's County, Ireland, and widow of the late W. H. Woods, M.D., M.A., T.C.D., et Oxon, B.N., in her 82nd year.

No. II.

## EDUCATIONAL NUMBER, 1904—1905.

### INTRODUCTORY REMARKS.

THE choice of a future career is clearly one of the most momentous problems with which a young man can be faced. Its decision must be necessarily guided by many influences, some of them obvious enough, while others can be appreciated and explained only by wisdom acquired at the shrine of experience. The first great thing to be considered is whether the youth has any special aptitude or what is usually described as a "liking" for any one particular calling in life. Without such inclination it is to the last degree unwise for any person deliberately to embrace the study of the healing art. Of all the learned professions that of medicine demands the most affectionate and whole-hearted allegiance from her children. At the same time it is unhappily true that the ranks of medical practitioners contain many who have drifted into their occupation and who lack the enthusiasm that alone can lift them out of the rut of incompetency. Much the same, however, may be said of all intellectual pursuits.

As regards the material rewards of the profession of medicine the aspirant should recognise from the outset that the labourers are many and the harvest small. Any man who wishes to amass a fortune before he has attained middle age had better make up his mind to follow some business occupation. As a medical practitioner he will, in most instances be able to make enough to live upon within a short time of starting practice. Where there is much competition, however, he will find it hard to get much beyond that sum, and as a rule his increased income is swallowed up by greater proportionate expenses. A large general practice can be built up only by years of hard and conscientious work, at the end of which the practitioner will probably have amassed a moderate fortune. In all cases he will find it desirable to be provided with a sufficient sum of money either to buy a practice or to furnish a house and tide over the first years of waiting. Should he wish to enter the Public Health Service he will have to devote several years to acquiring a special knowledge of the duties to be performed in the office of a medical officer of health. Or he may prefer to enter the Army, Navy, or Indian Medical Services, which carry pay from the time of appointment and confer a pension upon retirement; latterly something has been done to render these Services more popular, but much remains to be done in that direction. Then there are lunacy, Poor-law, and Local Government Board appointments, some of them well-paid and highly responsible posts. Lastly, the medical student may have made up his mind to tread the honourable but thorny paths of the

consulting surgeon or physician, or of the specialist. In that case he must be provided with means to support him through ten years or more that will be required to enable him to make a livelihood. Many medical men whose names have become household words have had to endure many years of penury and self-denial. Indeed, no profession, not even excepting that of the barrister, could furnish more instances of hard living and high thinking than that met with in the ranks of consultant surgeons and physicians. On the other hand, the prizes to be gained in the higher branches of the profession are considerable, when tested by such acquisitions as social position, titles, honours, influence and substantial income. At the same time it must be borne in mind that not a few men of unblemished reputation and of great intellectual and professional acquirements live and die without having gained the favours of fortune. To succeed in these directions requires the possession of moderate means, average intellectual endowments, good education, a hospital appointment, a good address, and an iron resolution.

The rewards of medicine, then, are not to be measured by their bank value. Any medical man who conscientiously follows the practice of his profession, who is sympathetic to the suffering, who scorns delights and lives laborious days, and who makes "duty" and "responsibility" his watchwords, will most certainly rejoice in the esteem and consideration of his fellow citizens. The key to nine-tenths of the situation is admirably given in the aphorism which says that "Medicine is a wholly admirable profession, but for the most part not a good business."

There is in the study and practice of medicine ample scope for talents of the most varied kind. If, unfortunately, a tendency manifests itself in the daily practice of the healing art to fall into a routine, to treat disease by rule of thumb, that is the fault, or the defect, of the individual practitioner. The calling is one in which the individual practitioner is called upon to exercise independence of judgment, seeking in his own sphere to winnow the wheat from the chaff in the huge collection of principles, dogmas, and views bequeathed to us by our predecessors in the profession. We would impress upon every intending student that it lies with him to utilise the experience which will be his to assist in throwing light into dark corners—not so much by the publication of an occasional case of exceptional interest, but by endeavouring to deduce some general law, some vital principle, from the morbid phenomena which come under his notice. He should never forget that he is always a student—no longer a listener at compulsory lectures but perforce an observer, more-

or less thorough, more or less conscientious, of the working of Nature's laws, some of which we see as through a glass darkly, but of others we know little or nothing. Some epoch-marking discoveries have come from the ranks of the general practitioner, and assuredly it is never the material that is wanting.

#### THE CHOICE OF A SCHOOL.

The question of the choice of a medical school is often determined, so to speak, by accidents of time, place, and tradition. Many students nowadays go to one of the excellent provincial schools in their neighbourhood. Many others again, are attracted to the Universities, North or South of the Tweed, or across the Irish Channel, which grant the degree of M.D. without exacting an abnormally high standard of examination. Men who are receiving their general education at one of the universities will naturally enter the medical school attached to their Alma Mater, at any rate for a portion of the five years' medical curriculum. In some few instances the possession of a University qualification is made a *sine quâ non* in the holding of some coveted hospital or other professional appointment. There may be some sort of excuse for this species of organised "protection," which the labouring classes would call "trades-unionism," in the case of the professorships and examinerships in some of the ancient Universities. When a similar exclusion, however, is applied by medical charities the situation becomes intolerable. The fact remains, however, that in the majority of English hospitals and infirmaries none but London graduates and diplomates need apply. A newly formed association of Scotch Diplomates—many of whom are Englishmen and Irishmen—are calling attention to the unfairness of the conditions that exclude them from holding honorary appointments on the medical staffs of many English charities. These facts may possibly furnish useful hints to the intending student, who has to make the best of present conditions.

#### THE CHOICE OF QUALIFICATIONS.

No sooner has the study of medicine been entered upon than the student is called upon to define his aims; in other words, he has to decide through what portal he will enter the profession. The point is one of unquestionable importance, because there is no going back on the choice later in the student-career. The reorganisation of the University of London has rendered it possible for the average student to obtain a degree in medicine on terms less prohibitive than was formerly the case, but the fact remains that although the purely medical standard is attainable by any fairly diligent student, the matriculation examination and that in science nevertheless constitute serious stumbling blocks. The average student will probably find it more convenient to take the diplomas of the English Conjoint Board, and, should he deem a degree worth the extra trouble, he can put in attendance at one or other of the provincial Universities with the view of subsequently passing the examinations for the doctorate. Or he may choose to take a qualification or degree in the Scotch or the Irish schools, where education is sound, practical, and well-equipped, and the traditions of the teachers unrivalled. ■

#### THE COURSE OF STUDY.

It is unnecessary to discuss the details of the medical curriculum. We would, however, impress upon the student the importance of entering upon his work earnestly, with firm determination to familiarise himself with the subjects—*anatomy, physiology, and materia medica*—which constitute the threefold basis of practical medicine. And in respect of anatomy, the only valuable knowledge is that gained by actual

dissection of the dead body. Verbal descriptions and plates are only aids to knowledge, not knowledge itself. Dissection gives information at first hand—actual knowledge, not mere statements—and the practice of dissection is, in fact, a first course in surgery. We would warn the student against that form of intellectual laziness which consists in abandoning the dissecting-room in favour of the library. The latter course may enable the student to pass examinations, but it will never confer that intimate familiarity with the things themselves which is indispensable to success in practice. Nor should he despise that somewhat arid subject, *materia medica*. A knowledge of the physical properties of drugs and of their physiological action is all-important, to the hospital physician as to the general practitioner. Treatment is the ultimate object of all medicine, and the medicinal treatment of disease is still an integral part of the practice of medicine.

#### THE CLINICAL WORK.

It is in the wards and in the out-patient department, after all, that the student acquires most of his information concerning the course and treatment of disease. There he watches the daily progress of morbid processes, and learns the means employed to afford relief or to bring about recovery. It will be his privilege to unravel the tangled threads of each patient's life-history, and by the careful examination of data to arrive at a reasoned conclusion known as the diagnosis. In this way he will gradually learn to recognise the main principles which underlie the practice of medicine. Each patient who comes under his observation will, if properly studied, yield his quota of practical knowledge, and the value of the opportunity depends upon the ability and willingness of the student to avail himself thereof. The object and aim of clinical training is to cultivate the student's powers of direct observation and to train him to make correct deductions, and the habit of careful observation is one which should become second nature. The instruction received in the wards is incomplete unless supplemented by the lessons to be learned in the post-mortem room. There the student can follow the morbid process to its conclusion. The post-mortem room is the natural complement of the ward, and it is often only in this room that the clinical problem is unravelled and the student enabled to observe the organic lesions which determined the symptoms he has been studying. Incidentally the student should learn as much as he can of the method of carrying out these examinations, for it falls to the lot of most practitioners to have to make such examinations, and errors of observation or appreciation may be fraught with the gravest consequences to possibly innocent persons.

#### THE HIGHER QUALIFICATIONS.

There remains the question of the higher qualifications, *e.g.*, the Fellowships of the Royal Colleges, which are indispensable to those who contemplate a hospital career, either as physician or surgeon. The Fellowship of the London Royal College of Physicians is not obtained by examination, but by selection from among the members, but it is nevertheless demanded as a necessary qualification in the holding of many hospital appointments. Candidates for the membership are required to pass a searching examination and to satisfy certain other requirements before they can be admitted thereto, and subsequent elevation to the Fellowship is largely a matter of personal influence, though merit *per se* is not a bar to selection. The Fellowship of the Royal College of Surgeons, on the other hand, is a purely professional distinction, and is open to anyone who can pass the examinations. It is advisable to pass the

first examination for the Fellowship as soon as possible after passing the first membership, in order not to have to go over the ground later a second time. The Fellowships of the Scotch and Irish Colleges of Surgeons are conferred after examination, but are not recognised by the majority of large English medical charities.

#### CHOICE OF A CAREER.

For five long years at a minimum the student's ambitions do not soar beyond the boards of examiners. To obtain the right to practise is, for the time being, the object of his existence. When he has entered the portals of the profession he is confronted with the question of deciding in what particular path he shall direct his energies. Many neo-practitioners, not unwisely, spend a year or two in resident appointments at their own hospitals or at some provincial hospital or infirmary. Others acquire a knowledge of the practice, as distinguished from the theory, of medicine by serving as assistant or locum tenens. Others, again, either join their parents in practice or purchase partnerships. Then, too, there are the Services—Indian, Army, Navy, and Colonial—to choose from. The Poor-law Infirmarys provide each year a certain number of appointments, and these are the first rungs of the ladder which leads to the superintendency of these institutions. These posts are fairly remunerated, and afford reasonable security of tenure, but they entail much hard work, together with heavy responsibilities.

#### PUBLIC HEALTH SERVICE.

Every student who can afford the time is strongly advised to qualify in State Medicine, since this diploma renders its holder eligible for appointment as medical officer of health, and, moreover, the knowledge thus gained is invaluable in every department of practice. A diploma in State Medicine entails a special course of preparation and training subsequent to qualification, the conditions of which will be found under the appropriate heading. Although the tenure of office is not as yet on a satisfactory basis, there are many appointments of the kind which afford a free field for intelligent activity.

#### POST-GRADUATE INSTRUCTION.

Medicine has, of late years, become a field of vastly wider extent and when he enters upon his professional work the conscientious practitioner is apt to experience a painful sense of his shortcomings in many branches of medical practice. The knowledge which has been rendered available of recent years has obviously placed a peculiar responsibility upon the physician fresh from his studies. The desire so generally felt by men in practice to extend and complete their knowledge of special subjects has led to the organisation of post-graduate institutions on a large scale, of which advantage is freely taken by those who are fortunate enough to reside within accessible distance thereof. We would strongly urge senior students and young practitioners to avail themselves of every opportunity to acquire a working knowledge of the various special branches—eye, ear, throat, gynaecology, and so on. This leads us to the question of

#### SPECIALISM IN MEDICINE.

Hitherto the student has been taught that "the greatest mistake of all is to start in a speciality without being thoroughly grounded in general practice." Admitting that it behoves everyone, no matter what particular department of practice he may decide to adopt, to have acquired a thorough grounding in the general principles of medicine, it is impracticable for him to devote much time to a general practice. On the contrary, there is much to be said in favour of the view that it is best for the young practitioner to make his

choice at the earliest possible moment of the line of work which he designs to follow. As soon as he has qualified, therefore, or as soon after as may be, the intending specialist should endeavour to obtain a junior post in one or other of the special hospitals, where he can gradually work his way up.

#### MEDICAL PRACTICE IN FOREIGN COUNTRIES.

Practitioners qualified in Great Britain who desire to practise their profession abroad are still confronted with many difficulties. True, a step in the direction of reciprocity has been taken in the case of Italy, but elsewhere in Europe considerable difficulty will be experienced in obtaining permission to practise; indeed, with the one exception of Italy, it is usually necessary to go through the whole curriculum and pass the examinations in their entirety.

#### LONDON SCHOOLS.

**The Schools of Medicine in the Metropolis are the following, the scholarships, prizes, students' appointments, fees, &c., being set forth in connection with each place named. The names of the hospital staff, lectures, residential terms, and detailed information will be found, as a rule, in our advertisement columns.**

**ST. BARTHOLOMEW'S HOSPITAL.**—This hospital has 750 beds, and for many years past the school attached has had a larger number of entries than any other medical school in London. New laboratories have been specially equipped for the study of pathology, bacteriology, chemistry, and chemical pathology. Collegiate residence is here permissible, subject to the ordinary rules. The recreation ground for the use of students is at Winchmore Hill.

**Appointments.**—Ten house physicians and ten house surgeons are appointed annually. During the first six months of office they act as "junior" house physicians and house surgeons, and receive a salary of £25 a year. During their second six months they become "senior" house physicians and house surgeons, and are provided with rooms by the hospital authorities, and receive a salary of £80 a year. A resident midwifery assistant and an ophthalmic house surgeon are appointed every six months, and are provided with rooms and receive a salary of £80 a year. Two assistant anaesthetists are appointed annually, and receive salaries of £120 and £100 a year respectively. An extern midwifery assistant is appointed every three months, and receives a salary of £80 a year. Chief assistants and clinical assistants are appointed in each of the special departments. In-patient dressers, in-patient clinical clerks, clerks, and dressers to the assistant physicians, and to the physicians and surgeons in charge of special departments are appointed every three months without fee.

**Scholarships, &c.**—There are four open scholarships in science, £75, £75, £150, £50, tenable for one year, and a Jeaffreson exhibition, value £20; at the end of first year four junior scholarships of £30, £20, £25, £15, respectively; Treasurers' prize for practical anatomy; Foster prize in practical anatomy; senior scholarships, value £50, for anatomy, physiology, and chemistry; Wix prize, Hichens prize, Lawrence scholarship and gold medal, value 40 guineas, for medicine, surgery, and midwifery; two Brackenbury scholarships, of £39, in medicine and surgery; Bentley prize, for reports of surgical cases; the Kirkes gold medal for clinical medicine, with scholarship of £30. Shuter scholarship of £50; Skyunner prize of £15; Sir G. Burrows' prize of £10, and Matthews Duncan medal and prize, value about £20.

**Fees.**—By payment of an annual composition fee, a student is entitled to attend all the courses of instruction, and to hold the various clinical appointments. For students commencing their medical studies:—Entrance fee, 30 guineas; annual fee, 30 guineas, for five years. A student on qualification at the end of the five years is not liable for any further fees, and receives a perpetual ticket. Should he fail to qualify in this time,

the fee for further instruction is 10 guineas for each six months. Fees for University students:—Entrance fee, 20 guineas; 30 guineas annually for two years, and 10 guineas for each six months if not qualified. Fees for preliminary scientific students:—20 guineas; for laboratory instruction for D.P.H., 15 guineas.

The Warden, Mr. W. D. Harmer, will furnish further details on application.

**CHARING CROSS HOSPITAL.**—The school attached to this hospital is situated in central London, and contains new physiological, pathological, and bacteriological laboratories, materia medica and anatomical museums, an anatomical theatre, enlarged dissecting-room, and chemical theatre. The hospital and convalescent home contain 300 beds available for clinical study.

Clinical instruction is given in medicine, surgery, and obstetrics, and in the special department, diseases of the skin, diseases of children, mental disorders, the throat, the eye, nose and ear, and in the orthopædic, Röntgen, and electrical departments.

**Scholarships, Medals, &c.**—The Livingstone scholarship (100 guineas), the Huxley scholarship (55 guineas), and six other entrance scholarships, total value £550, are awarded annually. Two scholarships of the value of 72 guineas each are reserved for students of Oxford, Cambridge, or London Universities. All are awarded annually. Two Universities scholarships, value 72 guineas each, are open to students from the University of Oxford who have passed the 1st M.B., to students of the University of Cambridge who have passed the 2nd M.B., and to students of the University of London who have passed the intermediate examination in medicine. Candidates must give notice to the librarian of their intention to compete on or before September 24th, 1904. The Golding prize of £10 is open to students at the end of their first winter session. The Huxley medal, with prize of £10, is open to students at the end of their second winter session. The Pereira prize of £5 is open to all general students. The Llewellyn prize of £25 is awarded annually at the end of the curriculum. The Governors' Clinical Gold Medal is also open to students at the end of their curriculum, and a silver medal or its equivalent in books is awarded to the most distinguished student in each class.

**Appointments.**—The curator and pathologist is appointed annually, and receives £100 a year; medical and surgical registrars to the hospital receive £40 a year each, with luncheon in the hospital; obstetric registrar, six house physicians, six house surgeons, and two resident obstetrical officers are appointed each year; clinical clerks and dressers are appointed in all the general and special departments of the hospital.

**Fees.**—For the curriculum of study required by the various examining bodies and hospital practice, 115 guineas in one sum, or 126 guineas in five instalments.

The composition fee for sons of registered medical practitioners is 105 guineas, and the fee, by instalments, 115 guineas. For dental students, 55 guineas in one sum, or 61 guineas payable in two instalments of 31 and 30 guineas respectively.

**St. GEORGE'S HOSPITAL.**—This hospital is centrally situated in the West End, facing Hyde Park. It contains 356 beds, and special wards for ophthalmic cases and diseases of women.

**Appointments.**—Four house physicians and four house surgeons, entitled to reside and board in the hospital free of expense; four general assistants, four assistants in the special departments. Candidates for the above offices are selected quarterly by competition from among the perpetual pupils, sixteen pupils being in office at any one time. Obstetric assistant with a yearly salary at the rate of £50 and board and residence in the hospital; curator of the museum with a salary of £200; assistant curator with a salary of £100; two medical registrars, with salaries of £200 per annum; a surgical registrar with a salary of £200 per annum; an administrator of anæsthetics with a salary of £50 and two with salaries of £30 per annum; a surgery officer with a salary of £100 a year; two or more demonstrators of anatomy with a salary of £50 each;

and assistant demonstrators. All offices are open to candidates without additional fee.

**Exhibitions, &c.**—The Brown exhibitions, one of £100 per annum, tenable for two years, and open to perpetual pupils possessing a registrable diploma; and one of £40 per annum, tenable for three years and open to students of two years' standing or upwards, who at the time of competition have not been qualified to practise medicine and surgery for more than three years. The Brackenbury prizes of the value of £40 each, one each in medicine and surgery. The Webb prize in bacteriology, value £30. The Clarke good conduct and clinical work prize in surgery, the Thompson medal, the Brodie clinical prize in surgery, the Johnson prize in anatomy, the Pollock clinical prize in physiology, the Treasurer's prize for clinical reports, and four general proficiency prizes of ten guineas each.

**Scholarships.**—One in Arts, of £100. One in Science, of £100. Examination, September 20th. One of £50 in anatomy and physiology, open to students who have passed a recognised examination in anatomy and physiology.

**Fees.**—Composition fee for perpetual pupils, £150 or £160, in the following instalments: First year £50, second year £50, third year £40, fourth year £20. The fee for general subjects in dental surgery is £55, payable in two instalments: first year £30, second year £25. Only perpetual pupils can hold house office or compete for the Brown exhibitions.

**GUY'S HOSPITAL.**—This hospital is situated on the Surrey side of London Bridge, and contains 602 beds in constant occupation. There are special wards for ophthalmic and obstetric cases, eight beds in the latter being appropriated for difficult cases of labour. Some beds have also been set apart for diseases of the ear and throat, and an "isolation" ward for cases of infectious diseases arising in the hospital has been constructed. An obstetric registrar and tutor and an ophthalmic registrar and tutor are appointed to augment the teaching in the special departments, in addition to those attached to the general surgical and medical wards. Attached to the hospital is a large residential college with rooms for about sixty men, whilst for students who prefer to live in the suburbs, no other hospital is so conveniently placed, the railway accommodation being good and close at hand. There is a complete School of Dental Surgery at this Institution, which is recognised by the Royal College of Surgeons of England; the facilities thus afforded of completing the whole course of dental study within the walls of one hospital will be appreciated by those intending to practise dentistry.

**Appointments.**—Eight house surgeons, eight house physicians, eight assistant house physicians, twenty-four assistant house surgeons, eight obstetric residents, two ophthalmic house surgeons, twenty-four clinical assistants, and ninety-six dressers are selected annually from the students according to merit, and without payment. There are also a large number of junior appointments, every part of the hospital practice being systematically employed for instruction.

**Scholarships.**—Open scholarships of £100 and £50 in classics, mathematics, and modern languages. Open scholarships of £150 and £60 in chemistry, physics, and biology, and an open scholarship of £50 for University students in two of the following subjects:—Anatomy, physiology, organic chemistry, zoology, physics. The following are the scholarships, prizes, and medals open to students of the hospital:—The Arthur Durham prizes for dissection, £15 and £5; Junior prizes for general proficiency, £20, £15, £10; Hilton prize for dissection, £5; Michael Harris prize for anatomy, £10; Sands Cox scholarship for physiology, £15; Wooldridge prize for physiology, £10; Beaney prize in pathology, £34; Golding-Bird prize in bacteriology, gold medal and £20; Treasurer's gold medal in clinical medicine; Treasurer's gold medal in clinical surgery; Beaney studentship in materia medica (tenable for 3 years), annually £31 10s.; Gull studentship in pathology (tenable for 3 or 5 years), annually £150.

**New School Buildings.**—A considerable addition to the school buildings was made in 1897, comprising a

series of class-rooms, laboratories, and a lecture theatre for the teaching of physiology. In 1903 the magnificent Wills Library was opened, and a new museum for pathological specimens and additional lecture and class rooms are in course of erection.

**Fees.**—A new system for payment of composition fees has been recently instituted at this school. Particulars may be obtained on application to the Dean, Guy's Hospital, London Bridge, S.E.

**KING'S COLLEGE HOSPITAL.**—This hospital is centrally situated, being contiguous to the Royal College of Surgeons, Lincoln's Inn Fields. The College adjoins Somerset House and is close to the hospital, in which there are 220 beds available for clinical teaching; ophthalmic, ear, throat, skin, and dental departments are attached to the hospital. Some wards are specially devoted to children's diseases. The wards have been recently refloored and the electric light installed throughout.

**Scholarships.**—£800 are awarded annually in scholarships and prizes. At entrance, a science exhibition of £100 value is open to all candidates under the age of nineteen; two scholarships of the value of £100 each (subjects literary) are open to students commencing their curriculum. A scholarship, value £50, is open to students of a British University who come up to London to complete their curriculum; two junior scholarships of £20 each for first year students, one of £30 for second year students, one of £50 for third year students in residence, and one of £40 for fourth year students. In addition, students may compete for the Daniell scholarship, value £40; the Warnford prizes, value £40; the Rabbeth scholarship, value £20; the Carter, Todd, Jelf, Tanner, Leathes prizes, and all class and clinical prizes.

**Appointments.**—Medical and surgical Sambrooke regisrations, tenable for two years, each £50 per annum. Resident hospital appointments, *viz.*, senior and junior house physicians, assistant house physician, physician accoucheur's assistant and assistant house accoucheur, and three house surgeons with free board and residence at the hospital; and senior and junior clinical assistants in special departments.

**University of London.**—Special courses of lectures and practical instruction in the chemical, physical, physiological, and other laboratories have been arranged for students preparing for preliminary scientific intermediate science and other examinations of the University of London.

**F.R.C.S. Examinations.**—Special classes are arranged for the final F.R.C.S. examinations. Further particulars can be obtained from the Dean.

**LONDON HOSPITAL.**—This hospital is the largest in England, containing, as it does, 820 beds. It has, moreover, wards and a teaching staff for almost every special department in the domain of medicine; the scholarships and prizes are many and valuable, and both school and staff are deservedly popular with students.

**Appointments.**—The "House" appointments, which are numerous, are made without fee of any kind, and all resident officers are provided with free board and rooms, and in some instances with salary also.

The additional buildings for the department of public health, for the biological, chemical, and physical laboratories, *matéria medica* museum, &c., and the new bacteriological department with general laboratory, research laboratories, class rooms for D.P.H. work, sterilising room, animal room, &c., are now open.

**Fees.**—Perpetual fee for lectures, demonstrations, and hospital practice, payable in three instalments of 45, 45, and 40 guineas at the commencement of the first, second, and third years respectively, 130 guineas; or, if in one payment, 120 guineas. Fee for students entering in their third year (their first and second years having been spent at a recognised medical school elsewhere), 60 guineas. This fee is payable by students entering who have passed the first M.B. Oxford; the second M.B. Cambridge; or the Intermediate M.B. London. Dental students (general hospital practice and lectures), 40 guineas. General fee for dental practice, 10 guineas.

**Note.**—A reduction of 15 guineas will be allowed to the sons of medical men from the perpetual fee if paid in full, or 5 guineas from each instalment.

Special entries can be made either for single courses of lectures or for hospital practice.

Accommodation is obtainable at a very reasonable rate close by, or in the suburbs a few minutes' distant by train. Fuller particulars can be obtained of the Warden, Mr. Munro Scott.

**ST. MARY'S HOSPITAL.**—This hospital is situated at Paddington, near the terminus of the Great Western Railway, and at present contains 281 beds. Fresh laboratories, fitted with electric light and all modern improvements, for the study of pathology and bacteriology, have recently been added, and also a new physiological lecture-room. A special department of pathological chemistry has been instituted. The new wing, the ground-floor of which, comprising the new out-patient department, was opened in 1898, is now approaching completion; this will raise the number of beds to 350, and will include additional operating theatres, a new clinical laboratory, a clinical theatre, and an X-ray department.

**Appointments.**—All clinical appointments in the hospital are free to students of the Medical School, and the resident medical officers are chosen by competitive examination. Six house physicians, six house surgeons, four obstetric officers, and two resident anaesthetists are appointed in each year, and receive board and residence in the Hospital.

**Scholarships, &c.**—One scholarship in natural science, of the value of £145, open to any gentleman who has not completed a winter session of study at a medical school. One scholarship in natural science, of the value of £78 15s., and two of £52 10s., under the same conditions. Two scholarships, each of 60 guineas, open to students from any British University. The scholarships will be awarded by examination on September 20th and 21st.

**Fees.**—Fee for attendance on the full five years' curriculum of hospital practice and all lectures, demonstrations, and special tutorial classes, £140, paid in one sum on entering the school; or in instalments, £145.

Students who have completed their examinations in anatomy and physiology at the Universities of Oxford, Cambridge, or other University, are admitted as perpetual pupils on payment of a fee of 60 guineas in one sum, or 65 guineas in two annual instalments. University students, prior to completing the anatomy and physiology examinations, pay an annual fee of 25 guineas. After completing the anatomy and physiology examinations, the inclusive fee may be paid.

**Preliminary Scientific Course.**—Special classes, under recognised teachers of the university are held throughout the year.

**MIDDLESEX HOSPITAL.**—This hospital, which is conveniently situated in the centre both of business and residential London, contains 340 beds. There are special departments for cancer, and for ophthalmic, throat, aural, skin, dental, children's diseases, and electrical treatment (X-ray and Finsen light). Wards are also devoted to cases of uterine disease. The new school buildings are now in regular use. Residence for students is obtainable in the residential college, which has its frontage on the hospital garden.

**Appointments.**—Casualty surgical officer, casualty medical officer, six house surgeons, six house physicians, and two resident obstetric physicians. The above officers have residence and board in the college free of expense. Clinical clerks and dressers in all the departments are also appointed in addition to the foregoing.

**Scholarships, &c.**—Two entrance scholarships of the value of £100 and £60 respectively. One entrance scholarship of the value of £60, open to Oxford and Cambridge students only. (Subjects—Anatomy and physiology, including histology). "Emden" Cancer Research Scholarship, £100. "Richard Hollins," Research Scholarship, £105. Two Broderip scholarships of £60 and £40 respectively, for medicine and surgery; John Murray medal and scholarship, awarded every third year; the Governor's prize of £21

for students in their final year. Hetley clinical prize, value £25, awarded annually for proficiency in practical clinical medicine, surgery, and obstetrics; the Lyell Gold Medal in surgery and surgical anatomy; the Leopold Hudson prize, value 11 guineas, in surgical pathology, including bacteriology; Freeman scholarship, £30, in obstetrics and gynaecology; exhibitions of 10 guineas and 5 guineas for anatomy and physiology to second and first year's students respectively, as well as class prizes in all subjects.

**Fees.**—General fee for the entire course of hospital practice and lectures, 135 guineas, if paid in one sum on entrance, or by instalments of 60, 50, and 35 guineas, payable at the commencement of the first, second, and third year respectively. For those who have completed their anatomical and physiological studies the fee is 70 guineas on entrance, or in two instalments of 40 and 35 guineas. The composition fee for London University students is 145 guineas. For those who have passed the preliminary science examination 120 guineas. The fee for the curriculum for dental students is 54 guineas on entrance, or two instalments of 40 guineas and 20 guineas.

**ST. THOMAS'S HOSPITAL.**—This hospital, with medical school attached, is situated on the southern Embankment of the Thames, facing the Houses of Parliament, and contains 602 beds, of which about 540 are in constant use. The school buildings, which are separated from the hospital by a quadrangle, comprise numerous theatres, laboratories, and class rooms, which are well adapted for the modern teaching of large bodies of students in all subjects of the medical curriculum. There is a large library and reading-room, and a very complete museum and gymnasium.

**Appointments** are open to all students. A resident assistant physician and a resident assistant surgeon are appointed annually at a salary of £100 with board and lodging; two resident casualty officers at a salary of £100 per annum. Two hospital registrars, at an annual salary of £100 each, are appointed yearly. The tenure of these offices may be renewed for a term not exceeding two years. An obstetric tutor and registrar is appointed each year at an annual salary of £50. Four house physicians, two house physicians to out-patients, four house surgeons, four house surgeons to out-patients, two obstetric house physicians, two ophthalmic house surgeons, and eight clinical assistants in the special departments are appointed every three months.

**Scholarships, Prizes, &c.**—Three entrance scholarships are offered for competition in September, *viz.*, one of £150 and one of £60 in chemistry, physics, and biology at the commencement of the second year; one of £50 open to University students who have passed in anatomy and physiology, for a medical degree in any of the Universities of the United Kingdom, and have not entered as students in any London Medical school. Numerous scholarships, prizes, and medals are open to competition throughout the whole career of a student, including a Fellowship of £100 given by the Salters' Company for research in pharmacology.

Special courses of instruction for the Preliminary Scientific and Intermed., M.B.Lond., for the Oxford and Cambridge examinations, and for the Primary and Final F.R.C.S. are held throughout the year.

A register of approved lodgings is kept by the medical secretary, who has a list of local medical practitioners and others who receive students into their houses. The prospectus of the school may be obtained on application to Mr. Rendle, the medical secretary.

**UNIVERSITY COLLEGE, LONDON, AND HOSPITAL.**—This hospital is situated in Gower Street, not far from Euston Railway terminus. The college in which the classes are held faces the hospital, on the opposite side of the street. The number of beds available for teaching purposes is 191.

**Appointments.**—Eight house physicians, six house surgeons, four senior and four junior obstetric assistants, and two ophthalmic assistants are selected annually by examination from among the senior students, without fee. The house physicians and house surgeons reside in the hospital for a period of six months, and the senior

obstetric assistants for three months, and receive their board and lodging free.

The offices of out-patient physicians' and surgeons' assistants, clinical clerks, surgeons' dressers, and ophthalmic surgeons' assistants are filled by pupils who are also students of the college, without additional fee.

**Scholarships, &c.**—Entrance scholarships (examination begins on September 20th, at 10 o'clock): One of the value of £120, and two of 60 guineas for proficiency in science, the subjects being those of the Preliminary Scientific Examination of the University of London, and two of 80 guineas each, the subjects being anatomy and physiology; the Atkinson-Morley surgical scholarship of £45 a year, tenable for three years; Atchison's scholarship, value £55, tenable for two years; Sharpey physiological scholarship, value about £105 a year; Filliter exhibition for proficiency in pathological anatomy, value £30; Erichsen prize, operating case, value £10 10s., awarded for practical surgery, Dr. Fellow's clinical medals, the Liston gold medal, Alexander Bruce gold medal, Cluff memorial prize, Tuke medals for pathology, class medals, &c., gold and silver medals or other prizes, as well as certificates of honour, are awarded after competitive examinations in particular branches of study. The Tuffnell scholarship of £80 for chemistry, two years; and the Clothworkers' exhibitions in chemistry and physics of £30 each, can also be held in the medical faculty.

**Composition Fees.**—The following have been grouped to meet the requirements of the various examining boards:

**A.**—For the Courses required by the University of London. 1. For the Preliminary Scientific course: 25 guineas, entitling to one attendance. 2. For the Intermediate Course: 60 guineas, if paid in one sum; 62 guineas if paid in two instalments. 3. For the Final M.B., B.S. Course: 80 guineas, if paid in one sum; 82 guineas, if paid in two instalments. This course of instruction is also suitable for the corresponding Examinations at the Universities of Oxford, Cambridge, and Durham.

**B.**—For the Medical education required by the Examining Board in England and the Society of Apothecaries: 4. For the Course required for the First Examination: \*30 guineas entitling to one attendance. 5. For the Second: 50 guineas, if paid in one sum; 51 guineas, if paid in two instalments. 6. For the Course required for the Third Examination: 80 guineas, if paid in one sum; 82 guineas, if paid in two instalments.

The composition fee in each case entitles to attendance on Lectures and Hospital Practice during three years.

**C.**—For Dental Students. Composition fee for the Courses required for the L.D.S., 65 guineas; or exclusive of Chemistry, Practical Chemistry, Physics, and Materia Medica, 50 guineas.

\* Students may repeat attendance at the Courses in Chemistry and Physics for £3 3s. (inclusive) and in Elementary Biology for £2 2s.

**WESTMINSTER HOSPITAL.**—This hospital is conveniently situated, facing the Abbey, and is readily accessible from all parts of the Metropolis. It contains 205 beds for general cases, and all the special departments. New school buildings have been erected close by which afford accommodation for 150 students. The class rooms, dissecting rooms, and lecture theatre are excellent samples of modern erections, affording ample scope for study.

**Appointments.**—Medical and surgical registrars, each £40 per annum; two house physicians, two house surgeons, two assistant house surgeons, and resident obstetric assistant. These officers, except the two first named, are all boarded free of expense. Fourth year's students are appointed to be clinical assistants in the various departments.

**Scholarships, &c.**—(a) Winter Session—The Guthrie scholarship £60, entrance scholarship £40, entrance scholarship £30, dental scholarship £20; subjects, Latin, mathematics, experimental physics, chemistry, and either Greek, French, or German. University

scholarships, £40 and £30; subjects, anatomy and physiology. Natural science scholarship, £60, same as for Prel. Sci. of University of London. Natural science scholarship, £40, chemistry and physics. Free presentation, open to pupils of Epsom Medical College. (b) Summer Session.—Natural science scholarship, £60, same as winter. Natural science scholarship, £40, same as above. Arts scholarship, £60, arts scholarship, £40, University scholarships, £40 and £30, subjects same as in winter session. (c) Prizes.—Treasurers', 10 guineas, for first year's men; Chadwick, 20 guineas for students of any year not exceeding fifth. To be competed for by unqualified men. Bird medal and prize, £14, for students who have completed fourth winter session. Sturges prize in clinical medicine, £8, clinical surgery prize, £5, to be competed for by unqualified men. And class prizes in the various subjects.

**Fees.**—In one payment of 110 guineas, or two payments of 60 guineas each, payable on entrance and at the commencement of second year respectively, or by six payments distributed over six sessions of 25 guineas and 20 guineas alternately. Fees for shorter periods or for single courses may be learned on application to the Dean. Fees for dental students, payable in one sum on entrance, 50 guineas, or in two instalments of £27 10s.

**LONDON SCHOOL OF MEDICINE FOR WOMEN (ROYAL FREE HOSPITAL).**—This school, which is situated in Hunter Street, Brunswick Square, opens at the same time as, and the periods of study, lectures, &c., are similar to those at, the ordinary medical schools. A dissecting-room, physiological, chemical, biological, physical, and pharmaceutical laboratories and library are provided at the school, and clinical lectures are regularly delivered at the Royal Free Hospital close by, which institution is appropriated to the students at the School as a field of practical study; all clerkships and dresserships are open to the students of the School. Resident and other posts are open to the students after qualification. Numerous scholarships and prizes are awarded, particulars of which can be obtained on application.

**Fees.**—The fee for the Intermediate and Final M.B. Lond. Course is £95 if paid in one sum, or £100 if paid in three instalments. The fee for the Course for the Conjoint Colleges of Scotland, &c., including Elementary Science, is £105 if paid in one sum, or £110 if paid in three instalments. The fee for hospital practice and clinical teaching is £40, or £45 if paid in instalments.

Special classes for the Preliminary Scientific examination of the University of London, For the whole course, £25.

### EXTRA-ACADEMICAL INSTITUTIONS IN LONDON.

**NATIONAL DENTAL HOSPITAL.**—This institution is centrally situated (Great Portland Street, W.), and excellent teaching facilities and hospital practice are here obtainable, special demonstrations being given by members of the staff. There are also a mechanical laboratory, bacteriological laboratory, museum, students' common room, a metallurgical laboratory, extraction and stopping rooms, lecture hall, regulations room, &c., all lighted by electricity, and warmed and ventilated after the most approved requirements; in fact, this institution may be pronounced a model dental hospital and school. The winter session commences at the same time as at the medical schools, on October 3rd. The medical tutors hold special classes before each college examination. The prizes include two entrance exhibitions, value £40 and £20, and the Rymer prize of £5 ss., the examinations for which are held in May and October. The fee for two years' hospital practice required by the curriculum, including lectures, is £40. (See advt.)

**LONDON SCHOOL OF DENTAL SURGERY.**—The teaching and hospital practice at this institution, like that at the foregoing, are recognised by the Royal College of Surgeons for the dental diploma. It is situated in Leicester Square, is open daily, and under the supervision of a special staff and house surgeons. The Hospital having been rebuilt recently,

the accommodation is equal to all requirements. There is the Saunders scholarship and Entrance scholarship, value £20 each, the Woodhouse Prize of £10, and other prizes awarded yearly, the Storer Bennett Research scholarship, value £50, awarded triennially, and the five house surgeoncies are filled by students of the hospital holding the L.D.S. Fee for two years' hospital practice required by the curriculum, including lectures, £56 6s. The fee for three years' tuition in mechanical dentistry and the two years' hospital practice as required by the curriculum is £175 if paid in one instalment, or 75 guineas, 50 guineas, and 50 guineas if paid in three instalments. For tuition in mechanical dentistry the fee is 50 guineas per annum.

**LONDON SCHOOL OF TROPICAL MEDICINE.**—This Institution is the outcome of a suggestion by the Right Hon. Joseph Chamberlain, H.M. late Secretary of State for the Colonies, and is situated at the Royal Victoria Docks, in connection with the Seamen's Hospital, than which no more suitable spot could be found, as ships arrive there in great numbers from the Tropics, affording immediate opportunity for the study of tropical diseases. The school buildings are placed within the hospital grounds, and systematic courses of instruction are obtainable from duly authorised teachers throughout the year. Students also have the privilege of attending the medical and surgical practice at the "Dreadnought" Hospital, Greenwich. Information as to fees, &c., can be obtained of the Dean or the Secretary.

**Medical students are admitted to the practice of the following Metropolitan hospitals, to which no medical school is attached. Detailed particulars will be supplied on application to the various secretaries.**

**WEST LONDON HOSPITAL, Hammersmith.**—This contains 154 beds, and has an extensive out-patient department. Dresserships and clinical clerkships may be obtained. Two house surgeons and two house physicians are selected every six months. Special departments have recently been opened for diseases of the throat, ear, skin, and deformities. Electrical and X-ray departments have also been added. The practice of this hospital is reserved exclusively for medical men, junior students not being admitted.

**GREAT NORTHERN CENTRAL HOSPITAL, Holloway Road, N.**—This institution has been recently enlarged, contains 159 beds, and is now recognised for study during the fifth year by the Conjoint Board. The practice of the hospital is open to practitioners and senior students, and clinical and pathological assistants are appointed in the wards and out-patient departments, as in the larger general hospitals.

**BETHLEM ROYAL HOSPITAL.**—Two resident house physicians who have recently obtained their diplomas to practise medicine and surgery are elected every six months, and are provided with apartments, complete board, attendance, washing, and an honorarium of 25 guineas per quarter. The students of certain specified London medical schools receive clinical instruction in the wards of the hospital, and qualified practitioners may attend for a period of three months on payment of a fee. Post-graduate lectures are also given.

**NATIONAL HOSPITAL FOR EPILEPSY AND OTHER DISEASES OF THE NERVOUS SYSTEM, Queen's Square, W.C.,** contains 200 beds. It has on its staff men of European reputation, and the institution is recognised by the Conjoint Board where part of the fifth year of study may be devoted to clinical work. Clinical clerks are appointed to the physicians for out-patients, and courses of lectures and clinical demonstrations are given each year.

**HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton.**—The largest institution for the treatment of affections of the chest in the United Kingdom, there being 318 beds in the two buildings. There are four house physicians, who reside in the

hospital, each for a period of six months. Lectures and demonstrations are given by members of the medical staff on Wednesdays and Fridays at four o'clock, save during the vacations. Terms, £2 2s. for three months; £5 5s. perpetual. This hospital is recognised by the Conjoint Board, the University of London, and the Apothecaries' Society.

**CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST,** Victoria Park.—This is a large and well-equipped hospital at the East End, containing 164 beds. Clinical lectures and demonstrations are given by the members of an exceptionally experienced staff. Fee for three months' attendance on hospital practice, 2 guineas; six months, 3 guineas.

**ROYAL HOSPITAL FOR DISEASES OF THE CHEST,** City Road.—(80 beds).—This hospital has been enlarged by the addition of a very complete out-patients' department, and also by the erection of a new wing, which provides accommodation for 80 in-patients.

#### THROAT AND EAR HOSPITALS.

**METROPOLITAN EAR, NOSE, AND THROAT HOSPITAL.**—The hospital was founded in 1838, and is situated in Grafton Street, Tottenham Court Road. The out-patient department is open daily at 2.30 p.m. to practitioners and students for acquiring clinical instruction and technical knowledge. Operations are performed on in-patients on Tuesdays, Wednesdays, and Thursdays at 9 a.m. Fee for one month's attendance at the hospital one guinea, and for three months two guineas. During the forthcoming session demonstrations will be given by members of the staff on the pathology and treatment of diseases of the ear and respiratory passages. Short practical classes will also be held in clinical pathology and surgical anatomy. Weekly clinical lectures are given by the staff on the special disease treated at the hospital, the date, time, and subject of these lectures are previously announced in the medical journals. Further particulars may be obtained upon application to the Hon. Secretary to the Medical Board, at the hospital.

**CENTRAL LONDON THROAT AND EAR HOSPITAL,** Gray's Inn Road, contains seventeen beds, with an extensive out-patient department recently enlarged. Clinical demonstrations and instruction to qualified practitioners and senior students daily during the hours of the surgeons' visits. Twelve clinical assistants, who must be duly qualified, are elected to assist the surgeons. Operation days—Tuesdays and Fridays, 2 p.m. Fees for the three months' attendance, £3 3s.; six months', £5 5s. Full details of this institution and post-graduate work will be found on reference to our advertising columns or on application to the Dean.

**HOSPITAL FOR DISEASES OF THE THROAT,** Golden Square, W.—This hospital has been recently rebuilt and contains 50 beds. Clinical instruction is given daily in the Out-patient Department on diseases of the nose, throat, and ear. There are nine clinics weekly, and an annual out-patient attendance of nearly 50,000. Major and minor operations daily (Mondays excepted) in different theatres. Four senior and forty-two junior clinical assistants are appointed from among the students to assist the surgeons. Students are admitted to the practice of the hospital at the following fees:—Three months, £5 5s.; six months, £7 7s.; perpetual attendance, £10 10s. Further details can be had by applying to the Dean.

#### WOMEN AND CHILDREN.

**THE HOSPITAL FOR WOMEN,** Soho Square.—The hospital contains 61 beds. In connection with this institution there is now an organised school of gynaecology open to qualified medical men and to students after their third year. Clinical assistants to the physicians and surgeons in the in-patient and out-patient departments are appointed every three months. Fee for the three months' course, and certificate, £8 8s.

**THE SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN,** Lower Seymour Street, W., offers excellent opportunities for clinical study and training in the details of operative gynaecology. The success of the staff in this department have gained for them a European reputation. There are 47 beds.

**HOSPITAL FOR SICK CHILDREN** in Great Ormond Street, Bloomsbury, W.C., and Cromwell House, Highgate.—Fee for three months' attendance, £2 2s.; perpetual, £3 3s. There are now 200 beds, besides 52 additional at the convalescent branch, and it is probably the largest institution of the kind in the world. The practice of the hospital is open to pupils of the different hospitals and medical schools of London and medical practitioners on conditions to be ascertained from the Secretary.

#### EYE HOSPITALS.

**ROYAL LONDON OPHTHALMIC HOSPITAL,** formerly in Moorfields, and recently rebuilt in the City Road, is the largest hospital devoted to this specialty in Great Britain, and contains 138 beds. Students and practitioners are admitted to the practice daily at 9 o'clock. Operations, 10 o'clock and after. Fee for six months, £3 3s.; perpetual, £5 5s. Further particulars of the Secretary.

**ROYAL WESTMINSTER OPHTHALMIC HOSPITAL,** adjoins Charing Cross Hospital in King William Street. It has about 34 beds and a very large out-patient *clinique*. The lectures and demonstrations are arranged with special reference to the requirements of practitioners and senior students. Fee, six months, £3 3s.; perpetual, £5 5s.

**ROYAL EYE HOSPITAL,** St. George's Circus, Southwark.—There are 40 beds and two cots. Fees, £2 2s. for three months, £3 3s. for six months, and £5 5s. perpetual. Courses are held on ophthalmoscopy, refraction, and diseases of the eye; fee, £1 1s. for each course, but perpetual students may attend each course once without extra fee. Pathology class, £1 1s. extra to cover cost of materials.

#### SKIN HOSPITALS.

**ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN.**—Out-patient department, Leicester Square; In-patient department, Uxbridge Road, W. This hospital has a well-equipped in-patient department, with 50 beds. It has a School of Dermatology at 49 Leicester Square, which is conducted by the medical staff of the hospital. A spacious laboratory is also provided. During the past year the free course of Chesterfield Lectures given by Dr. Morgan Dockrell has proved a great success, being well attended by the profession. The next course (free) will commence in October next, and the dates and times will be duly announced in our columns. The Out-patient Department is to be rebuilt immediately. (See advt.)
